SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='image-classification', region='cn-north-1')
```

Registry path	Version	Job types (image scope)		
390948362332.dkr.ecr.cn-1 north-1.amazonaws.com.cn/ image- classification:<tag>		inference, training		

## Inferentia MXNet (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='inferentia-mxnet',region='cn-north-1',version='1.5.1',instance_type='ml.inf1.6xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
472730292857.dkr.ecr.cn-north-1.amazonaws.com.cn/sagemaker-neo-mxnet:<tag>		inference	inf	py3

## Inferentia PyTorch (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='inferentia-pytorch',region='cn-north-1',version='1.5.1',py_version='py3')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
472730292857.dkr.ecr.cn-north-1.amazonaws.com.cn/sagemaker-neo-pytorch:<tag>		inference	inf	py3

## K-Means (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='kmeans',region='cn-north-1')
```

Registry path	Version	Job types (image scope)		
390948362332.dkr.ecr.cn-north-1.amazonaws.com.cn/kmeans:<tag>		inference, training		

## KNN (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='knn',region='cn-north-1')
```

Registry path	Version	Job types (image scope)		
390948362332.dkr.ecr.cn-1 north-1.amazonaws.com.cn/ knn:<tag>		inference, training		

### Linear Learner (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='linear-learner', region='cn-north-1')
```

Registry path	Version	Job types (image scope)		
390948362332.dkr.ecr.cn-1 north-1.amazonaws.com.cn/ linear-learner:<tag>		inference, training		

### MXNet (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='mxnet', region='cn-north-1', version='1.4.1', py_version='py3', image_scope='inference',
    instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
422961961927.dkr.ecr.cn-1 north-1.amazonaws.com.cn/ sagemaker-mxnet-eia:<tag>		eia	CPU	py2, py3

### MXNet Coach (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='coach-mxnet', region='cn-north-1', version='0.11', py_version='py3', image_scope='training', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
422961961927.dkr.ecr.cn-north-1.amazonaws.com.cn/sagemaker-rl-mxnet:coach0.11-<tag>		training	CPU, GPU	py3
422961961927.dkr.ecr.cn-north-1.amazonaws.com.cn/sagemaker-rl-mxnet:coach0.11.0-<tag>		training	CPU, GPU	py3

### Model Monitor (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='model-monitor', region='cn-north-1')
```

Registry path	Version	Job types (image scope)		
453000072557.dkr.ecr.cn-north-1.amazonaws.com.cn/sagemaker-model-monitor-analyzer:<tag>		monitoring		

### NTM (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
```

```
image_uris.retrieve(framework='ntm', region='cn-north-1')
```

Registry path	Version	Job types (image scope)		
390948362332.dkr.ecr.cn-1 north-1.amazonaws.com.cn/ ntm:<tag>		inference, training		

### Neo Image Classification (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='image-classification-neo', region='cn-north-1')
```

Registry path	Version	Job types (image scope)		
472730292857.dkr.ecr.cn-latest north-1.amazonaws.com.cn/ image-classification- neo:<tag>		inference		

### Neo MXNet (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='neo-mxnet', region='cn-north-1', version='1.8', py_version='py3', image_scope='inference',
instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
472730292857.dkr.ecr.cn- north-1.amazonaws.com.cn/ sagemaker- inference- mxnet:<tag>		inference	CPU, GPU	py3

### Neo PyTorch (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='neo-pytorch', region='cn-north-1', version='1.6', image_scope='inference', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
472730292857.dkr.ecr.cn-north-1.amazonaws.com.cn/sagemaker-inference-pytorch:<tag>		inference	CPU, GPU	py3
472730292857.dkr.ecr.cn-north-1.amazonaws.com.cn/sagemaker-inference-pytorch:<tag>		inference	CPU, GPU	py3
472730292857.dkr.ecr.cn-north-1.amazonaws.com.cn/sagemaker-inference-pytorch:<tag>		inference	CPU, GPU	py3

### Neo Tensorflow (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='neo-tensorflow', region='cn-north-1', version='1.15.3', py_version='py3', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
472730292857.dkr.ecr.cn-north-1.amazonaws.com.cn/sagemaker-inference-tensorflow:<tag>		inference	CPU, GPU	py3

### Neo XGBoost (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='xgboost-neo', region='cn-north-1')
```

Registry path	Version	Job types (image scope)		
472730292857.dkr.ecr.cn-latest		inference		
north-1.amazonaws.com.cn/xgboost-neo:<tag>				

## Object Detection (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='object-detection',region='cn-north-1')
```

Registry path	Version	Job types (image scope)		
390948362332.dkr.ecr.cn-1 north-1.amazonaws.com.cn/ object-detection:<tag>		inference, training		

## Object2Vec (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='object2vec',region='cn-north-1')
```

Registry path	Version	Job types (image scope)		
390948362332.dkr.ecr.cn-1 north-1.amazonaws.com.cn/ object2vec:<tag>		inference, training		

## PCA (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='pca',region='cn-north-1')
```

Registry path	Version	Job types (image scope)		
390948362332.dkr.ecr.cn-1 north-1.amazonaws.com.cn/ pca:<tag>		inference, training		

## PyTorch (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='pytorch',region='cn-
north-1',version='1.8.0',py_version='py3',image_scope='inference',
instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
422961961927.dkr.e0.410-north-1.amazonaws.com.cn/sagemaker-pytorch:<tag>		inference	CPU, GPU	py2, py3
422961961927.dkr.e0.410-north-1.amazonaws.com.cn/sagemaker-pytorch:<tag>		training	CPU, GPU	py2, py3
422961961927.dkr.edr.010-north-1.amazonaws.com.cn/sagemaker-pytorch:<tag>		inference	CPU, GPU	py2, py3

727897471807.dkr.edr.311-north-1.amazonaws.com.cn/pytorch-training:<tag>		training	CPU, GPU	py2, py3
727897471807.dkr.edr.410-north-1.amazonaws.com.cn/pytorch-training:<tag>		training	CPU, GPU	py2, py3
727897471807.dkr.edr.510-north-1.amazonaws.com.cn/pytorch-training:<tag>		training	CPU, GPU	py3
727897471807.dkr.edr.610-north-1.amazonaws.com.cn/pytorch-training:<tag>		training	CPU, GPU	py3, py36
727897471807.dkr.edr.711-north-1.amazonaws.com.cn/pytorch-training:<tag>		training	CPU, GPU	py3, py36
727897471807.dkr.edr.810-north-1.amazonaws.com.cn/pytorch-training:<tag>		training	CPU, GPU	py3, py36

Registry path	Version	Job types (image scope)	Processor types	Python versions
727897471807.dkr.ecr.cn-1 north-1.amazonaws.com.cn/ pytorch-training:<tag>		training	CPU, GPU	py3, py36

### Random Cut Forest (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='randomcutforest',region='cn-north-1')
```

Registry path	Version	Job types (image scope)		
390948362332.dkr.ecr.cn-1 north-1.amazonaws.com.cn/ randomcutforest:<tag>		inference, training		

### Scikit-learn (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='sklearn',region='cn-north-1',version='0.23-1',image_scope='inference')
```

Registry path	Version	Job types (image scope)		
450853457545.dkr.ecr.cn-0.20.0 north-1.amazonaws.com.cn/ sagemaker-scikit-learn:<tag>		inference, training		
450853457545.dkr.ecr.cn-0.23-1 north-1.amazonaws.com.cn/ sagemaker-scikit-learn:<tag>		inference, training		

### Semantic Segmentation (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='semantic-segmentation',region='cn-north-1')
```

Registry path	Version	Job types (image scope)		
390948362332.dkr.ecr.cn-1 north-1.amazonaws.com.cn/ semantic-segmentation:<tag>		inference, training		

## Seq2Seq (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='seq2seq',region='cn-north-1')
```

Registry path	Version	Job types (image scope)		
390948362332.dkr.ecr.cn-1 north-1.amazonaws.com.cn/ seq2seq:<tag>		inference, training		

## Spark (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='spark',region='cn-north-1',version='3.0',image_scope='processing')
```

Registry path	Version	Job types (image scope)		
671472414489.dkr.ecr.cn-2.4 north-1.amazonaws.com.cn/ sagemaker-spark-processing:<tag>		processing		
671472414489.dkr.ecr.cn-3.0 north-1.amazonaws.com.cn/ sagemaker-spark-processing:<tag>		processing		

## SparkML Serving (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='sparkml-serving',region='cn-north-1',version='2.4')
```

Registry path	Version	Job types (image scope)		
450853457545.dkr.ecr.cn-2.2 north-1.amazonaws.com.cn/ sagemaker-sparkml- serving:<tag>		inference		
450853457545.dkr.ecr.cn-2.4 north-1.amazonaws.com.cn/ sagemaker-sparkml- serving:<tag>		inference		

## Tensorflow (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='tensorflow', region='cn-north-1', version='1.12.0', image_scope='inference', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions

### Tensorflow Coach (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='coach-tensorflow', region='cn-north-1', version='1.0.0', image_scope='training', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
422961961927.dkr.e0.10-north-1.amazonaws.com.cn/sagemaker-rl-tensorflow:coach0.10-<tag>		training	CPU, GPU	py3
422961961927.dkr.e0.10.1-north-1.amazonaws.com.cn/sagemaker-rl-tensorflow:coach0.10.1-<tag>		training	CPU, GPU	py3
422961961927.dkr.e0.11-north-1.amazonaws.com.cn/sagemaker-rl-tensorflow:coach0.11-<tag>		training	CPU, GPU	py3
422961961927.dkr.e0.11.0-north-1.amazonaws.com.cn/sagemaker-rl-tensorflow:coach0.11.0-<tag>		training	CPU, GPU	py3
422961961927.dkr.e0.11.1-north-1.amazonaws.com.cn/sagemaker-rl-		training	CPU, GPU	py3

Registry path	Version	Job types (image scope)	Processor types	Python versions
tensorflow:coach0.11.1- <i>&lt;tag&gt;</i>				

## Tensorflow Inference (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='inferentia-tensorflow',region='cn-north-1',version='1.15.0',instance_type='ml.inf1.6xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
472730292857.dkr.e0r.t5.0 north-1.amazonaws.com.cn/ sagemaker-neo-tensorflow:<tag>		inference	inf	py3

## Tensorflow Ray (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='ray-tensorflow',region='cn-north-1',version='0.8.5',instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
422961961927.dkr.e0r.t5.0 north-1.amazonaws.com.cn/ sagemaker-rl-tensorflow:ray0.5-<tag>		training	CPU, GPU	py3
422961961927.dkr.e0r.t5.3 north-1.amazonaws.com.cn/ sagemaker-rl-tensorflow:ray0.5.3-<tag>		training	CPU, GPU	py3
422961961927.dkr.e0r.t5.0 north-1.amazonaws.com.cn/ sagemaker-rl-tensorflow:ray0.6-<tag>		training	CPU, GPU	py3
422961961927.dkr.e0r.t5.0 north-1.amazonaws.com.cn/ sagemaker-rl-		training	CPU, GPU	py3

Registry path	Version	Job types (image scope)	Processor types	Python versions
tensorflow:ray0.6.5-<tag>				

## XGBoost (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='xgboost', region='cn-north-1', version='1.2-1')
```

Registry path	Version	Job types (image scope)		
390948362332.dkr.ecr.cn-1 north-1.amazonaws.com.cn/ xgboost:<tag>		inference, training		
450853457545.dkr.ecr.cn-0.90-1 north-1.amazonaws.com.cn/ sagemaker- xgboost:<tag>		inference, training		
450853457545.dkr.ecr.cn-0.90-2 north-1.amazonaws.com.cn/ sagemaker- xgboost:<tag>		inference, training		
450853457545.dkr.ecr.cn-1.0-1 north-1.amazonaws.com.cn/ sagemaker- xgboost:<tag>		inference, training		
450853457545.dkr.ecr.cn-1.2-1 north-1.amazonaws.com.cn/ sagemaker- xgboost:<tag>		inference, training		
450853457545.dkr.ecr.cn-1.2-2 north-1.amazonaws.com.cn/ sagemaker- xgboost:<tag>		inference, training		
450853457545.dkr.ecr.cn-1.3-1 north-1.amazonaws.com.cn/ sagemaker- xgboost:<tag>		inference, training		

## Docker Registry Paths and Example Code for China (Ningxia) (cn-northwest-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

### Topics

- [BlazingText \(algorithm\) \(p. 1084\)](#)
- [Chainer \(DLC\) \(p. 1085\)](#)

### [BlazingText \(algorithm\)](#)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='blazingtext', region='cn-northwest-1')
```

Registry path	Version	Job types (image scope)		
387376663083.dkr.ecr.cn-1 northwest-1.amazonaws.com.cn/ blazingtext:<tag>		inference, training		

## Chainer (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='chainer', region='cn-northwest-1', version='5.0.0', py_version='py3', image_scope='inference', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
423003514399.dkr.ecr.cn-0 northwest-1.amazonaws.com.cn/ sagemaker-chainer:<tag>		inference, training	CPU, GPU	py2, py3
423003514399.dkr.ecr.cn-1 northwest-1.amazonaws.com.cn/ sagemaker-chainer:<tag>		inference, training	CPU, GPU	py2, py3
423003514399.dkr.ecr.cn-2 northwest-1.amazonaws.com.cn/ sagemaker-chainer:<tag>		inference, training	CPU, GPU	py2, py3

## Clarify (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='clarify', region='cn-northwest-1', version='1.0', image_scope='processing')
```

Registry path	Version	Job types (image scope)		
122578899357.dkr.ecr.cn-1.0 northwest-1.amazonaws.com.cn/ sagemaker-clarify-processing:<tag>		processing		

## Data Wrangler (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='data-wrangler',region='cn-northwest-1')
```

Registry path	Version	Job types (image scope)		
249157047649.dkr.ecr.cn-1.x northwest-1.amazonaws.com.cn/ sagemaker- data-wrangler- container:<tag>		processing		

## Debugger (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='debugger',region='cn-northwest-1')
```

Registry path	Version	Job types (image scope)		
658757709296.dkr.ecr.cn-latest northwest-1.amazonaws.com.cn/ sagemaker-debugger- rules:<tag>		debugger		

## DeepAR Forecasting (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='forecasting-deepar',region='cn-northwest-1')
```

Registry path	Version	Job types (image scope)		
387376663083.dkr.ecr.cn-1 northwest-1.amazonaws.com.cn/ forecasting- deepar:<tag>		inference, training		

## Factorization Machines (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='factorization-machines',region='cn-northwest-1')
```

Registry path	Version	Job types (image scope)		
387376663083.dkr.ecr.cn-1 northwest-1.amazonaws.com.cn/ factorization- machines:<tag>		inference, training		

## Hugging Face (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='huggingface', region='cn-northwest-1', version='4.4.2', image_scope='training', base_framework_version='tensorflow2.4.1')
```

Registry path	Version	Job types (image scope)		
727897471807.dkr.ecr.cn-4.4.2 northwest-1.amazonaws.com.cn/ huggingface-pytorch- training:<tag>		training		
727897471807.dkr.ecr.cn-4.5.0 northwest-1.amazonaws.com.cn/ huggingface-pytorch- training:<tag>		training		
727897471807.dkr.ecr.cn-4.4.2 northwest-1.amazonaws.com.cn/ huggingface- tensorflow- training:<tag>		training		
727897471807.dkr.ecr.cn-4.5.0 northwest-1.amazonaws.com.cn/ huggingface- tensorflow- training:<tag>		training		

## IP Insights (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='ipinsights', region='cn-northwest-1')
```

Registry path	Version	Job types (image scope)		
387376663083.dkr.ecr.cn-1 northwest-1.amazonaws.com.cn/ ipinsights:<tag>		inference, training		

## Image classification (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='image-classification', region='cn-northwest-1')
```

Registry path	Version	Job types (image scope)		
387376663083.dkr.ecr.cn-1 northwest-1.amazonaws.com.cn/ image- classification:<tag>		inference, training		

## Inferentia MXNet (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='inferentia-mxnet', region='cn-  
northwest-1', version='1.5.1', instance_type='ml.inf1.6xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
474822919863.dkr.ecr.cn-1 northwest-1.amazonaws.com.cn/ sagemaker-neo- mxnet:<tag>		inference	inf	py3

## Inferentia PyTorch (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='inferentia-pytorch', region='cn-  
northwest-1', version='1.5.1', py_version='py3')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
474822919863.dkr.ecr.cn-1 northwest-1.amazonaws.com.cn/ sagemaker-neo- pytorch:<tag>		inference	inf	py3

## K-Means (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
```

```
image_uris.retrieve(framework='kmeans', region='cn-northwest-1')
```

Registry path	Version	Job types (image scope)		
387376663083.dkr.ecr.cn-1 northwest-1.amazonaws.com.cn/ kmeans:<tag>		inference, training		

### KNN (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='knn', region='cn-northwest-1')
```

Registry path	Version	Job types (image scope)		
387376663083.dkr.ecr.cn-1 northwest-1.amazonaws.com.cn/ knn:<tag>		inference, training		

### Linear Learner (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='linear-learner', region='cn-northwest-1')
```

Registry path	Version	Job types (image scope)		
387376663083.dkr.ecr.cn-1 northwest-1.amazonaws.com.cn/ linear-learner:<tag>		inference, training		

### MXNet (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='mxnet', region='cn-northwest-1', version='1.4.1', py_version='py3', image_scope='inference',
instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
423003514399.dkr.ecr.cn-1 northwest-1.amazonaws.com.cn/		eia	CPU	py2, py3

Registry path	Version	Job types (image scope)	Processor types	Python versions
sagemaker-mxnet-eia:<tag>				
423003514399.dkr.edr.410-northwest-1.amazonaws.com.cn/sagemaker-mxnet-serving-eia:<tag>		eia	CPU	py2, py3
423003514399.dkr.edr.410-northwest-1.amazonaws.com.cn/sagemaker-mxnet-serving:<tag>		inference	CPU, GPU	py2, py3

## MXNet Coach (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='coach-mxnet', region='cn-northwest-1', version='0.11', py_version='py3', image_scope='training', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
423003514399.dkr.e0.110-northwest-1.amazonaws.com.cn/sagemaker-rl-mxnet:coach0.11-<tag>		training	CPU, GPU	py3
423003514399.dkr.e0.110.0-northwest-1.amazonaws.com.cn/sagemaker-rl-mxnet:coach0.11.0-<tag>		training	CPU, GPU	py3

## Model Monitor (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
```

```
image_uris.retrieve(framework='model-monitor',region='cn-northwest-1')
```

Registry path	Version	Job types (image scope)		
453252182341.dkr.ecr.cn-northwest-1.amazonaws.com.cn/sagemaker-model-monitor-analyzer:<tag>		monitoring		

### NTM (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='ntm',region='cn-northwest-1')
```

Registry path	Version	Job types (image scope)		
387376663083.dkr.ecr.cn-1northwest-1.amazonaws.com.cn/ntm:<tag>		inference, training		

### Neo Image Classification (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='image-classification-neo',region='cn-northwest-1')
```

Registry path	Version	Job types (image scope)		
474822919863.dkr.ecr.cn-latestnorthwest-1.amazonaws.com.cn/image-classification-neo:<tag>		inference		

### Neo MXNet (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='neo-mxnet',region='cn-northwest-1',version='1.8',py_version='py3',image_scope='inference',instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
474822919863.dkr.ecr.cn-northwest-1.amazonaws.com.cn/sagemaker-inference-mxnet:<tag>		inference	CPU, GPU	py3

### Neo PyTorch (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='neo-pytorch', region='cn-northwest-1', version='1.6', image_scope='inference', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
474822919863.dkr.ecr.cn-northwest-1.amazonaws.com.cn/sagemaker-inference-pytorch:<tag>		inference	CPU, GPU	py3
474822919863.dkr.ecr.cn-northwest-1.amazonaws.com.cn/sagemaker-inference-pytorch:<tag>		inference	CPU, GPU	py3
474822919863.dkr.ecr.cn-northwest-1.amazonaws.com.cn/sagemaker-inference-pytorch:<tag>		inference	CPU, GPU	py3

### Neo Tensorflow (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='neo-tensorflow', region='cn-northwest-1', version='1.15.3', py_version='py3', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
474822919863.dkr.ecr.cn-northwest-1.amazonaws.com.cn/sagemaker-inference-tensorflow:<tag>		inference	CPU, GPU	py3

## Neo XGBoost (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='xgboost-neo', region='cn-northwest-1')
```

Registry path	Version	Job types (image scope)		
474822919863.dkr.ecr.cn-latest northwest-1.amazonaws.com.cn/ xgboost-neo:<tag>		inference		

## Object Detection (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='object-detection', region='cn-northwest-1')
```

Registry path	Version	Job types (image scope)		
387376663083.dkr.ecr.cn-1 northwest-1.amazonaws.com.cn/ object-detection:<tag>		inference, training		

## Object2Vec (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='object2vec', region='cn-northwest-1')
```

Registry path	Version	Job types (image scope)		
387376663083.dkr.ecr.cn-1 northwest-1.amazonaws.com.cn/ object2vec:<tag>		inference, training		

## PCA (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='pca', region='cn-northwest-1')
```

Registry path	Version	Job types (image scope)		
387376663083.dkr.ecr.cn-1 northwest-1.amazonaws.com.cn/ pca:<tag>		inference, training		

## PyTorch (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='pytorch', region='cn-northwest-1', version='1.8.0', py_version='py3', image_scope='inference',
instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions

## Random Cut Forest (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='randomcutforest', region='cn-northwest-1')
```

Registry path	Version	Job types (image scope)		
387376663083.dkr.ecr.cn-1-northwest-1.amazonaws.com.cn/randomcutforest:<tag>		inference, training		

## Scikit-learn (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='sklearn', region='cn-northwest-1', version='0.23-1', image_scope='inference')
```

Registry path	Version	Job types (image scope)		
451049120500.dkr.ecr.cn-0.20.0-northwest-1.amazonaws.com.cn/		inference, training		

Registry path	Version	Job types (image scope)		
sagemaker-scikit-learn:<tag>				
451049120500.dkr.ecr.cn-0.23-1 northwest-1.amazonaws.com.cn/ sagemaker-scikit-learn:<tag>		inference, training		

### Semantic Segmentation (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='semantic-segmentation', region='cn-northwest-1')
```

Registry path	Version	Job types (image scope)		
387376663083.dkr.ecr.cn-1 northwest-1.amazonaws.com.cn/ semantic-segmentation:<tag>		inference, training		

### Seq2Seq (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='seq2seq', region='cn-northwest-1')
```

Registry path	Version	Job types (image scope)		
387376663083.dkr.ecr.cn-1 northwest-1.amazonaws.com.cn/ seq2seq:<tag>		inference, training		

### Spark (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='spark', region='cn-northwest-1', version='3.0', image_scope='processing')
```

Registry path	Version	Job types (image scope)		
844356804704.dkr.ecr.cn-2.4 northwest-1.amazonaws.com.cn/		processing		

Registry path	Version	Job types (image scope)		
sagemaker-spark-processing:<tag>				
844356804704.dkr.ecr.cn-3.0 northwest-1.amazonaws.com.cn/ sagemaker-spark-processing:<tag>		processing		

## SparkML Serving (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='sparkml-serving', region='cn-northwest-1', version='2.4')
```

Registry path	Version	Job types (image scope)		
451049120500.dkr.ecr.cn-2.2 northwest-1.amazonaws.com.cn/ sagemaker-sparkml-serving:<tag>		inference		
451049120500.dkr.ecr.cn-2.4 northwest-1.amazonaws.com.cn/ sagemaker-sparkml-serving:<tag>		inference		

## Tensorflow (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='tensorflow', region='cn-northwest-1', version='1.12.0', image_scope='inference', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions

### Tensorflow Coach (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='coach-tensorflow',region='cn-northwest-1',version='1.0.0',image_scope='training',instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
423003514399.dkr.e0.10-northwest-1.amazonaws.com.cn/sagemaker-rl-		training	CPU, GPU	py3

Registry path	Version	Job types (image scope)	Processor types	Python versions
tensorflow:coach0.10-<tag>				
423003514399.dkr.e0.10.1 northwest-1.amazonaws.com.cn/ sagemaker-rl- tensorflow:coach0.10.1-<tag>		training	CPU, GPU	py3
423003514399.dkr.e0.11- northwest-1.amazonaws.com.cn/ sagemaker-rl- tensorflow:coach0.11-<tag>		training	CPU, GPU	py3
423003514399.dkr.e0.11.0 northwest-1.amazonaws.com.cn/ sagemaker-rl- tensorflow:coach0.11.0-<tag>		training	CPU, GPU	py3
423003514399.dkr.e0.11.1 northwest-1.amazonaws.com.cn/ sagemaker-rl- tensorflow:coach0.11.1-<tag>		training	CPU, GPU	py3

## Tensorflow Inference (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='inferentia-tensorflow', region='cn-northwest-1', version='1.15.0', instance_type='ml.inf1.6xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
474822919863.dkr.e0.15.0 northwest-1.amazonaws.com.cn/ sagemaker-neo- tensorflow:<tag>		inference	inf	py3

## Tensorflow Ray (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='ray-tensorflow', region='cn-northwest-1', version='0.8.5', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
423003514399.dkr.ecr.cn-northwest-1.amazonaws.com.cn/sagemaker-rl-tensorflow:ray0.5-<tag>		training	CPU, GPU	py3
423003514399.dkr.ecr.cn-northwest-1.amazonaws.com.cn/sagemaker-rl-tensorflow:ray0.5.3-<tag>		training	CPU, GPU	py3
423003514399.dkr.ecr.cn-northwest-1.amazonaws.com.cn/sagemaker-rl-tensorflow:ray0.6-<tag>		training	CPU, GPU	py3
423003514399.dkr.ecr.cn-northwest-1.amazonaws.com.cn/sagemaker-rl-tensorflow:ray0.6.5-<tag>		training	CPU, GPU	py3

## XGBoost (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='xgboost',region='cn-northwest-1',version='1.2-1')
```

Registry path	Version	Job types (image scope)		
387376663083.dkr.ecr.cn-1northwest-1.amazonaws.com.cn/xgboost:<tag>		inference, training		
451049120500.dkr.ecr.cn-0.90-1northwest-1.amazonaws.com.cn/sagemaker-xgboost:<tag>		inference, training		
451049120500.dkr.ecr.cn-0.90-2northwest-1.amazonaws.com.cn/sagemaker-xgboost:<tag>		inference, training		
451049120500.dkr.ecr.cn-1.0-1northwest-1.amazonaws.com.cn/sagemaker-xgboost:<tag>		inference, training		

Registry path	Version	Job types (image scope)		
451049120500.dkr.ecr.cn-1.2-1 northwest-1.amazonaws.com.cn/ sagemaker- xgboost:<tag>		inference, training		
451049120500.dkr.ecr.cn-1.2-2 northwest-1.amazonaws.com.cn/ sagemaker- xgboost:<tag>		inference, training		
451049120500.dkr.ecr.cn-1.3-1 northwest-1.amazonaws.com.cn/ sagemaker- xgboost:<tag>		inference, training		

### Docker Registry Paths and Example Code for Europe (Frankfurt) (eu-central-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

#### Topics

- [BlazingText \(algorithm\) \(p. 1111\)](#)
- [Chainer \(DLC\) \(p. 1111\)](#)

### [BlazingText \(algorithm\)](#)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='blazingtext', region='eu-central-1')
```

Registry path	Version	Job types (image scope)		
813361260812.dkr.ecr.eu-central-1.amazonaws.com/blazingtext:<tag>		inference, training		

### [Chainer \(DLC\)](#)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='chainer', region='eu-central-1', version='5.0.0', py_version='py3', image_scope='inference', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
520713654638.dkr.ecr.eu-central-1.amazonaws.com/sagemaker-chainer:<tag>	4.0.0	inference, training	CPU, GPU	py2, py3

Registry path	Version	Job types (image scope)	Processor types	Python versions
520713654638.dkr.ecr.eu-central-1.amazonaws.com/sagemaker-chainer:<tag>	4.1.0	inference, training	CPU, GPU	py2, py3
520713654638.dkr.ecr.eu-central-1.amazonaws.com/sagemaker-chainer:<tag>	5.0.0	inference, training	CPU, GPU	py2, py3

### Clarify (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='clarify', region='eu-central-1', version='1.0', image_scope='processing')
```

Registry path	Version	Job types (image scope)		
017069133835.dkr.ecr.eu-1.0-central-1.amazonaws.com/sagemaker-clarify-processing:<tag>		processing		

### Data Wrangler (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='data-wrangler', region='eu-central-1')
```

Registry path	Version	Job types (image scope)		
024640144536.dkr.ecr.eu-1.x-central-1.amazonaws.com/sagemaker-data-wrangler-container:<tag>		processing		

### Debugger (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='debugger', region='eu-central-1')
```

Registry path	Version	Job types (image scope)		
482524230118.dkr.ecr.eu-central-1.amazonaws.com/sagemaker-debugger-rules:<tag>		debugger		

### DeepAR Forecasting (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='forecasting-deepar', region='eu-central-1')
```

Registry path	Version	Job types (image scope)		
495149712605.dkr.ecr.eu-central-1.amazonaws.com/forecasting-deepar:<tag>		inference, training		

### Factorization Machines (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='factorization-machines', region='eu-central-1')
```

Registry path	Version	Job types (image scope)		
664544806723.dkr.ecr.eu-central-1.amazonaws.com/factorization-machines:<tag>		inference, training		

### Hugging Face (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='huggingface', region='eu-central-1', version='4.4.2', image_scope='training', base_framework_version='tensorflow2.4.1')
```

Registry path	Version	Job types (image scope)		
763104351884.dkr.ecr.eu-central-1.amazonaws.com/	4.4.2	training		

Registry path	Version	Job types (image scope)		
huggingface-pytorch-training:<tag>				
763104351884.dkr.ecr.eu-4.5.0 central-1.amazonaws.com/ huggingface-pytorch-training:<tag>		training		
763104351884.dkr.ecr.eu-4.4.2 central-1.amazonaws.com/ huggingface-tensorflow-training:<tag>		training		
763104351884.dkr.ecr.eu-4.5.0 central-1.amazonaws.com/ huggingface-tensorflow-training:<tag>		training		

## IP Insights (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='ipinsights', region='eu-central-1')
```

Registry path	Version	Job types (image scope)		
664544806723.dkr.ecr.eu-1 central-1.amazonaws.com/ ipinsights:<tag>		inference, training		

## Image classification (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='image-classification', region='eu-central-1')
```

Registry path	Version	Job types (image scope)		
813361260812.dkr.ecr.eu-1 central-1.amazonaws.com/ image-classification:<tag>		inference, training		

## Inferentia MXNet (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='inferentia-mxnet',region='eu-central-1',version='1.5.1',instance_type='ml.inf1.6xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
746233611703.dkr.ecr.eu-central-1.amazonaws.com/sagemaker-neo-mxnet:<tag>		inference	inf	py3

## Inferentia PyTorch (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='inferentia-pytorch',region='eu-central-1',version='1.5.1',py_version='py3')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
746233611703.dkr.ecr.eu-central-1.amazonaws.com/sagemaker-neo-pytorch:<tag>		inference	inf	py3

## K-Means (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='kmeans',region='eu-central-1')
```

Registry path	Version	Job types (image scope)		
664544806723.dkr.ecr.eu-central-1.amazonaws.com/kmeans:<tag>		inference, training		

## KNN (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='knn',region='eu-central-1')
```

Registry path	Version	Job types (image scope)		
664544806723.dkr.ecr.eu-central-1.amazonaws.com/knn:<tag>		inference, training		

### LDA (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='lda', region='eu-central-1')
```

Registry path	Version	Job types (image scope)		
353608530281.dkr.ecr.eu-central-1.amazonaws.com/lda:<tag>		inference, training		

### Linear Learner (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='linear-learner', region='eu-central-1')
```

Registry path	Version	Job types (image scope)		
664544806723.dkr.ecr.eu-central-1.amazonaws.com/linear-learner:<tag>		inference, training		

### MXNet (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='mxnet', region='eu-central-1', version='1.4.1', py_version='py3', image_scope='inference',
instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
520713654638.dkr.ecr.eu-central-1.amazonaws.com/sagemaker-mxnet-eia:<tag>		eia	CPU	py2, py3

Registry path	Version	Job types (image scope)	Processor types	Python versions
520713654638.dkr.e <u>40</u> -central-1.amazonaws.com/sagemaker-mxnet-serving-eia:<tag>		eia	CPU	py2, py3
520713654638.dkr.e <u>40</u> -central-1.amazonaws.com/sagemaker-mxnet-serving:<tag>		inference	CPU, GPU	py2, py3
520713654638.dkr.e <u>41</u> -central-1.amazonaws.com/sagemaker-mxnet-serving:<tag>		inference	CPU, GPU	py2
520713654638.dkr.e <u>0.12.1</u> -central-1.amazonaws.com/sagemaker-mxnet:<tag>		inference	CPU, GPU	py2, py3
520713654638.dkr.e <u>0.12.1</u> -central-1.amazonaws.com/sagemaker-mxnet:<tag>		training	CPU, GPU	py2, py3
520713654638.dkr.e <u>0.00</u> -central-1.amazonaws.com/sagemaker-mxnet:<tag>		inference	CPU, GPU	py2, py3
520713654638.dkr.e <u>0.00</u> -central-1.amazonaws.com/sagemaker-mxnet:<tag>		training	CPU, GPU	py2, py3
520713654638.dkr.e <u>0.10</u> -central-1.amazonaws.com/sagemaker-mxnet:<tag>		inference	CPU, GPU	py2, py3
520713654638.dkr.e <u>0.10</u> -central-1.amazonaws.com/sagemaker-mxnet:<tag>		training	CPU, GPU	py2, py3
520713654638.dkr.e <u>0.20</u> -central-1.amazonaws.com/sagemaker-mxnet:<tag>		inference	CPU, GPU	py2, py3
520713654638.dkr.e <u>0.20</u> -central-1.amazonaws.com/sagemaker-mxnet:<tag>		training	CPU, GPU	py2, py3

Registry path	Version	Job types (image scope)	Processor types	Python versions
520713654638.dkr.e <u>5.0</u> -central-1.amazonaws.com/sagemaker-mxnet:<tag>		inference	CPU, GPU	py2, py3
520713654638.dkr.e <u>5.0</u> -central-1.amazonaws.com/sagemaker-mxnet:<tag>		training	CPU, GPU	py2, py3
520713654638.dkr.e <u>5.0</u> -central-1.amazonaws.com/sagemaker-mxnet:<tag>		training	CPU, GPU	py2, py3
520713654638.dkr.e <u>5.1</u> -central-1.amazonaws.com/sagemaker-mxnet:<tag>		training	CPU, GPU	py2
763104351884.dkr.e <u>5.1</u> -central-1.amazonaws.com/mxnet-inference-eia:<tag>		eia	CPU	py2, py3

763104351884.dkr.e <u>5.0</u> -central-1.amazonaws.com/mxnet-inference-eia:<tag>		eia	CPU	py3
763104351884.dkr.e <u>5.1</u> -central-1.amazonaws.com/mxnet-inference:<tag>		inference	CPU, GPU	py3
763104351884.dkr.e <u>5.0</u> -central-1.amazonaws.com/mxnet-inference:<tag>		inference	CPU, GPU	py2, py3
763104351884.dkr.e <u>5.0</u> -central-1.amazonaws.com/mxnet-inference:<tag>		inference	CPU, GPU	py3
763104351884.dkr.e <u>5.0</u> -central-1.amazonaws.com/mxnet-inference:<tag>		inference	CPU, GPU	py37

Registry path	Version	Job types (image scope)	Processor types	Python versions
763104351884.dkr.e <u>u</u> -central-1.amazonaws.com/mxnet-training:<tag>		training	CPU, GPU	py3
763104351884.dkr.e <u>u</u> -central-1.amazonaws.com/mxnet-training:<tag>		training	CPU, GPU	py2, py3
763104351884.dkr.e <u>u</u> -central-1.amazonaws.com/mxnet-training:<tag>		training	CPU, GPU	py3
763104351884.dkr.e <u>u</u> -central-1.amazonaws.com/mxnet-training:<tag>		training	CPU, GPU	py37

## MXNet Coach (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='coach-mxnet', region='eu-central-1', version='0.11', py_version='py3', image_scope='training', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
520713654638.dkr.e <u>u</u> -central-1.amazonaws.com/sagemaker-rl-mxnet:coach0.11-<tag>		training	CPU, GPU	py3
520713654638.dkr.e <u>u</u> -central-1.amazonaws.com/sagemaker-rl-mxnet:coach0.11.0-<tag>		training	CPU, GPU	py3

## Model Monitor (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='model-monitor', region='eu-central-1')
```

Registry path	Version	Job types (image scope)		
048819808253.dkr.ecr.eu-central-1.amazonaws.com/sagemaker-model-monitor-analyzer:<tag>		monitoring		

### NTM (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='ntm', region='eu-central-1')
```

Registry path	Version	Job types (image scope)		
664544806723.dkr.ecr.eu-central-1.amazonaws.com/ntm:<tag>		inference, training		

### Neo Image Classification (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='image-classification-neo', region='eu-central-1')
```

Registry path	Version	Job types (image scope)		
746233611703.dkr.ecr.eu-central-1.amazonaws.com/image-classification-neo:<tag>	latest	inference		

### Neo MXNet (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='neo-mxnet', region='eu-central-1', version='1.8', py_version='py3', image_scope='inference', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
746233611703.dkr.ecr.eu-central-1.amazonaws.com/		inference	CPU, GPU	py3

Registry path	Version	Job types (image scope)	Processor types	Python versions
sagemaker-inference-mxnet:<tag>				

## Neo PyTorch (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='neo-pytorch', region='eu-central-1', version='1.6', image_scope='inference', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
746233611703.dkr.ecr.eu-central-1.amazonaws.com/sagemaker-inference-pytorch:<tag>		inference	CPU, GPU	py3
746233611703.dkr.ecr.eu-central-1.amazonaws.com/sagemaker-inference-pytorch:<tag>		inference	CPU, GPU	py3
746233611703.dkr.ecr.eu-central-1.amazonaws.com/sagemaker-inference-pytorch:<tag>		inference	CPU, GPU	py3

## Neo Tensorflow (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='neo-tensorflow', region='eu-central-1', version='1.15.3', py_version='py3', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
746233611703.dkr.ecr.eu-central-1.amazonaws.com/sagemaker-inference-tensorflow:<tag>		inference	CPU, GPU	py3

## Neo XGBoost (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='xgboost-neo', region='eu-central-1')
```

Registry path	Version	Job types (image scope)		
746233611703.dkr.ecr.eu-central-1.amazonaws.com/xgboost-neo:<tag>		inference		

## Object Detection (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='object-detection', region='eu-central-1')
```

Registry path	Version	Job types (image scope)		
813361260812.dkr.ecr.eu-central-1.amazonaws.com/object-detection:<tag>		inference, training		

## Object2Vec (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='object2vec', region='eu-central-1')
```

Registry path	Version	Job types (image scope)		
664544806723.dkr.ecr.eu-central-1.amazonaws.com/object2vec:<tag>		inference, training		

## PCA (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='pca', region='eu-central-1')
```

Registry path	Version	Job types (image scope)		
664544806723.dkr.ecr.eu-central-1.amazonaws.com/pca:<tag>		inference, training		

## PyTorch (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='pytorch', region='eu-central-1', version='1.8.0', py_version='py3', image_scope='inference',
instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
520713654638.dkr.e0.40-central-1.amazonaws.com/sagemaker-pytorch:<tag>		inference	CPU, GPU	py2, py3

### Random Cut Forest (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='randomcutforest', region='eu-central-1')
```

Registry path	Version	Job types (image scope)		
664544806723.dkr.ecr.eu-central-1.amazonaws.com/randomcutforest:<tag>		inference, training		

### Ray PyTorch (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='ray-pytorch', region='eu-central-1', version='0.8.5', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
462105765813.dkr.ecr.eu-central-1.amazonaws.com/		training	CPU, GPU	py36

Registry path	Version	Job types (image scope)	Processor types	Python versions
sagemaker-rl-ray-container:ray-0.8.5-torch-<tag>				

### Scikit-learn (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='sklearn',region='eu-central-1',version='0.23-1',image_scope='inference')
```

Registry path	Version	Job types (image scope)		
492215442770.dkr.ecr.eu-central-1.amazonaws.com/sagemaker-scikit-learn:<tag>		inference, training		
492215442770.dkr.ecr.eu-central-1.amazonaws.com/sagemaker-scikit-learn:<tag>		inference, training		

### Semantic Segmentation (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='semantic-segmentation',region='eu-central-1')
```

Registry path	Version	Job types (image scope)		
813361260812.dkr.ecr.eu-central-1.amazonaws.com/semantic-segmentation:<tag>		inference, training		

### Seq2Seq (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='seq2seq',region='eu-central-1')
```

Registry path	Version	Job types (image scope)		
813361260812.dkr.ecr.eu-1 central-1.amazonaws.com/ seq2seq:<tag>		inference, training		

## Spark (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='spark', region='eu-central-1', version='3.0', image_scope='processing')
```

Registry path	Version	Job types (image scope)		
906073651304.dkr.ecr.eu-2.4 central-1.amazonaws.com/ sagemaker-spark-processing:<tag>		processing		
906073651304.dkr.ecr.eu-3.0 central-1.amazonaws.com/ sagemaker-spark-processing:<tag>		processing		

## SparkML Serving (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='sparkml-serving', region='eu-central-1', version='2.4')
```

Registry path	Version	Job types (image scope)		
492215442770.dkr.ecr.eu-2.2 central-1.amazonaws.com/ sagemaker-sparkml-serving:<tag>		inference		
492215442770.dkr.ecr.eu-2.4 central-1.amazonaws.com/ sagemaker-sparkml-serving:<tag>		inference		

## Tensorflow (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
```

```
image_uris.retrieve(framework='tensorflow', region='eu-central-1', version='1.12.0', image_scope='inference', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions

520713654638.dkr.e0.11.0-central-1.amazonaws.com/sagemaker-rl-tensorflow:coach0.11.0-<tag>		training	CPU, GPU	py3
520713654638.dkr.e0.11.1-central-1.amazonaws.com/sagemaker-rl-tensorflow:coach0.11.1-<tag>		training	CPU, GPU	py3

## Tensorflow Inferentia (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='inferentia-tensorflow',region='eu-central-1',version='1.15.0',instance_type='ml.inf1.6xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
746233611703.dkr.e <u>0.15.0</u> central-1.amazonaws.com/ sagemaker-neo- tensorflow:<tag>		inference	inf	py3

### Tensorflow Ray (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='ray-tensorflow', region='eu-
central-1', version='0.8.5', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
462105765813.dkr.e <u>0.8.2</u> - central-1.amazonaws.com/ sagemaker-rl-ray- container:ray-0.8.2- tf-<tag>		training	CPU, GPU	py36
462105765813.dkr.e <u>0.8.5</u> - central-1.amazonaws.com/ sagemaker-rl-ray- container:ray-0.8.5- tf-<tag>		training	CPU, GPU	py36
520713654638.dkr.e <u>0.5.0</u> - central-1.amazonaws.com/ sagemaker-rl- tensorflow:ray0.5- <tag>		training	CPU, GPU	py3
520713654638.dkr.e <u>0.5.3</u> - central-1.amazonaws.com/ sagemaker-rl- tensorflow:ray0.5.3- <tag>		training	CPU, GPU	py3
520713654638.dkr.e <u>0.6.0</u> - central-1.amazonaws.com/ sagemaker-rl- tensorflow:ray0.6- <tag>		training	CPU, GPU	py3
520713654638.dkr.e <u>0.6.5</u> - central-1.amazonaws.com/ sagemaker-rl- tensorflow:ray0.6.5- <tag>		training	CPU, GPU	py3

## VW (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='vw', region='eu-central-1', version='8.7.0', image_scope='training')
```

Registry path	Version	Job types (image scope)		
462105765813.dkr.ecr.eu-8.7.0 central-1.amazonaws.com/ sagemaker-rl-vw- container:vw-8.7.0- <span style="color: red;">&lt;tag&gt;</span>		training		

## XGBoost (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='xgboost', region='eu-central-1', version='1.2-1')
```

Registry path	Version	Job types (image scope)		
492215442770.dkr.ecr.eu-0.90-1 central-1.amazonaws.com/ sagemaker- xgboost:<tag>		inference, training		
492215442770.dkr.ecr.eu-0.90-2 central-1.amazonaws.com/ sagemaker- xgboost:<tag>		inference, training		
492215442770.dkr.ecr.eu-1.0-1 central-1.amazonaws.com/ sagemaker- xgboost:<tag>		inference, training		
492215442770.dkr.ecr.eu-1.2-1 central-1.amazonaws.com/ sagemaker- xgboost:<tag>		inference, training		
492215442770.dkr.ecr.eu-1.2-2 central-1.amazonaws.com/ sagemaker- xgboost:<tag>		inference, training		
492215442770.dkr.ecr.eu-1.3-1 central-1.amazonaws.com/ sagemaker- xgboost:<tag>		inference, training		

Registry path	Version	Job types (image scope)		
813361260812.dkr.ecr.eu-1 central-1.amazonaws.com/ xgboost:<tag>		inference, training		

## Docker Registry Paths and Example Code for Europe (Ireland) (eu-west-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

### Topics

- [BlazingText \(algorithm\) \(p. 1139\)](#)
- [Chainer \(DLC\) \(p. 1139\)](#)

### [BlazingText \(algorithm\)](#)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='blazingtext',region='eu-west-1')
```

Registry path	Version	Job types (image scope)		
685385470294.dkr.ecr.eu-1 west-1.amazonaws.com/ blazingtext:<tag>		inference, training		

### [Chainer \(DLC\)](#)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='chainer',region='eu-
west-1',version='5.0.0',py_version='py3',image_scope='inference',instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
520713654638.dkr.ecr.eu-1 west-1.amazonaws.com/ sagemaker- chainer:<tag>		inference, training	CPU, GPU	py2, py3
520713654638.dkr.ecr.eu-1 west-1.amazonaws.com/ sagemaker- chainer:<tag>		inference, training	CPU, GPU	py2, py3
520713654638.dkr.ecr.eu-1 west-1.amazonaws.com/ sagemaker- chainer:<tag>		inference, training	CPU, GPU	py2, py3

### [Clarify \(algorithm\)](#)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='clarify',region='eu-west-1',version='1.0',image_scope='processing')
```

Registry path	Version	Job types (image scope)		
131013547314.dkr.ecr.eu-west-1.amazonaws.com/sagemaker-clarify-processing:<tag>		processing		

### Data Wrangler (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='data-wrangler',region='eu-west-1')
```

Registry path	Version	Job types (image scope)		
245179582081.dkr.ecr.eu-west-1.amazonaws.com/sagemaker-data-wrangler-container:<tag>		processing		

### Debugger (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='debugger',region='eu-west-1')
```

Registry path	Version	Job types (image scope)		
929884845733.dkr.ecr.eu-west-1.amazonaws.com/sagemaker-debugger-rules:<tag>	latest	debugger		

### DeepAR Forecasting (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='forecasting-deepar',region='eu-west-1')
```

Registry path	Version	Job types (image scope)		
224300973850.dkr.ecr.eu-1 west-1.amazonaws.com/ forecasting- deepar:<tag>		inference, training		

### Factorization Machines (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='factorization-machines',region='eu-west-1')
```

Registry path	Version	Job types (image scope)		
438346466558.dkr.ecr.eu-1 west-1.amazonaws.com/ factorization- machines:<tag>		inference, training		

### Hugging Face (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='huggingface',region='eu-west-1',version='4.4.2',image_scope='training',base_framework_version='tensorflow2.4.1')
```

Registry path	Version	Job types (image scope)		
763104351884.dkr.ecr.eu-4.4.2 west-1.amazonaws.com/ huggingface-pytorch- training:<tag>		training		
763104351884.dkr.ecr.eu-4.5.0 west-1.amazonaws.com/ huggingface-pytorch- training:<tag>		training		
763104351884.dkr.ecr.eu-4.4.2 west-1.amazonaws.com/ huggingface- tensorflow- training:<tag>		training		
763104351884.dkr.ecr.eu-4.5.0 west-1.amazonaws.com/ huggingface-		training		

Registry path	Version	Job types (image scope)		
tensorflow-training:<tag>				

### IP Insights (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='ipinsights',region='eu-west-1')
```

Registry path	Version	Job types (image scope)		
438346466558.dkr.ecr.eu-west-1.amazonaws.com/ipinsights:<tag>		inference, training		

### Image classification (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='image-classification',region='eu-west-1')
```

Registry path	Version	Job types (image scope)		
685385470294.dkr.ecr.eu-west-1.amazonaws.com/image-classification:<tag>		inference, training		

### Inferentia MXNet (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='inferentia-mxnet',region='eu-west-1',version='1.5.1',instance_type='ml.inf1.6xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
802834080501.dkr.ecr.eu-west-1.amazonaws.com/sagemaker-neo-mxnet:<tag>		inference	inf	py3

## Inferentia PyTorch (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='inferentia-pytorch',region='eu-west-1',version='1.5.1',py_version='py3')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
802834080501.dkr.ecr.eu-west-1.amazonaws.com/sagemaker-neo-pytorch:<tag>		inference	inf	py3

## K-Means (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='kmeans',region='eu-west-1')
```

Registry path	Version	Job types (image scope)		
438346466558.dkr.ecr.eu-west-1.amazonaws.com/kmeans:<tag>		inference, training		

## KNN (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='knn',region='eu-west-1')
```

Registry path	Version	Job types (image scope)		
438346466558.dkr.ecr.eu-west-1.amazonaws.com/knn:<tag>		inference, training		

## LDA (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='lda',region='eu-west-1')
```

Registry path	Version	Job types (image scope)		
999678624901.dkr.ecr.eu-west-1.amazonaws.com/lda:<tag>		inference, training		

### Linear Learner (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='linear-learner', region='eu-west-1')
```

Registry path	Version	Job types (image scope)		
438346466558.dkr.ecr.eu-west-1.amazonaws.com/linear-learner:<tag>		inference, training		

### MXNet (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='mxnet', region='eu-west-1', version='1.4.1', py_version='py3', image_scope='inference',
 instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
520713654638.dkr.ecr.eu-west-1.amazonaws.com/sagemaker-mxnet-eia:<tag>	edr.3.0-	eia	CPU	py2, py3
520713654638.dkr.ecr.eu-west-1.amazonaws.com/sagemaker-mxnet-serving-eia:<tag>	edr.4.0-	eia	CPU	py2, py3
520713654638.dkr.ecr.eu-west-1.amazonaws.com/sagemaker-mxnet-serving:<tag>	edr.4.0-	inference	CPU, GPU	py2, py3
520713654638.dkr.ecr.eu-west-1.amazonaws.com/sagemaker-mxnet-serving:<tag>	edr.4.1-	inference	CPU, GPU	py2

Registry path	Version	Job types (image scope)	Processor types	Python versions
520713654638.dkr.e0. <del>12</del> .1-west-1.amazonaws.com/sagemaker-mxnet:<tag>		inference	CPU, GPU	py2, py3
520713654638.dkr.e0. <del>12</del> .1-west-1.amazonaws.com/sagemaker-mxnet:<tag>		training	CPU, GPU	py2, py3
520713654638.dkr.edr.00-west-1.amazonaws.com/sagemaker-mxnet:<tag>		inference	CPU, GPU	py2, py3
520713654638.dkr.edr.00-west-1.amazonaws.com/sagemaker-mxnet:<tag>		training	CPU, GPU	py2, py3
520713654638.dkr.edr.10-west-1.amazonaws.com/sagemaker-mxnet:<tag>		inference	CPU, GPU	py2, py3
520713654638.dkr.edr.10-west-1.amazonaws.com/sagemaker-mxnet:<tag>		training	CPU, GPU	py2, py3
520713654638.dkr.edr.20-west-1.amazonaws.com/sagemaker-mxnet:<tag>		inference	CPU, GPU	py2, py3
520713654638.dkr.edr.20-west-1.amazonaws.com/sagemaker-mxnet:<tag>		training	CPU, GPU	py2, py3
520713654638.dkr.edr.30-west-1.amazonaws.com/sagemaker-mxnet:<tag>		inference	CPU, GPU	py2, py3
520713654638.dkr.edr.30-west-1.amazonaws.com/sagemaker-mxnet:<tag>		training	CPU, GPU	py2, py3
520713654638.dkr.edr.40-west-1.amazonaws.com/sagemaker-mxnet:<tag>		training	CPU, GPU	py2, py3

Registry path	Version	Job types (image scope)	Processor types	Python versions
520713654638.dkr.ecr.us-west-1.amazonaws.com/sagemaker-mxnet:<tag>		training	CPU, GPU	py2
763104351884.dkr.ecr.us-west-1.amazonaws.com/mxnet-inference-eia:<tag>		eia	CPU	py2, py3
763104351884.dkr.ecr.us-west-1.amazonaws.com/mxnet-inference-eia:<tag>		eia	CPU	py2, py3
763104351884.dkr.ecr.us-west-1.amazonaws.com/mxnet-inference-eia:<tag>		eia	CPU	py3
763104351884.dkr.ecr.us-west-1.amazonaws.com/mxnet-inference:<tag>		inference	CPU, GPU	py3
763104351884.dkr.ecr.us-west-1.amazonaws.com/mxnet-inference:<tag>		inference	CPU, GPU	py2, py3
763104351884.dkr.ecr.us-west-1.amazonaws.com/mxnet-inference:<tag>		inference	CPU, GPU	py3
763104351884.dkr.ecr.us-west-1.amazonaws.com/mxnet-inference:<tag>		inference	CPU, GPU	py37
763104351884.dkr.ecr.us-west-1.amazonaws.com/mxnet-training:<tag>		training	CPU, GPU	py3
763104351884.dkr.ecr.us-west-1.amazonaws.com/mxnet-training:<tag>		training	CPU, GPU	py2, py3
763104351884.dkr.ecr.us-west-1.amazonaws.com/mxnet-training:<tag>		training	CPU, GPU	py3

Registry path	Version	Job types (image scope)	Processor types	Python versions
763104351884.dkr.ecr.eu-west-1.amazonaws.com/mxnet-training:<tag>		training	CPU, GPU	py37

### MXNet Coach (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='coach-mxnet', region='eu-west-1', version='0.11', py_version='py3', image_scope='training', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
520713654638.dkr.ecr.eu-west-1.amazonaws.com/sagemaker-rl-mxnet:coach0.11-<tag>		training	CPU, GPU	py3
520713654638.dkr.ecr.eu-west-1.amazonaws.com/sagemaker-rl-mxnet:coach0.11.0-<tag>		training	CPU, GPU	py3

### Model Monitor (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='model-monitor', region='eu-west-1')
```

Registry path	Version	Job types (image scope)		
468650794304.dkr.ecr.eu-west-1.amazonaws.com/sagemaker-model-monitor-analyzer:<tag>		monitoring		

### NTM (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
```

```
image_uris.retrieve(framework='ntm', region='eu-west-1')
```

Registry path	Version	Job types (image scope)		
438346466558.dkr.ecr.eu-west-1.amazonaws.com/ntm:<tag>		inference, training		

### Neo Image Classification (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='image-classification-neo', region='eu-west-1')
```

Registry path	Version	Job types (image scope)		
802834080501.dkr.ecr.eu-west-1.amazonaws.com/image-classification-neo:<tag>	latest	inference		

### Neo MXNet (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='neo-mxnet', region='eu-west-1', version='1.8', py_version='py3', image_scope='inference',
 instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
802834080501.dkr.ecr.eu-west-1.amazonaws.com/sagemaker-inference-mxnet:<tag>		inference	CPU, GPU	py3

### Neo PyTorch (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='neo-pytorch', region='eu-west-1', version='1.6', image_scope='inference', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
802834080501.dkr.ecr.eu-west-1.amazonaws.com/sagemaker-inference-pytorch:<tag>		inference	CPU, GPU	py3
802834080501.dkr.ecr.eu-west-1.amazonaws.com/sagemaker-inference-pytorch:<tag>		inference	CPU, GPU	py3
802834080501.dkr.ecr.eu-west-1.amazonaws.com/sagemaker-inference-pytorch:<tag>		inference	CPU, GPU	py3

### Neo Tensorflow (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='neo-tensorflow', region='eu-west-1', version='1.15.3', py_version='py3', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
802834080501.dkr.ecr.eu-west-1.amazonaws.com/sagemaker-inference-tensorflow:<tag>	1.15.3	inference	CPU, GPU	py3

### Neo XGBoost (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='xgboost-neo', region='eu-west-1')
```

Registry path	Version	Job types (image scope)		
802834080501.dkr.ecr.eu-west-1.amazonaws.com/xgboost-neo:<tag>	latest	inference		

## Object Detection (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='object-detection',region='eu-west-1')
```

Registry path	Version	Job types (image scope)		
685385470294.dkr.ecr.eu-1 west-1.amazonaws.com/ object-detection:<tag>		inference, training		

## Object2Vec (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='object2vec',region='eu-west-1')
```

Registry path	Version	Job types (image scope)		
438346466558.dkr.ecr.eu-1 west-1.amazonaws.com/ object2vec:<tag>		inference, training		

## PCA (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='pca',region='eu-west-1')
```

Registry path	Version	Job types (image scope)		
438346466558.dkr.ecr.eu-1 west-1.amazonaws.com/ pca:<tag>		inference, training		

## PyTorch (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='pytorch',region='eu-
west-1',version='1.8.0',py_version='py3',image_scope='inference',
instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
520713654638.dkr.e0.40-west-1.amazonaws.com/sagemaker-pytorch:<tag>		inference	CPU, GPU	py2, py3
520713654638.dkr.e0.40-west-1.amazonaws.com/sagemaker-pytorch:<tag>		training	CPU, GPU	py2, py3
520713654638.dkr.edr.0.0-west-1.amazonaws.com/sagemaker-pytorch:<tag>		inference	CPU, GPU	py2, py3
520713654638.dkr.edr.0.0-west-1.amazonaws.com/sagemaker-pytorch:<tag>		training	CPU, GPU	py2, py3
520713654638.dkr.edr.1.0-west-1.amazonaws.com/sagemaker-pytorch:<tag>		inference	CPU, GPU	py2, py3
520713654638.dkr.edr.1.0-west-1.amazonaws.com/sagemaker-pytorch:<tag>		training	CPU, GPU	py2, py3
763104351884.dkr.edr.3.1-west-1.amazonaws.com/pytorch-inference-eia:<tag>		eia	CPU	py3
763104351884.dkr.edr.2.0-west-1.amazonaws.com/pytorch-inference:<tag>		inference	CPU, GPU	py2, py3

### Random Cut Forest (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='randomcutforest', region='eu-west-1')
```

Registry path	Version	Job types (image scope)		
438346466558.dkr.ecr.eu-west-1.amazonaws.com/randomcutforest:<tag>		inference, training		

### Ray PyTorch (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='ray-pytorch', region='eu-west-1', version='0.8.5', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
462105765813.dkr.ecr.eu-west-1.amazonaws.com/sagemaker-rl-ray-container:ray-0.8.5-torch-<tag>		training	CPU, GPU	py36

### Scikit-learn (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='sklearn', region='eu-west-1', version='0.23-1', image_scope='inference')
```

Registry path	Version	Job types (image scope)		
141502667606.dkr.ecr.eu-west-1.amazonaws.com/	0.20.0	inference, training		

Registry path	Version	Job types (image scope)		
sagemaker-scikit-learn:<tag>				
141502667606.dkr.ecr.eu-0.23-1 west-1.amazonaws.com/ sagemaker-scikit-learn:<tag>		inference, training		

### Semantic Segmentation (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='semantic-segmentation',region='eu-west-1')
```

Registry path	Version	Job types (image scope)		
685385470294.dkr.ecr.eu-1 west-1.amazonaws.com/ semantic-segmentation:<tag>		inference, training		

### Seq2Seq (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='seq2seq',region='eu-west-1')
```

Registry path	Version	Job types (image scope)		
685385470294.dkr.ecr.eu-1 west-1.amazonaws.com/ seq2seq:<tag>		inference, training		

### Spark (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='spark',region='eu-west-1',version='3.0',image_scope='processing')
```

Registry path	Version	Job types (image scope)		
571004829621.dkr.ecr.eu-2.4 west-1.amazonaws.com/		processing		

Registry path	Version	Job types (image scope)		
sagemaker-spark-processing:<tag>				
571004829621.dkr.ecr.eu-3.0 west-1.amazonaws.com/ sagemaker-spark-processing:<tag>		processing		

## SparkML Serving (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='sparkml-serving', region='eu-west-1', version='2.4')
```

Registry path	Version	Job types (image scope)		
141502667606.dkr.ecr.eu-2.2 west-1.amazonaws.com/ sagemaker-sparkml-serving:<tag>		inference		
141502667606.dkr.ecr.eu-2.4 west-1.amazonaws.com/ sagemaker-sparkml-serving:<tag>		inference		

## Tensorflow (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='tensorflow', region='eu-west-1', version='1.12.0', image_scope='inference', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions

### Tensorflow Coach (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='coach-tensorflow',region='eu-west-1',version='1.0.0',image_scope='training',instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
462105765813.dkr.e <u>0.0</u> -west-1.amazonaws.com/sagemaker-		training	CPU, GPU	py3

Registry path	Version	Job types (image scope)	Processor types	Python versions
rl-coach-container:coach-1.0.0-tf-<tag>				
520713654638.dkr.e0.10-west-1.amazonaws.com/sagemaker-rl-tensorflow:coach0.10-<tag>		training	CPU, GPU	py3
520713654638.dkr.e0.10.1-west-1.amazonaws.com/sagemaker-rl-tensorflow:coach0.10.1-<tag>		training	CPU, GPU	py3
520713654638.dkr.e0.11-west-1.amazonaws.com/sagemaker-rl-tensorflow:coach0.11-<tag>		training	CPU, GPU	py3
520713654638.dkr.e0.11.0-west-1.amazonaws.com/sagemaker-rl-tensorflow:coach0.11.0-<tag>		training	CPU, GPU	py3
520713654638.dkr.e0.11.1-west-1.amazonaws.com/sagemaker-rl-tensorflow:coach0.11.1-<tag>		training	CPU, GPU	py3

## Tensorflow Inferentia (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='inferentia-tensorflow',region='eu-west-1',version='1.15.0',instance_type='ml.inf1.6xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
802834080501.dkr.e0.15.0-west-1.amazonaws.com/sagemaker-neo-tensorflow:<tag>		inference	inf	py3

## Tensorflow Ray (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='ray-tensorflow', region='eu-west-1', version='0.8.5', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
462105765813.dkr.e0.8.2-west-1.amazonaws.com/sagemaker-rl-ray-container:ray-0.8.2-tf-<tag>		training	CPU, GPU	py36
462105765813.dkr.e0.8.5-west-1.amazonaws.com/sagemaker-rl-ray-container:ray-0.8.5-tf-<tag>		training	CPU, GPU	py36
520713654638.dkr.e0.5.eu-west-1.amazonaws.com/sagemaker-rl-tensorflow:ray0.5-<tag>		training	CPU, GPU	py3
520713654638.dkr.e0.5.3-west-1.amazonaws.com/sagemaker-rl-tensorflow:ray0.5.3-<tag>		training	CPU, GPU	py3
520713654638.dkr.e0.6.eu-west-1.amazonaws.com/sagemaker-rl-tensorflow:ray0.6-<tag>		training	CPU, GPU	py3
520713654638.dkr.e0.6.5-west-1.amazonaws.com/sagemaker-rl-tensorflow:ray0.6.5-<tag>		training	CPU, GPU	py3

## VW (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='vw', region='eu-west-1', version='8.7.0', image_scope='training')
```

Registry path	Version	Job types (image scope)		
462105765813.dkr.ecr.eu-west-1.amazonaws.com/		training		

Registry path	Version	Job types (image scope)		
sagemaker-rl-vw-container:vw-8.7.0-<tag>				

### XGBoost (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='xgboost',region='eu-west-1',version='1.2-1')
```

Registry path	Version	Job types (image scope)		
141502667606.dkr.ecr.eu-west-1.amazonaws.com/sagemaker-xgboost:<tag>	0.90-1	inference, training		
141502667606.dkr.ecr.eu-west-1.amazonaws.com/sagemaker-xgboost:<tag>	0.90-2	inference, training		
141502667606.dkr.ecr.eu-west-1.amazonaws.com/sagemaker-xgboost:<tag>	1.0-1	inference, training		
141502667606.dkr.ecr.eu-west-1.amazonaws.com/sagemaker-xgboost:<tag>	1.2-1	inference, training		
141502667606.dkr.ecr.eu-west-1.amazonaws.com/sagemaker-xgboost:<tag>	1.2-2	inference, training		
141502667606.dkr.ecr.eu-west-1.amazonaws.com/sagemaker-xgboost:<tag>	1.3-1	inference, training		
685385470294.dkr.ecr.eu-west-1.amazonaws.com/xgboost:<tag>	1	inference, training		

### Docker Registry Paths and Example Code for Europe (London) (eu-west-2)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

## Topics

## BlazingText (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='blazingtext', region='eu-west-2')
```

Registry path	Version	Job types (image scope)		
644912444149.dkr.ecr.eu-1 west-2.amazonaws.com/ blazingtext:<tag>		inference, training		

## Chainer (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='chainer', region='eu-west-2', version='5.0.0', py_version='py3', image_scope='inference', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
520713654638.dkr.e <u>4.0.0</u> - west-2.amazonaws.com/ sagemaker- chainer:<tag>		inference, training	CPU, GPU	py2, py3
520713654638.dkr.e <u>4.1.0</u> - west-2.amazonaws.com/ sagemaker- chainer:<tag>		inference, training	CPU, GPU	py2, py3
520713654638.dkr.e <u>5.0.0</u> - west-2.amazonaws.com/ sagemaker- chainer:<tag>		inference, training	CPU, GPU	py2, py3

## Clarify (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='clarify', region='eu-west-2', version='1.0', image_scope='processing')
```

Registry path	Version	Job types (image scope)		
440796970383.dkr.ecr.eu-1.0 west-2.amazonaws.com/		processing		

Registry path	Version	Job types (image scope)		
sagemaker-clarify-processing:<tag>				

### Data Wrangler (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='data-wrangler', region='eu-west-2')
```

Registry path	Version	Job types (image scope)		
894491911112.dkr.ecr.eu-1.x west-2.amazonaws.com/ sagemaker- data-wrangler- container:<tag>		processing		

### Debugger (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='debugger', region='eu-west-2')
```

Registry path	Version	Job types (image scope)		
250201462417.dkr.ecr.eu-latest west-2.amazonaws.com/ sagemaker-debugger- rules:<tag>		debugger		

### DeepAR Forecasting (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='forecasting-deepar', region='eu-west-2')
```

Registry path	Version	Job types (image scope)		
644912444149.dkr.ecr.eu-1 west-2.amazonaws.com/		inference, training		

Registry path	Version	Job types (image scope)		
forecasting-deepar:<tag>				

## Factorization Machines (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='factorization-machines', region='eu-west-2')
```

Registry path	Version	Job types (image scope)		
644912444149.dkr.ecr.eu-1 west-2.amazonaws.com/ factorization- machines:<tag>		inference, training		

## Hugging Face (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='huggingface', region='eu-west-2', version='4.4.2', image_scope='training', base_framework_version='tensorflow2.4.1')
```

Registry path	Version	Job types (image scope)		
763104351884.dkr.ecr.eu-4.4.2 west-2.amazonaws.com/ huggingface-pytorch- training:<tag>		training		
763104351884.dkr.ecr.eu-4.5.0 west-2.amazonaws.com/ huggingface-pytorch- training:<tag>		training		
763104351884.dkr.ecr.eu-4.4.2 west-2.amazonaws.com/ huggingface- tensorflow- training:<tag>		training		
763104351884.dkr.ecr.eu-4.5.0 west-2.amazonaws.com/ huggingface- tensorflow- training:<tag>		training		

## IP Insights (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='ipinsights',region='eu-west-2')
```

Registry path	Version	Job types (image scope)		
644912444149.dkr.ecr.eu-1 west-2.amazonaws.com/ ipinsights:<tag>		inference, training		

## Image classification (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='image-classification',region='eu-west-2')
```

Registry path	Version	Job types (image scope)		
644912444149.dkr.ecr.eu-1 west-2.amazonaws.com/ image- classification:<tag>		inference, training		

## Inferentia MXNet (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='inferentia-mxnet',region='eu-  
west-2',version='1.5.1',instance_type='ml.inf1.6xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
205493899709.dkr.ecr.eu-1 west-2.amazonaws.com/ sagemaker-neo- mxnet:<tag>		inference	inf	py3

## Inferentia PyTorch (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='inferentia-pytorch',region='eu-  
west-2',version='1.5.1',py_version='py3')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
205493899709.dkr.ecr.eu-1-west-2.amazonaws.com/ sagemaker-neo-pytorch:<tag>		inference	inf	py3

### K-Means (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='kmeans', region='eu-west-2')
```

Registry path	Version	Job types (image scope)		
644912444149.dkr.ecr.eu-1-west-2.amazonaws.com/ kmeans:<tag>		inference, training		

### KNN (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='knn', region='eu-west-2')
```

Registry path	Version	Job types (image scope)		
644912444149.dkr.ecr.eu-1-west-2.amazonaws.com/ knn:<tag>		inference, training		

### LDA (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='lda', region='eu-west-2')
```

Registry path	Version	Job types (image scope)		
644912444149.dkr.ecr.eu-1-west-2.amazonaws.com/ lda:<tag>		inference, training		

## Linear Learner (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='linear-learner', region='eu-west-2')
```

Registry path	Version	Job types (image scope)		
644912444149.dkr.ecr.eu-west-2.amazonaws.com/linear-learner:<tag>		inference, training		

## MXNet (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='mxnet', region='eu-west-2', version='1.4.1', py_version='py3', image_scope='inference',
 instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
520713654638.dkr.edr.10-west-2.amazonaws.com/sagemaker-mxnet-eia:<tag>		eia	CPU	py2, py3

## MXNet Coach (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
```

```
image_uris.retrieve(framework='coach-mxnet',region='eu-west-2',version='0.11',py_version='py3',image_scope='training',instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
520713654638.dkr.e0.eu-west-2.amazonaws.com/sagemaker-rl-mxnet:coach0.11-<tag>		training	CPU, GPU	py3
520713654638.dkr.e0.eu-west-2.amazonaws.com/sagemaker-rl-mxnet:coach0.11.0-<tag>		training	CPU, GPU	py3

### Model Monitor (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='model-monitor',region='eu-west-2')
```

Registry path	Version	Job types (image scope)		
749857270468.dkr.ecr.eu-west-2.amazonaws.com/sagemaker-model-monitor-analyzer:<tag>		monitoring		

### NTM (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='ntm',region='eu-west-2')
```

Registry path	Version	Job types (image scope)		
644912444149.dkr.ecr.eu-west-2.amazonaws.com/ntm:<tag>		inference, training		

### Neo Image Classification (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
```

```
image_uris.retrieve(framework='image-classification-neo',region='eu-west-2')
```

Registry path	Version	Job types (image scope)		
205493899709.dkr.ecr.eu-west-2.amazonaws.com/image-classification-neo:<tag>	latest	inference		

### Neo MXNet (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='neo-mxnet',region='eu-west-2',version='1.8',py_version='py3',image_scope='inference',
instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
205493899709.dkr.ecr.eu-west-2.amazonaws.com/sagemaker-inference-mxnet:<tag>		inference	CPU, GPU	py3

### Neo PyTorch (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='neo-pytorch',region='eu-west-2',version='1.6',image_scope='inference',instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
205493899709.dkr.ecr.eu-west-2.amazonaws.com/sagemaker-inference-pytorch:<tag>		inference	CPU, GPU	py3
205493899709.dkr.ecr.eu-west-2.amazonaws.com/sagemaker-inference-pytorch:<tag>		inference	CPU, GPU	py3
205493899709.dkr.ecr.eu-west-2.amazonaws.com/		inference	CPU, GPU	py3

Registry path	Version	Job types (image scope)	Processor types	Python versions
sagemaker-inference-pytorch:<tag>				

### Neo Tensorflow (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='neo-tensorflow', region='eu-west-2', version='1.15.3', py_version='py3', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
205493899709.dkr.ecr.eu-west-2.amazonaws.com/sagemaker-inference-tensorflow:<tag>	1.15.3	inference	CPU, GPU	py3

### Neo XGBoost (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='xgboost-neo', region='eu-west-2')
```

Registry path	Version	Job types (image scope)		
205493899709.dkr.ecr.eu-west-2.amazonaws.com/xgboost-neo:<tag>	latest	inference		

### Object Detection (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='object-detection', region='eu-west-2')
```

Registry path	Version	Job types (image scope)		
644912444149.dkr.ecr.eu-west-2.amazonaws.com/object-detection:<tag>	1	inference, training		

## Object2Vec (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='object2vec',region='eu-west-2')
```

Registry path	Version	Job types (image scope)		
644912444149.dkr.ecr.eu-1 west-2.amazonaws.com/ object2vec:<tag>		inference, training		

## PCA (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='pca',region='eu-west-2')
```

Registry path	Version	Job types (image scope)		
644912444149.dkr.ecr.eu-1 west-2.amazonaws.com/ pca:<tag>		inference, training		

## PyTorch (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='pytorch',region='eu-
west-2',version='1.8.0',py_version='py3',image_scope='inference',
instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
520713654638.dkr.e0.40- west-2.amazonaws.com/ sagemaker- pytorch:<tag>		inference	CPU, GPU	py2, py3
520713654638.dkr.e0.40- west-2.amazonaws.com/ sagemaker- pytorch:<tag>		training	CPU, GPU	py2, py3
520713654638.dkr.e0.40- west-2.amazonaws.com/ sagemaker- pytorch:<tag>		inference	CPU, GPU	py2, py3

Registry path	Version	Job types (image scope)	Processor types	Python versions
520713654638.dkr.edr. <b>00</b> -west-2.amazonaws.com/sagemaker-pytorch:<tag>		training	CPU, GPU	py2, py3
520713654638.dkr.edr. <b>10</b> -west-2.amazonaws.com/sagemaker-pytorch:<tag>		inference	CPU, GPU	py2, py3
520713654638.dkr.edr. <b>10</b> -west-2.amazonaws.com/sagemaker-pytorch:<tag>		training	CPU, GPU	py2, py3
763104351884.dkr.edr. <b>01</b> -west-2.amazonaws.com/pytorch-inference-eia:<tag>		eia	CPU	py3
763104351884.dkr.edr. <b>20</b> -west-2.amazonaws.com/pytorch-inference:<tag>		inference	CPU, GPU	py2, py3
763104351884.dkr.edr. <b>30</b> -west-2.amazonaws.com/pytorch-inference:<tag>		inference	CPU, GPU	py2, py3
763104351884.dkr.edr. <b>40</b> -west-2.amazonaws.com/pytorch-inference:<tag>		inference	CPU, GPU	py3
763104351884.dkr.edr. <b>50</b> -west-2.amazonaws.com/pytorch-inference:<tag>		inference	CPU, GPU	py3
763104351884.dkr.edr. <b>60</b> -west-2.amazonaws.com/pytorch-inference:<tag>		inference	CPU, GPU	py3, py36
763104351884.dkr.edr. <b>70</b> -west-2.amazonaws.com/pytorch-inference:<tag>		inference	CPU, GPU	py3, py36
763104351884.dkr.edr. <b>80</b> -west-2.amazonaws.com/pytorch-inference:<tag>		inference	CPU, GPU	py3, py36

Registry path	Version	Job types (image scope)	Processor types	Python versions
763104351884.dkr.edr. <del>81</del> -west-2.amazonaws.com/pytorch-inference:<tag>		inference	CPU, GPU	py3, py36
763104351884.dkr.edr. <del>20</del> -west-2.amazonaws.com/pytorch-training:<tag>		training	CPU, GPU	py2, py3
763104351884.dkr.edr. <del>51</del> -west-2.amazonaws.com/pytorch-training:<tag>		training	CPU, GPU	py2, py3
763104351884.dkr.edr. <del>40</del> -west-2.amazonaws.com/pytorch-training:<tag>		training	CPU, GPU	py2, py3
763104351884.dkr.edr. <del>50</del> -west-2.amazonaws.com/pytorch-training:<tag>		training	CPU, GPU	py3
763104351884.dkr.edr. <del>60</del> -west-2.amazonaws.com/pytorch-training:<tag>		training	CPU, GPU	py3, py36
763104351884.dkr.edr. <del>71</del> -west-2.amazonaws.com/pytorch-training:<tag>		training	CPU, GPU	py3, py36
763104351884.dkr.edr. <del>80</del> -west-2.amazonaws.com/pytorch-training:<tag>		training	CPU, GPU	py3, py36
763104351884.dkr.edr. <del>81</del> -west-2.amazonaws.com/pytorch-training:<tag>		training	CPU, GPU	py3, py36

### Random Cut Forest (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='randomcutforest', region='eu-west-2')
```

Registry path	Version	Job types (image scope)		
644912444149.dkr.ecr.eu-1 west-2.amazonaws.com/ randomcutforest:<tag>		inference, training		

### Ray PyTorch (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='ray-pytorch', region='eu-west-2', version='0.8.5', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
462105765813.dkr.e0.8.5- west-2.amazonaws.com/ sagemaker-rl-ray- container:ray-0.8.5- torch-<tag>	0.8.5-	training	CPU, GPU	py36

### Scikit-learn (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='sklearn', region='eu-west-2', version='0.23-1', image_scope='inference')
```

Registry path	Version	Job types (image scope)		
764974769150.dkr.ecr.eu-0.20.0 west-2.amazonaws.com/ sagemaker-scikit- learn:<tag>	-0.20.0	inference, training		
764974769150.dkr.ecr.eu-0.23-1 west-2.amazonaws.com/ sagemaker-scikit- learn:<tag>	-0.23-1	inference, training		

### Semantic Segmentation (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
```

```
image_uris.retrieve(framework='semantic-segmentation',region='eu-west-2')
```

Registry path	Version	Job types (image scope)		
644912444149.dkr.ecr.eu-1 west-2.amazonaws.com/ semantic- segmentation:<tag>		inference, training		

## Seq2Seq (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='seq2seq',region='eu-west-2')
```

Registry path	Version	Job types (image scope)		
644912444149.dkr.ecr.eu-1 west-2.amazonaws.com/ seq2seq:<tag>		inference, training		

## Spark (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='spark',region='eu-  
west-2',version='3.0',image_scope='processing')
```

Registry path	Version	Job types (image scope)		
836651553127.dkr.ecr.eu-2.4 west-2.amazonaws.com/ sagemaker-spark- processing:<tag>		processing		
836651553127.dkr.ecr.eu-3.0 west-2.amazonaws.com/ sagemaker-spark- processing:<tag>		processing		

## SparkML Serving (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='sparkml-serving',region='eu-west-2',version='2.4')
```

Registry path	Version	Job types (image scope)		
764974769150.dkr.ecr.eu-2.2 west-2.amazonaws.com/ sagemaker-sparkml- serving:<tag>		inference		
764974769150.dkr.ecr.eu-2.4 west-2.amazonaws.com/ sagemaker-sparkml- serving:<tag>		inference		

### Tensorflow (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='tensorflow', region='eu-west-2', version='1.12.0', image_scope='inference', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions

### Tensorflow Coach (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='coach-tensorflow', region='eu-west-2', version='1.0.0', image_scope='training', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
462105765813.dkr.e <u>0.10</u> -west-2.amazonaws.com/sagemaker-rl-coach-container:coach-1.0.0-tf-<tag>		training	CPU, GPU	py3
520713654638.dkr.e <u>0.10</u> -west-2.amazonaws.com/sagemaker-rl-tensorflow:coach0.10-<tag>		training	CPU, GPU	py3
520713654638.dkr.e <u>0.10</u> .1-west-2.amazonaws.com/sagemaker-rl-tensorflow:coach0.10.1-<tag>		training	CPU, GPU	py3
520713654638.dkr.e <u>0.11</u> -west-2.amazonaws.com/sagemaker-rl-tensorflow:coach0.11-<tag>		training	CPU, GPU	py3
520713654638.dkr.e <u>0.11</u> .0-west-2.amazonaws.com/sagemaker-rl-		training	CPU, GPU	py3

Registry path	Version	Job types (image scope)	Processor types	Python versions
tensorflow:coach0.11.0-<tag>				
520713654638.dkr.e0.11.1-west-2.amazonaws.com/sagemaker-rl-tensorflow:coach0.11.1-<tag>		training	CPU, GPU	py3

## Tensorflow Inference (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='inferentia-tensorflow',region='eu-west-2',version='1.15.0',instance_type='ml.inf1.6xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
205493899709.dkr.e0.15.0-west-2.amazonaws.com/sagemaker-neo-tensorflow:<tag>		inference	inf	py3

## Tensorflow Ray (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='ray-tensorflow',region='eu-west-2',version='0.8.5',instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
462105765813.dkr.e0.8.2-west-2.amazonaws.com/sagemaker-rl-ray-container:ray-0.8.2-tf-<tag>		training	CPU, GPU	py36
462105765813.dkr.e0.8.5-west-2.amazonaws.com/sagemaker-rl-ray-container:ray-0.8.5-tf-<tag>		training	CPU, GPU	py36
520713654638.dkr.e0.5u-west-2.amazonaws.com/sagemaker-rl-		training	CPU, GPU	py3

Registry path	Version	Job types (image scope)	Processor types	Python versions
tensorflow:ray0.5-<tag>				
520713654638.dkr.e0.5.3-west-2.amazonaws.com/sagemaker-rl-tensorflow:ray0.5.3-<tag>		training	CPU, GPU	py3
520713654638.dkr.e0.6-eu-west-2.amazonaws.com/sagemaker-rl-tensorflow:ray0.6-<tag>		training	CPU, GPU	py3
520713654638.dkr.e0.6.5-west-2.amazonaws.com/sagemaker-rl-tensorflow:ray0.6.5-<tag>		training	CPU, GPU	py3

## VW (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='vw', region='eu-west-2', version='8.7.0', image_scope='training')
```

Registry path	Version	Job types (image scope)		
462105765813.dkr.ecr.eu-west-2.amazonaws.com/sagemaker-rl-vw-container:vw-8.7.0-<tag>	8.7.0	training		

## XGBoost (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='xgboost', region='eu-west-2', version='1.2-1')
```

Registry path	Version	Job types (image scope)		
644912444149.dkr.ecr.eu-west-2.amazonaws.com/xgboost:<tag>	1	inference, training		

Registry path	Version	Job types (image scope)		
764974769150.dkr.ecr.eu-west-2.amazonaws.com/sagemaker-xgboost:<tag>	0.90-1	inference, training		
764974769150.dkr.ecr.eu-west-2.amazonaws.com/sagemaker-xgboost:<tag>	0.90-2	inference, training		
764974769150.dkr.ecr.eu-west-2.amazonaws.com/sagemaker-xgboost:<tag>	1.0-1	inference, training		
764974769150.dkr.ecr.eu-west-2.amazonaws.com/sagemaker-xgboost:<tag>	1.2-1	inference, training		
764974769150.dkr.ecr.eu-west-2.amazonaws.com/sagemaker-xgboost:<tag>	1.2-2	inference, training		
764974769150.dkr.ecr.eu-west-2.amazonaws.com/sagemaker-xgboost:<tag>	1.3-1	inference, training		

### Docker Registry Paths and Example Code for Europe (Paris) (eu-west-3)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

#### Topics

### [BlazingText \(algorithm\)](#)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='blazingtext', region='eu-west-3')
```

Registry path	Version	Job types (image scope)		
749696950732.dkr.ecr.eu-west-3.amazonaws.com/blazingtext:<tag>		inference, training		

### [Chainer \(DLC\)](#)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
```

```
image_uris.retrieve(framework='chainer', region='eu-west-3', version='5.0.0', py_version='py3', image_scope='inference', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
520713654638.dkr.ecr.eu-west-3.amazonaws.com/sagemaker-chainer:<tag>	4.0.0	inference, training	CPU, GPU	py2, py3
520713654638.dkr.ecr.eu-west-3.amazonaws.com/sagemaker-chainer:<tag>	4.1.0	inference, training	CPU, GPU	py2, py3
520713654638.dkr.ecr.eu-west-3.amazonaws.com/sagemaker-chainer:<tag>	5.0.0	inference, training	CPU, GPU	py2, py3

### Clarify (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='clarify', region='eu-west-3', version='1.0', image_scope='processing')
```

Registry path	Version	Job types (image scope)		
341593696636.dkr.ecr.eu-west-3.amazonaws.com/sagemaker-clarify-processing:<tag>	1.0	processing		

### Data Wrangler (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='data-wrangler', region='eu-west-3')
```

Registry path	Version	Job types (image scope)		
807237891255.dkr.ecr.eu-west-3.amazonaws.com/sagemaker-data-wrangler-container:<tag>	1.x	processing		

## Debugger (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='debugger', region='eu-west-3')
```

Registry path	Version	Job types (image scope)		
447278800020.dkr.ecr.eu-west-3.amazonaws.com/sagemaker-debugger-rules:<tag>	latest	debugger		

## DeepAR Forecasting (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='forecasting-deepar', region='eu-west-3')
```

Registry path	Version	Job types (image scope)		
749696950732.dkr.ecr.eu-west-3.amazonaws.com/forecasting-deepar:<tag>	1	inference, training		

## Factorization Machines (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='factorization-machines', region='eu-west-3')
```

Registry path	Version	Job types (image scope)		
749696950732.dkr.ecr.eu-west-3.amazonaws.com/factorization-machines:<tag>	1	inference, training		

## Hugging Face (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='huggingface', region='eu-west-3', version='4.4.2', image_scope='training', base_framework_version='tensorflow2.4.1')
```

Registry path	Version	Job types (image scope)		
763104351884.dkr.ecr.eu-4.4.2 west-3.amazonaws.com/ huggingface-pytorch- training:<tag>		training		
763104351884.dkr.ecr.eu-4.5.0 west-3.amazonaws.com/ huggingface-pytorch- training:<tag>		training		
763104351884.dkr.ecr.eu-4.4.2 west-3.amazonaws.com/ huggingface- tensorflow- training:<tag>		training		
763104351884.dkr.ecr.eu-4.5.0 west-3.amazonaws.com/ huggingface- tensorflow- training:<tag>		training		

## IP Insights (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='ipinsights', region='eu-west-3')
```

Registry path	Version	Job types (image scope)		
749696950732.dkr.ecr.eu-1 west-3.amazonaws.com/ ipinsights:<tag>		inference, training		

## Image classification (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='image-classification', region='eu-west-3')
```

Registry path	Version	Job types (image scope)		
749696950732.dkr.ecr.eu-1 west-3.amazonaws.com/ image- classification:<tag>		inference, training		

## Inferentia MXNet (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='inferentia-mxnet',region='eu-west-3',version='1.5.1',instance_type='ml.inf1.6xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
254080097072.dkr.ecr.eu-west-3.amazonaws.com/sagemaker-neo-mxnet:<tag>		inference	inf	py3

## Inferentia PyTorch (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='inferentia-pytorch',region='eu-west-3',version='1.5.1',py_version='py3')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
254080097072.dkr.ecr.eu-west-3.amazonaws.com/sagemaker-neo-pytorch:<tag>		inference	inf	py3

## K-Means (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='kmeans',region='eu-west-3')
```

Registry path	Version	Job types (image scope)		
749696950732.dkr.ecr.eu-west-3.amazonaws.com/kmeans:<tag>		inference, training		

## KNN (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='knn',region='eu-west-3')
```

Registry path	Version	Job types (image scope)		
749696950732.dkr.ecr.eu-1 west-3.amazonaws.com/ knn:<tag>		inference, training		

### Linear Learner (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='linear-learner', region='eu-west-3')
```

Registry path	Version	Job types (image scope)		
749696950732.dkr.ecr.eu-1 west-3.amazonaws.com/ linear-learner:<tag>		inference, training		

### MXNet (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='mxnet', region='eu-west-3', version='1.4.1', py_version='py3', image_scope='inference',
 instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
520713654638.dkr.ecr.eu-1 west-3.amazonaws.com/ sagemaker-mxnet-eia:<tag>		eia	CPU	py2, py3

763104351884.dkr.ecr.eu-west-3.amazonaws.com/mxnet-training:<tag>		training	CPU, GPU	py37

### MXNet Coach (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='coach-mxnet', region='eu-west-3', version='0.11', py_version='py3', image_scope='training', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
520713654638.dkr.ecr.eu-west-3.amazonaws.com/sagemaker-rl-mxnet:coach0.11-<tag>		training	CPU, GPU	py3
520713654638.dkr.ecr.eu-west-3.amazonaws.com/sagemaker-rl-mxnet:coach0.11.0-<tag>		training	CPU, GPU	py3

### Model Monitor (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='model-monitor', region='eu-west-3')
```

Registry path	Version	Job types (image scope)		
680080141114.dkr.ecr.eu-west-3.amazonaws.com/sagemaker-model-monitor-analyzer:<tag>		monitoring		

### NTM (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
```

```
image_uris.retrieve(framework='ntm', region='eu-west-3')
```

Registry path	Version	Job types (image scope)		
749696950732.dkr.ecr.eu-west-3.amazonaws.com/ntm:<tag>		inference, training		

### Neo Image Classification (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='image-classification-neo', region='eu-west-3')
```

Registry path	Version	Job types (image scope)		
254080097072.dkr.ecr.eu-west-3.amazonaws.com/image-classification-neo:<tag>	latest	inference		

### Neo MXNet (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='neo-mxnet', region='eu-west-3', version='1.8', py_version='py3', image_scope='inference',
 instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
254080097072.dkr.ecr.eu-west-3.amazonaws.com/sagemaker-inference-mxnet:<tag>		inference	CPU, GPU	py3

### Neo PyTorch (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='neo-pytorch', region='eu-west-3', version='1.6', image_scope='inference', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
254080097072.dkr.ecr.eu-west-3.amazonaws.com/sagemaker-inference-pytorch:<tag>		inference	CPU, GPU	py3
254080097072.dkr.ecr.eu-west-3.amazonaws.com/sagemaker-inference-pytorch:<tag>		inference	CPU, GPU	py3
254080097072.dkr.ecr.eu-west-3.amazonaws.com/sagemaker-inference-pytorch:<tag>		inference	CPU, GPU	py3

### Neo Tensorflow (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='neo-tensorflow', region='eu-west-3', version='1.15.3', py_version='py3', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
254080097072.dkr.ecr.eu-west-3.amazonaws.com/sagemaker-inference-tensorflow:<tag>	1.15.3	inference	CPU, GPU	py3

### Neo XGBoost (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='xgboost-neo', region='eu-west-3')
```

Registry path	Version	Job types (image scope)		
254080097072.dkr.ecr.eu-west-3.amazonaws.com/xgboost-neo:<tag>	latest	inference		

## Object Detection (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='object-detection',region='eu-west-3')
```

Registry path	Version	Job types (image scope)		
749696950732.dkr.ecr.eu-1 west-3.amazonaws.com/ object-detection:<tag>		inference, training		

## Object2Vec (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='object2vec',region='eu-west-3')
```

Registry path	Version	Job types (image scope)		
749696950732.dkr.ecr.eu-1 west-3.amazonaws.com/ object2vec:<tag>		inference, training		

## PCA (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='pca',region='eu-west-3')
```

Registry path	Version	Job types (image scope)		
749696950732.dkr.ecr.eu-1 west-3.amazonaws.com/ pca:<tag>		inference, training		

## PyTorch (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='pytorch',region='eu-
west-3',version='1.8.0',py_version='py3',image_scope='inference',
instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
520713654638.dkr.e0.40-west-3.amazonaws.com/sagemaker-pytorch:<tag>		inference	CPU, GPU	py2, py3
520713654638.dkr.e0.40-west-3.amazonaws.com/sagemaker-pytorch:<tag>		training	CPU, GPU	py2, py3
520713654638.dkr.edr.0.0-west-3.amazonaws.com/sagemaker-pytorch:<tag>		inference	CPU, GPU	py2, py3
520713654638.dkr.edr.0.0-west-3.amazonaws.com/sagemaker-pytorch:<tag>		training	CPU, GPU	py2, py3
520713654638.dkr.edr.1.0-west-3.amazonaws.com/sagemaker-pytorch:<tag>		inference	CPU, GPU	py2, py3
520713654638.dkr.edr.1.0-west-3.amazonaws.com/sagemaker-pytorch:<tag>		training	CPU, GPU	py2, py3
763104351884.dkr.edr.3.1-west-3.amazonaws.com/pytorch-inference-eia:<tag>		eia	CPU	py3
763104351884.dkr.edr.2.0-west-3.amazonaws.com/pytorch-inference:<tag>		inference	CPU, GPU	py2, py3
763104351884.dkr.edr.3.1-west-3.amazonaws.com/pytorch-inference:<tag>		inference	CPU, GPU	py2, py3
763104351884.dkr.edr.4.0-west-3.amazonaws.com/pytorch-inference:<tag>		inference	CPU, GPU	py3
763104351884.dkr.edr.5.0-west-3.amazonaws.com/pytorch-inference:<tag>		inference	CPU, GPU	py3

Registry path	Version	Job types (image scope)	Processor types	Python versions
763104351884.dkr.edr. <b>6.0</b> -west-3.amazonaws.com/pytorch-inference:<tag>		inference	CPU, GPU	py3, py36
763104351884.dkr.edr. <b>7.1</b> -west-3.amazonaws.com/pytorch-inference:<tag>		inference	CPU, GPU	py3, py36
763104351884.dkr.edr. <b>8.0</b> -west-3.amazonaws.com/pytorch-inference:<tag>		inference	CPU, GPU	py3, py36
763104351884.dkr.edr. <b>8.1</b> -west-3.amazonaws.com/pytorch-inference:<tag>		inference	CPU, GPU	py3, py36
763104351884.dkr.edr. <b>2.0</b> -west-3.amazonaws.com/pytorch-training:<tag>		training	CPU, GPU	py2, py3
763104351884.dkr.edr. <b>3.1</b> -west-3.amazonaws.com/pytorch-training:<tag>		training	CPU, GPU	py2, py3
763104351884.dkr.edr. <b>4.0</b> -west-3.amazonaws.com/pytorch-training:<tag>		training	CPU, GPU	py2, py3
763104351884.dkr.edr. <b>5.0</b> -west-3.amazonaws.com/pytorch-training:<tag>		training	CPU, GPU	py3
763104351884.dkr.edr. <b>6.0</b> -west-3.amazonaws.com/pytorch-training:<tag>		training	CPU, GPU	py3, py36
763104351884.dkr.edr. <b>7.1</b> -west-3.amazonaws.com/pytorch-training:<tag>		training	CPU, GPU	py3, py36
763104351884.dkr.edr. <b>8.0</b> -west-3.amazonaws.com/pytorch-training:<tag>		training	CPU, GPU	py3, py36

Registry path	Version	Job types (image scope)	Processor types	Python versions
763104351884.dkr.ecr.eu-west-3.amazonaws.com/pytorch-training:<tag>		training	CPU, GPU	py3, py36

### Random Cut Forest (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='randomcutforest',region='eu-west-3')
```

Registry path	Version	Job types (image scope)		
749696950732.dkr.ecr.eu-west-3.amazonaws.com/randomcutforest:<tag>		inference, training		

### Scikit-learn (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='sklearn',region='eu-west-3',version='0.23-1',image_scope='inference')
```

Registry path	Version	Job types (image scope)		
659782779980.dkr.ecr.eu-west-3.amazonaws.com/sagemaker-scikit-learn:<tag>	0.20.0	inference, training		
659782779980.dkr.ecr.eu-west-3.amazonaws.com/sagemaker-scikit-learn:<tag>	0.23-1	inference, training		

### Semantic Segmentation (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='semantic-segmentation',region='eu-west-3')
```

Registry path	Version	Job types (image scope)		
749696950732.dkr.ecr.eu-1 west-3.amazonaws.com/ semantic-segmentation:<tag>		inference, training		

## Seq2Seq (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='seq2seq',region='eu-west-3')
```

Registry path	Version	Job types (image scope)		
749696950732.dkr.ecr.eu-1 west-3.amazonaws.com/ seq2seq:<tag>		inference, training		

## Spark (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='spark',region='eu-west-3',version='3.0',image_scope='processing')
```

Registry path	Version	Job types (image scope)		
136845547031.dkr.ecr.eu-2.4 west-3.amazonaws.com/ sagemaker-spark-processing:<tag>		processing		
136845547031.dkr.ecr.eu-3.0 west-3.amazonaws.com/ sagemaker-spark-processing:<tag>		processing		

## SparkML Serving (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='sparkml-serving',region='eu-west-3',version='2.4')
```

Registry path	Version	Job types (image scope)		
659782779980.dkr.ecr.eu-2.2 west-3.amazonaws.com/ sagemaker-sparkml- serving:<tag>		inference		
659782779980.dkr.ecr.eu-2.4 west-3.amazonaws.com/ sagemaker-sparkml- serving:<tag>		inference		

## Tensorflow (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='tensorflow', region='eu-west-3', version='1.12.0', image_scope='inference', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
520713654638.dkr.ecr.eu-10.0 west-3.amazonaws.com/ sagemaker- tensorflow- eia:<tag>		eia	CPU	py2

### Tensorflow Coach (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='coach-tensorflow', region='eu-west-3', version='1.0.0', image_scope='training', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
520713654638.dkr.e <u>0.10</u> -west-3.amazonaws.com/sagemaker-rl-tensorflow:coach0.10-<tag>		training	CPU, GPU	py3
520713654638.dkr.e <u>0.10.1</u> -west-3.amazonaws.com/sagemaker-rl-tensorflow:coach0.10.1-<tag>		training	CPU, GPU	py3
520713654638.dkr.e <u>0.11</u> -west-3.amazonaws.com/sagemaker-rl-tensorflow:coach0.11-<tag>		training	CPU, GPU	py3
520713654638.dkr.e <u>0.11.0</u> -west-3.amazonaws.com/sagemaker-rl-tensorflow:coach0.11.0-<tag>		training	CPU, GPU	py3
520713654638.dkr.e <u>0.11.1</u> -west-3.amazonaws.com/sagemaker-rl-		training	CPU, GPU	py3

Registry path	Version	Job types (image scope)	Processor types	Python versions
tensorflow:coach0.11.1- <i>&lt;tag&gt;</i>				

## Tensorflow Inference (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='inferentia-tensorflow', region='eu-west-3', version='1.15.0', instance_type='ml.inf1.6xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
254080097072.dkr.e0r.15.0 west-3.amazonaws.com/ sagemaker-neo-tensorflow: <i>&lt;tag&gt;</i>		inference	inf	py3

## Tensorflow Ray (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='ray-tensorflow', region='eu-west-3', version='0.8.5', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
520713654638.dkr.e0r.5eu-west-3.amazonaws.com/ sagemaker-rl-tensorflow:ray0.5- <i>&lt;tag&gt;</i>		training	CPU, GPU	py3
520713654638.dkr.e0r.5.3- west-3.amazonaws.com/ sagemaker-rl-tensorflow:ray0.5.3- <i>&lt;tag&gt;</i>		training	CPU, GPU	py3
520713654638.dkr.e0r.6eu-west-3.amazonaws.com/ sagemaker-rl-tensorflow:ray0.6- <i>&lt;tag&gt;</i>		training	CPU, GPU	py3
520713654638.dkr.e0r.6.5- west-3.amazonaws.com/ sagemaker-rl-		training	CPU, GPU	py3

Registry path	Version	Job types (image scope)	Processor types	Python versions
tensorflow:ray0.6.5-<tag>				

## XGBoost (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='xgboost', region='eu-west-3', version='1.2-1')
```

Registry path	Version	Job types (image scope)		
659782779980.dkr.ecr.eu-west-3.amazonaws.com/sagemaker-xgboost:<tag>		inference, training		
659782779980.dkr.ecr.eu-west-3.amazonaws.com/sagemaker-xgboost:<tag>		inference, training		
659782779980.dkr.ecr.eu-west-3.amazonaws.com/sagemaker-xgboost:<tag>		inference, training		
659782779980.dkr.ecr.eu-west-3.amazonaws.com/sagemaker-xgboost:<tag>		inference, training		
659782779980.dkr.ecr.eu-west-3.amazonaws.com/sagemaker-xgboost:<tag>		inference, training		
659782779980.dkr.ecr.eu-west-3.amazonaws.com/sagemaker-xgboost:<tag>		inference, training		
749696950732.dkr.ecr.eu-west-3.amazonaws.com/xgboost:<tag>		inference, training		

## Docker Registry Paths and Example Code for Europe (Stockholm) (eu-north-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

### Topics

- [BlazingText \(algorithm\) \(p. 1220\)](#)
- [Chainer \(DLC\) \(p. 1221\)](#)

## [BlazingText \(algorithm\)](#)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='blazingtext', region='eu-north-1')
```

Registry path	Version	Job types (image scope)		
669576153137.dkr.ecr.eu-north-1.amazonaws.com/blazingtext:<tag>		inference, training		

### Chainer (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='chainer', region='eu-north-1', version='5.0.0', py_version='py3', image_scope='inference', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
520713654638.dkr.ecr.eu-north-1.amazonaws.com/sagemaker-chainer:<tag>		inference, training	CPU, GPU	py2, py3
520713654638.dkr.ecr.eu-north-1.amazonaws.com/sagemaker-chainer:<tag>		inference, training	CPU, GPU	py2, py3
520713654638.dkr.ecr.eu-north-1.amazonaws.com/sagemaker-chainer:<tag>		inference, training	CPU, GPU	py2, py3

### Clarify (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='clarify', region='eu-north-1', version='1.0', image_scope='processing')
```

Registry path	Version	Job types (image scope)		
763603941244.dkr.ecr.eu-1.0-north-1.amazonaws.com/sagemaker-clarify-processing:<tag>		processing		

## Data Wrangler (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='data-wrangler',region='eu-north-1')
```

Registry path	Version	Job types (image scope)		
054986407534.dkr.ecr.eu-1.x north-1.amazonaws.com/ sagemaker- data-wrangler- container:<tag>		processing		

## Debugger (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='debugger',region='eu-north-1')
```

Registry path	Version	Job types (image scope)		
314864569078.dkr.ecr.eu-latest north-1.amazonaws.com/ sagemaker-debugger- rules:<tag>		debugger		

## DeepAR Forecasting (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='forecasting-deepar',region='eu-north-1')
```

Registry path	Version	Job types (image scope)		
669576153137.dkr.ecr.eu-1 north-1.amazonaws.com/ forecasting- deepar:<tag>		inference, training		

## Factorization Machines (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='factorization-machines',region='eu-north-1')
```

Registry path	Version	Job types (image scope)		
669576153137.dkr.ecr.eu-1 north-1.amazonaws.com/ factorization- machines:<tag>		inference, training		

## Hugging Face (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='huggingface', region='eu-north-1', version='4.4.2', image_scope='training', base_framework_version='tensorflow2.4.1')
```

Registry path	Version	Job types (image scope)		
763104351884.dkr.ecr.eu-4.4.2 north-1.amazonaws.com/ huggingface-pytorch- training:<tag>		training		
763104351884.dkr.ecr.eu-4.5.0 north-1.amazonaws.com/ huggingface-pytorch- training:<tag>		training		
763104351884.dkr.ecr.eu-4.4.2 north-1.amazonaws.com/ huggingface- tensorflow- training:<tag>		training		
763104351884.dkr.ecr.eu-4.5.0 north-1.amazonaws.com/ huggingface- tensorflow- training:<tag>		training		

## IP Insights (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='ipinsights', region='eu-north-1')
```

Registry path	Version	Job types (image scope)		
669576153137.dkr.ecr.eu-1 north-1.amazonaws.com/ ipinsights:<tag>		inference, training		

## Image classification (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='image-classification', region='eu-north-1')
```

Registry path	Version	Job types (image scope)		
669576153137.dkr.ecr.eu-1-north-1.amazonaws.com/image-classification:<tag>		inference, training		

## Inferentia MXNet (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='inferentia-mxnet', region='eu-north-1', version='1.5.1', instance_type='ml.inf1.6xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
601324751636.dkr.ecr.eu-1-north-1.amazonaws.com/sagemaker-neo-mxnet:<tag>		inference	inf	py3

## Inferentia PyTorch (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='inferentia-pytorch', region='eu-north-1', version='1.5.1', py_version='py3')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
601324751636.dkr.ecr.eu-1-north-1.amazonaws.com/sagemaker-neo-pytorch:<tag>		inference	inf	py3

## K-Means (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
```

```
image_uris.retrieve(framework='kmeans', region='eu-north-1')
```

Registry path	Version	Job types (image scope)		
669576153137.dkr.ecr.eu-1 north-1.amazonaws.com/ kmeans:<tag>		inference, training		

### KNN (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='knn', region='eu-north-1')
```

Registry path	Version	Job types (image scope)		
669576153137.dkr.ecr.eu-1 north-1.amazonaws.com/ knn:<tag>		inference, training		

### Linear Learner (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='linear-learner', region='eu-north-1')
```

Registry path	Version	Job types (image scope)		
669576153137.dkr.ecr.eu-1 north-1.amazonaws.com/ linear-learner:<tag>		inference, training		

### MXNet (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='mxnet', region='eu-north-1', version='1.4.1', py_version='py3', image_scope='inference',
instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
520713654638.dkr.ecr.eu-1 north-1.amazonaws.com/		eia	CPU	py2, py3

Registry path	Version	Job types (image scope)	Processor types	Python versions
sagemaker-mxnet-eia:<tag>

## MXNet Coach (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='coach-mxnet', region='eu-north-1', version='0.11', py_version='py3', image_scope='training', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
520713654638.dkr.edr. <del>0.11</del> -north-1.amazonaws.com/sagemaker-rl-mxnet:coach0.11-<tag>		training	CPU, GPU	py3
520713654638.dkr.edr. <del>0.11.0</del> -north-1.amazonaws.com/sagemaker-rl-mxnet:coach0.11.0-<tag>		training	CPU, GPU	py3

## Model Monitor (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
```

```
image_uris.retrieve(framework='model-monitor',region='eu-north-1')
```

Registry path	Version	Job types (image scope)		
895015795356.dkr.ecr.eu-north-1.amazonaws.com/sagemaker-model-monitor-analyzer:<tag>		monitoring		

### NTM (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='ntm',region='eu-north-1')
```

Registry path	Version	Job types (image scope)		
669576153137.dkr.ecr.eu-north-1.amazonaws.com/ntm:<tag>		inference, training		

### Neo Image Classification (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='image-classification-neo',region='eu-north-1')
```

Registry path	Version	Job types (image scope)		
601324751636.dkr.ecr.eu-north-1.amazonaws.com/image-classification-neo:<tag>	latest	inference		

### Neo MXNet (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='neo-mxnet',region='eu-north-1',version='1.8',py_version='py3',image_scope='inference',instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
601324751636.dkr.e <u>u</u> -north-1.amazonaws.com/sagemaker-inference-mxnet:<tag>		inference	CPU, GPU	py3

### Neo PyTorch (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='neo-pytorch', region='eu-north-1', version='1.6', image_scope='inference', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
601324751636.dkr.e <u>u</u> -north-1.amazonaws.com/sagemaker-inference-pytorch:<tag>		inference	CPU, GPU	py3
601324751636.dkr.e <u>u</u> -north-1.amazonaws.com/sagemaker-inference-pytorch:<tag>		inference	CPU, GPU	py3
601324751636.dkr.e <u>u</u> -north-1.amazonaws.com/sagemaker-inference-pytorch:<tag>		inference	CPU, GPU	py3

### Neo Tensorflow (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='neo-tensorflow', region='eu-north-1', version='1.15.3', py_version='py3', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
601324751636.dkr.e <u>u</u> .3-north-1.amazonaws.com/sagemaker-inference-tensorflow:<tag>		inference	CPU, GPU	py3

## Neo XGBoost (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='xgboost-neo', region='eu-north-1')
```

Registry path	Version	Job types (image scope)		
601324751636.dkr.ecr.eu-north-1.amazonaws.com/xgboost-neo:<tag>		inference		

## Object Detection (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='object-detection', region='eu-north-1')
```

Registry path	Version	Job types (image scope)		
669576153137.dkr.ecr.eu-north-1.amazonaws.com/object-detection:<tag>		inference, training		

## Object2Vec (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='object2vec', region='eu-north-1')
```

Registry path	Version	Job types (image scope)		
669576153137.dkr.ecr.eu-north-1.amazonaws.com/object2vec:<tag>		inference, training		

## PCA (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='pca', region='eu-north-1')
```

Registry path	Version	Job types (image scope)		
669576153137.dkr.ecr.eu-1 north-1.amazonaws.com/ pca:<tag>		inference, training		

## PyTorch (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='pytorch', region='eu-north-1', version='1.8.0', py_version='py3', image_scope='inference',
instance_type='ml.c5.4xlarge')
```

## Random Cut Forest (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='randomcutforest', region='eu-north-1')
```

Registry path	Version	Job types (image scope)		
669576153137.dkr.ecr.eu-north-1.amazonaws.com/randomcutforest:<tag>		inference, training		

## Scikit-learn (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='sklearn', region='eu-north-1', version='0.23-1', image_scope='inference')
```

Registry path	Version	Job types (image scope)		
662702820516.dkr.ecr.eu-0.20.0-north-1.amazonaws.com/		inference, training		

Registry path	Version	Job types (image scope)		
sagemaker-scikit-learn:<tag>				
662702820516.dkr.ecr.eu-0.23-1 north-1.amazonaws.com/ sagemaker-scikit-learn:<tag>		inference, training		

### Semantic Segmentation (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='semantic-segmentation', region='eu-north-1')
```

Registry path	Version	Job types (image scope)		
669576153137.dkr.ecr.eu-1 north-1.amazonaws.com/ semantic-segmentation:<tag>		inference, training		

### Seq2Seq (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='seq2seq', region='eu-north-1')
```

Registry path	Version	Job types (image scope)		
669576153137.dkr.ecr.eu-1 north-1.amazonaws.com/ seq2seq:<tag>		inference, training		

### Spark (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='spark', region='eu-north-1', version='3.0', image_scope='processing')
```

Registry path	Version	Job types (image scope)		
330188676905.dkr.ecr.eu-2.4 north-1.amazonaws.com/		processing		

Registry path	Version	Job types (image scope)		
sagemaker-spark-processing:<tag>				
330188676905.dkr.ecr.eu-3.0 north-1.amazonaws.com/ sagemaker-spark-processing:<tag>		processing		

## SparkML Serving (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='sparkml-serving', region='eu-north-1', version='2.4')
```

Registry path	Version	Job types (image scope)		
662702820516.dkr.ecr.eu-2.2 north-1.amazonaws.com/ sagemaker-sparkml-serving:<tag>		inference		
662702820516.dkr.ecr.eu-2.4 north-1.amazonaws.com/ sagemaker-sparkml-serving:<tag>		inference		

## Tensorflow (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='tensorflow', region='eu-north-1', version='1.12.0', image_scope='inference', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions

### Tensorflow Coach (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='coach-tensorflow', region='eu-north-1', version='1.0.0', image_scope='training', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
520713654638.dkr.e <u>0.10</u> -north-1.amazonaws.com/sagemaker-rl-		training	CPU, GPU	py3

Registry path	Version	Job types (image scope)	Processor types	Python versions
tensorflow:coach0.10-<tag>				
520713654638.dkr.e0.10.1 north-1.amazonaws.com/sagemaker-rl-tensorflow:coach0.10.1-<tag>		training	CPU, GPU	py3
520713654638.dkr.e0.11.1 north-1.amazonaws.com/sagemaker-rl-tensorflow:coach0.11.1-<tag>		training	CPU, GPU	py3
520713654638.dkr.e0.11.0 north-1.amazonaws.com/sagemaker-rl-tensorflow:coach0.11.0-<tag>		training	CPU, GPU	py3
520713654638.dkr.e0.11.1 north-1.amazonaws.com/sagemaker-rl-tensorflow:coach0.11.1-<tag>		training	CPU, GPU	py3

## Tensorflow Inference (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='inferentia-tensorflow', region='eu-north-1', version='1.15.0', instance_type='ml.inf1.6xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
601324751636.dkr.e0.15.0 north-1.amazonaws.com/sagemaker-neo-tensorflow:<tag>		inference	inf	py3

## Tensorflow Ray (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='ray-tensorflow', region='eu-north-1', version='0.8.5', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
520713654638.dkr.e0.5eu-north-1.amazonaws.com/sagemaker-rl-tensorflow:ray0.5-<tag>		training	CPU, GPU	py3
520713654638.dkr.e0.5.3eu-north-1.amazonaws.com/sagemaker-rl-tensorflow:ray0.5.3-<tag>		training	CPU, GPU	py3
520713654638.dkr.e0.6eu-north-1.amazonaws.com/sagemaker-rl-tensorflow:ray0.6-<tag>		training	CPU, GPU	py3
520713654638.dkr.e0.6.5eu-north-1.amazonaws.com/sagemaker-rl-tensorflow:ray0.6.5-<tag>		training	CPU, GPU	py3

## XGBoost (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='xgboost',region='eu-north-1',version='1.2-1')
```

Registry path	Version	Job types (image scope)		
662702820516.dkr.ecr.eu-0.90-1north-1.amazonaws.com/sagemaker-xgboost:<tag>		inference, training		
662702820516.dkr.ecr.eu-0.90-2north-1.amazonaws.com/sagemaker-xgboost:<tag>		inference, training		
662702820516.dkr.ecr.eu-1.0-1north-1.amazonaws.com/sagemaker-xgboost:<tag>		inference, training		
662702820516.dkr.ecr.eu-1.2-1north-1.amazonaws.com/sagemaker-xgboost:<tag>		inference, training		

Registry path	Version	Job types (image scope)		
662702820516.dkr.ecr.eu-1.2-2 north-1.amazonaws.com/ sagemaker- xgboost:<tag>		inference, training		
662702820516.dkr.ecr.eu-1.3-1 north-1.amazonaws.com/ sagemaker- xgboost:<tag>		inference, training		
669576153137.dkr.ecr.eu-1 north-1.amazonaws.com/ xgboost:<tag>		inference, training		

### Docker Registry Paths and Example Code for Europe (Milan) (eu-south-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

#### Topics

- [BlazingText \(algorithm\) \(p. 1247\)](#)
- [Chainer \(DLC\) \(p. 1247\)](#)
- [Clarify \(algorithm\) \(p. 1248\)](#)
- [Data Wrangler \(algorithm\) \(p. 1248\)](#)
- [Debugger \(algorithm\) \(p. 1248\)](#)
- [DeepAR Forecasting \(algorithm\) \(p. 1248\)](#)

### [BlazingText \(algorithm\)](#)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='blazingtext',region='eu-south-1')
```

Registry path	Version	Job types (image scope)		
257386234256.dkr.ecr.eu-south-1.amazonaws.com/blazingtext:<tag>		inference, training		

### [Chainer \(DLC\)](#)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='chainer',region='eu-south-1',version='5.0.0',py_version='py3',image_scope='inference',instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
048378556238.dkr.ecr.eu-south-1.amazonaws.com/sagemaker-chainer:<tag>	4.10.0	inference, training	CPU, GPU	py2, py3
048378556238.dkr.ecr.eu-south-1.amazonaws.com/sagemaker-chainer:<tag>	4.11.0	inference, training	CPU, GPU	py2, py3
048378556238.dkr.ecr.eu-south-1.amazonaws.com/sagemaker-chainer:<tag>	5.0.0	inference, training	CPU, GPU	py2, py3

## Clarify (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='clarify',region='eu-south-1',version='1.0',image_scope='processing')
```

Registry path	Version	Job types (image scope)		
638885417683.dkr.ecr.eu-1.0.south-1.amazonaws.com/sagemaker-clarify-processing:<tag>		processing		

## Data Wrangler (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='data-wrangler',region='eu-south-1')
```

Registry path	Version	Job types (image scope)		
488287956546.dkr.ecr.eu-1.x.south-1.amazonaws.com/sagemaker-data-wrangler-container:<tag>		processing		

## Debugger (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='debugger',region='eu-south-1')
```

Registry path	Version	Job types (image scope)		
563282790590.dkr.ecr.eu-latest.south-1.amazonaws.com/sagemaker-debugger-rules:<tag>		debugger		

## DeepAR Forecasting (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
```

```
image_uris.retrieve(framework='forecasting-deepar', region='eu-south-1')
```

Registry path	Version	Job types (image scope)		
257386234256.dkr.ecr.eu-1.south-1.amazonaws.com/forecasting-deepar:<tag>		inference, training		

### Factorization Machines (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='factorization-machines', region='eu-south-1')
```

Registry path	Version	Job types (image scope)		
257386234256.dkr.ecr.eu-1.south-1.amazonaws.com/factorization-machines:<tag>		inference, training		

### Hugging Face (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='huggingface', region='eu-south-1', version='4.4.2', image_scope='training', base_framework_version='tensorflow2.4.1')
```

Registry path	Version	Job types (image scope)		
692866216735.dkr.ecr.eu-4.4.2.south-1.amazonaws.com/huggingface-pytorch-training:<tag>		training		
692866216735.dkr.ecr.eu-4.5.0.south-1.amazonaws.com/huggingface-pytorch-training:<tag>		training		
692866216735.dkr.ecr.eu-4.4.2.south-1.amazonaws.com/huggingface-tensorflow-training:<tag>		training		
692866216735.dkr.ecr.eu-4.5.0.south-1.amazonaws.com/		training		

Registry path	Version	Job types (image scope)		
huggingface-tensorflow-training:<tag>				

## IP Insights (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='ipinsights',region='eu-south-1')
```

Registry path	Version	Job types (image scope)		
257386234256.dkr.ecr.eu-south-1.amazonaws.com/ipinsights:<tag>		inference, training		

## Image classification (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='image-classification',region='eu-south-1')
```

Registry path	Version	Job types (image scope)		
257386234256.dkr.ecr.eu-south-1.amazonaws.com/image-classification:<tag>		inference, training		

## Inferentia MXNet (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='inferentia-mxnet',region='eu-south-1',version='1.5.1',instance_type='ml.inf1.6xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
966458181534.dkr.ecr.eu-south-1.amazonaws.com/sagemaker-neo-mxnet:<tag>		inference	inf	py3

## Inferentia PyTorch (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='inferentia-pytorch',region='eu-south-1',version='1.5.1',py_version='py3')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
966458181534.dkr.ecr.eu-south-1.amazonaws.com/sagemaker-neo-pytorch:<tag>		inference	inf	py3

## K-Means (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='kmeans',region='eu-south-1')
```

Registry path	Version	Job types (image scope)		
257386234256.dkr.ecr.eu-south-1.amazonaws.com/kmeans:<tag>		inference, training		

## KNN (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='knn',region='eu-south-1')
```

Registry path	Version	Job types (image scope)		
257386234256.dkr.ecr.eu-south-1.amazonaws.com/knn:<tag>		inference, training		

## Linear Learner (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='linear-learner',region='eu-south-1')
```

Registry path	Version	Job types (image scope)		
257386234256.dkr.ecr.eu-south-1.amazonaws.com/linear-learner:<tag>		inference, training		

## MXNet (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='mxnet', region='eu-south-1', version='1.4.1', py_version='py3', image_scope='inference', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
048378556238.dkr.edr.10-south-1.amazonaws.com/sagemaker-mxnet-eia:<tag>		eia	CPU	py2, py3
048378556238.dkr.edr.10-south-1.amazonaws.com/sagemaker-mxnet-serving-eia:<tag>		eia	CPU	py2, py3
048378556238.dkr.edr.10-south-1.amazonaws.com/sagemaker-mxnet-serving:<tag>		inference	CPU, GPU	py2, py3
048378556238.dkr.edr.11-south-1.amazonaws.com/sagemaker-mxnet-serving:<tag>		inference	CPU, GPU	py2
048378556238.dkr.e0.12.1south-1.amazonaws.com/sagemaker-mxnet:<tag>		inference	CPU, GPU	py2, py3
048378556238.dkr.e0.12.1south-1.amazonaws.com/sagemaker-mxnet:<tag>		training	CPU, GPU	py2, py3
048378556238.dkr.e0.10-south-1.amazonaws.com/sagemaker-mxnet:<tag>		inference	CPU, GPU	py2, py3
048378556238.dkr.e0.10-south-1.amazonaws.com/		training	CPU, GPU	py2, py3

Registry path	Version	Job types (image scope)	Processor types	Python versions
sagemaker-mxnet:<tag>				
048378556238.dkr.edr.10-south-1.amazonaws.com/sagemaker-mxnet:<tag>		inference	CPU, GPU	py2, py3
048378556238.dkr.edr.10-south-1.amazonaws.com/sagemaker-mxnet:<tag>		training	CPU, GPU	py2, py3
048378556238.dkr.edr.21-south-1.amazonaws.com/sagemaker-mxnet:<tag>		inference	CPU, GPU	py2, py3
048378556238.dkr.edr.21-south-1.amazonaws.com/sagemaker-mxnet:<tag>		training	CPU, GPU	py2, py3
048378556238.dkr.edr.30-south-1.amazonaws.com/sagemaker-mxnet:<tag>		inference	CPU, GPU	py2, py3
048378556238.dkr.edr.30-south-1.amazonaws.com/sagemaker-mxnet:<tag>		training	CPU, GPU	py2, py3
048378556238.dkr.edr.40-south-1.amazonaws.com/sagemaker-mxnet:<tag>		training	CPU, GPU	py2, py3

692866216735.dkr.eur.7.0-south-1.amazonaws.com/mxnet-training:<tag>		training	CPU, GPU	py3
692866216735.dkr.eur.8.0-south-1.amazonaws.com/mxnet-training:<tag>		training	CPU, GPU	py37

## MXNet Coach (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='coach-mxnet', region='eu-south-1', version='0.11', py_version='py3', image_scope='training', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
048378556238.dkr.ecr.eu-south-1.amazonaws.com/sagemaker-rl-mxnet:coach0.11-<tag>		training	CPU, GPU	py3
048378556238.dkr.ecr.eu-south-1.amazonaws.com/sagemaker-rl-mxnet:coach0.11.0-<tag>		training	CPU, GPU	py3

### Model Monitor (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='model-monitor', region='eu-south-1')
```

Registry path	Version	Job types (image scope)		
933208885752.dkr.ecr.eu-south-1.amazonaws.com/sagemaker-model-monitor-analyzer:<tag>		monitoring		

### NTM (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='ntm', region='eu-south-1')
```

Registry path	Version	Job types (image scope)		
257386234256.dkr.ecr.eu-south-1.amazonaws.com/ntm:<tag>		inference, training		

### Neo Image Classification (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='image-classification-neo', region='eu-south-1')
```

Registry path	Version	Job types (image scope)		
966458181534.dkr.ecr.eu-south-1.amazonaws.com/image-classification-neo:<tag>	latest	inference		

### Neo MXNet (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='neo-mxnet', region='eu-south-1', version='1.8', py_version='py3', image_scope='inference', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
966458181534.dkr.ecr.eu-south-1.amazonaws.com/sagemaker-inference-mxnet:<tag>		inference	CPU, GPU	py3

### Neo PyTorch (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='neo-pytorch', region='eu-south-1', version='1.6', image_scope='inference', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
966458181534.dkr.ecr.eu-south-1.amazonaws.com/sagemaker-inference-pytorch:<tag>		inference	CPU, GPU	py3
966458181534.dkr.ecr.eu-south-1.amazonaws.com/sagemaker-inference-pytorch:<tag>		inference	CPU, GPU	py3
966458181534.dkr.ecr.eu-south-1.amazonaws.com/sagemaker-inference-pytorch:<tag>		inference	CPU, GPU	py3

## Neo Tensorflow (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='neo-tensorflow',region='eu-south-1',version='1.15.3',py_version='py3',instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
966458181534.dkr.ecr.eu-south-1.amazonaws.com/sagemaker-inference-tensorflow:<tag>		inference	CPU, GPU	py3

## Neo XGBoost (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='xgboost-neo',region='eu-south-1')
```

Registry path	Version	Job types (image scope)		
966458181534.dkr.ecr.eu-south-1.amazonaws.com/xgboost-neo:<tag>	latest	inference		

## Object Detection (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='object-detection',region='eu-south-1')
```

Registry path	Version	Job types (image scope)		
257386234256.dkr.ecr.eu-south-1.amazonaws.com/object-detection:<tag>		inference, training		

## Object2Vec (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='object2vec',region='eu-south-1')
```

Registry path	Version	Job types (image scope)		
257386234256.dkr.ecr.eu-1.south-1.amazonaws.com/object2vec:<tag>		inference, training		

### PCA (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='pca', region='eu-south-1')
```

Registry path	Version	Job types (image scope)		
257386234256.dkr.ecr.eu-1.south-1.amazonaws.com/pca:<tag>		inference, training		

### PyTorch (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='pytorch', region='eu-south-1', version='1.8.0', py_version='py3', image_scope='inference',
 instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
048378556238.dkr.e0.40-south-1.amazonaws.com/sagemaker-pytorch:<tag>		inference	CPU, GPU	py2, py3
048378556238.dkr.e0.40-south-1.amazonaws.com/sagemaker-pytorch:<tag>		training	CPU, GPU	py2, py3
048378556238.dkr.edr.0.0-south-1.amazonaws.com/sagemaker-pytorch:<tag>		inference	CPU, GPU	py2, py3

## Random Cut Forest (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='randomcutforest', region='eu-south-1')
```

Registry path	Version	Job types (image scope)		
257386234256.dkr.ecr.eu-1-south-1.amazonaws.com/randomcutforest:<tag>		inference, training		

## Scikit-learn (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='sklearn',region='eu-south-1',version='0.23-1',image_scope='inference')
```

Registry path	Version	Job types (image scope)		
978288397137.dkr.ecr.eu-0.20.0.south-1.amazonaws.com/sagemaker-scikit-learn:<tag>		inference, training		
978288397137.dkr.ecr.eu-0.23-1.south-1.amazonaws.com/sagemaker-scikit-learn:<tag>		inference, training		

## Semantic Segmentation (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='semantic-segmentation',region='eu-south-1')
```

Registry path	Version	Job types (image scope)		
257386234256.dkr.ecr.eu-1.south-1.amazonaws.com/semantic-segmentation:<tag>		inference, training		

## Seq2Seq (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='seq2seq',region='eu-south-1')
```

Registry path	Version	Job types (image scope)		
257386234256.dkr.ecr.eu-1.south-1.amazonaws.com/seq2seq:<tag>		inference, training		

## Spark (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='spark',region='eu-south-1',version='3.0',image_scope='processing')
```

Registry path	Version	Job types (image scope)		
753923664805.dkr.ecr.eu-2.4.south-1.amazonaws.com/sagemaker-spark-processing:<tag>		processing		
753923664805.dkr.ecr.eu-3.0.south-1.amazonaws.com/sagemaker-spark-processing:<tag>		processing		

### SparkML Serving (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='sparkml-serving',region='eu-south-1',version='2.4')
```

Registry path	Version	Job types (image scope)		
978288397137.dkr.ecr.eu-2.2.south-1.amazonaws.com/sagemaker-sparkml-serving:<tag>		inference		
978288397137.dkr.ecr.eu-2.4.south-1.amazonaws.com/sagemaker-sparkml-serving:<tag>		inference		

### Tensorflow (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='tensorflow',region='eu-south-1',version='1.12.0',image_scope='inference',instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions

## Tensorflow Coach (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='coach-tensorflow', region='eu-south-1', version='1.0.0', image_scope='training', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
048378556238.dkr.e0.10-south-1.amazonaws.com/sagemaker-rl-tensorflow:coach0.10-<tag>		training	CPU, GPU	py3
048378556238.dkr.e0.10.1-south-1.amazonaws.com/sagemaker-rl-tensorflow:coach0.10.1-<tag>		training	CPU, GPU	py3
048378556238.dkr.e0.11-south-1.amazonaws.com/sagemaker-rl-tensorflow:coach0.11-<tag>		training	CPU, GPU	py3
048378556238.dkr.e0.11.0-south-1.amazonaws.com/sagemaker-rl-tensorflow:coach0.11.0-<tag>		training	CPU, GPU	py3
048378556238.dkr.e0.11.1-south-1.amazonaws.com/sagemaker-rl-tensorflow:coach0.11.1-<tag>		training	CPU, GPU	py3

### Tensorflow Inferentia (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='inferentia-tensorflow', region='eu-south-1', version='1.15.0', instance_type='ml.inf1.6xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
966458181534.dkr.e0.15.0-south-1.amazonaws.com/sagemaker-neo-tensorflow:<tag>		inference	inf	py3

### Tensorflow Ray (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
```

```
image_uris.retrieve(framework='ray-tensorflow',region='eu-south-1',version='0.8.5',instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
048378556238.dkr.e <u>0.5</u> -south-1.amazonaws.com/sagemaker-rl-tensorflow:ray0.5-<tag>		training	CPU, GPU	py3
048378556238.dkr.e <u>0.5.3</u> -south-1.amazonaws.com/sagemaker-rl-tensorflow:ray0.5.3-<tag>		training	CPU, GPU	py3
048378556238.dkr.e <u>0.6</u> -south-1.amazonaws.com/sagemaker-rl-tensorflow:ray0.6-<tag>		training	CPU, GPU	py3
048378556238.dkr.e <u>0.6.5</u> -south-1.amazonaws.com/sagemaker-rl-tensorflow:ray0.6.5-<tag>		training	CPU, GPU	py3

## XGBoost (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='xgboost',region='eu-south-1',version='1.2-1')
```

Registry path	Version	Job types (image scope)		
257386234256.dkr.ecr.eu-1-south-1.amazonaws.com/xgboost:<tag>		inference, training		
978288397137.dkr.ecr.eu-0.90-1-south-1.amazonaws.com/sagemaker-xgboost:<tag>		inference, training		
978288397137.dkr.ecr.eu-0.90-2-south-1.amazonaws.com/sagemaker-xgboost:<tag>		inference, training		
978288397137.dkr.ecr.eu-1.0-1-south-1.amazonaws.com/		inference, training		

Registry path	Version	Job types (image scope)		
sagemaker-xgboost:<tag>				
978288397137.dkr.ecr.eu-1.2-1 south-1.amazonaws.com/ sagemaker-xgboost:<tag>		inference, training		
978288397137.dkr.ecr.eu-1.2-2 south-1.amazonaws.com/ sagemaker-xgboost:<tag>		inference, training		
978288397137.dkr.ecr.eu-1.3-1 south-1.amazonaws.com/ sagemaker-xgboost:<tag>		inference, training		

## Docker Registry Paths and Example Code for Middle East (Bahrain) (me-south-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

### Topics

- [BlazingText \(algorithm\) \(p. 1273\)](#)
- [Chainer \(DLC\) \(p. 1273\)](#)
- [Clarify \(algorithm\) \(p. 1274\)](#)
- [Data Wrangler \(algorithm\) \(p. 1274\)](#)
- [Debugger \(algorithm\) \(p. 1274\)](#)
- [DeepAR Forecasting \(algorithm\) \(p. 1275\)](#)
- [Factorization Machines \(algorithm\) \(p. 1275\)](#)
- [Hugging Face \(algorithm\) \(p. 1275\)](#)
- [IP Insights \(algorithm\) \(p. 1276\)](#)
- [Image classification \(algorithm\) \(p. 1276\)](#)
- [Inferentia MXNet \(DLC\) \(p. 1276\)](#)

### [BlazingText \(algorithm\)](#)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='blazingtext', region='me-south-1')
```

Registry path	Version	Job types (image scope)		
249704162688.dkr.ecr.me-south-1.amazonaws.com/blazingtext:<tag>		inference, training		

### [Chainer \(DLC\)](#)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='chainer', region='me-south-1', version='5.0.0', py_version='py3', image_scope='inference', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
724002660598.dkr.ecr.me-south-1.amazonaws.com/sagemaker-chainer:<tag>	4.0.0-	inference, training	CPU, GPU	py2, py3
724002660598.dkr.ecr.me-south-1.amazonaws.com/sagemaker-chainer:<tag>	4.1.0-	inference, training	CPU, GPU	py2, py3

Registry path	Version	Job types (image scope)	Processor types	Python versions
724002660598.dkr.ecr.me1.0-south-1.amazonaws.com/sagemaker-chainer:<tag>		inference, training	CPU, GPU	py2, py3

### Clarify (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='clarify', region='me-south-1', version='1.0', image_scope='processing')
```

Registry path	Version	Job types (image scope)		
835444307964.dkr.ecr.me1.0-south-1.amazonaws.com/sagemaker-clarify-processing:<tag>		processing		

### Data Wrangler (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='data-wrangler', region='me-south-1')
```

Registry path	Version	Job types (image scope)		
376037874950.dkr.ecr.me1.x-south-1.amazonaws.com/sagemaker-data-wrangler-container:<tag>		processing		

### Debugger (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='debugger', region='me-south-1')
```

Registry path	Version	Job types (image scope)		
986000313247.dkr.ecr.me1atest-south-1.amazonaws.com/		debugger		

Registry path	Version	Job types (image scope)		
sagemaker-debugger-rules:<tag>				

## DeepAR Forecasting (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='forecasting-deepar', region='us-south-1')
```

Registry path	Version	Job types (image scope)		
249704162688.dkr.ecr.us-south-1.amazonaws.com/forecasting-deepar:<tag>		inference, training		

## Factorization Machines (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='factorization-machines', region='us-south-1')
```

Registry path	Version	Job types (image scope)		
249704162688.dkr.ecr.us-south-1.amazonaws.com/factorization-machines:<tag>		inference, training		

## Hugging Face (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='huggingface', region='us-south-1', version='4.4.2', image_scope='training', base_framework_version='tensorflow2.4.1')
```

Registry path	Version	Job types (image scope)		
217643126080.dkr.ecr.us-south-1.amazonaws.com/huggingface-pytorch-training:<tag>	4.4.2	training		

Registry path	Version	Job types (image scope)		
217643126080.dkr.ecr.me4.5.0 south-1.amazonaws.com/ huggingface-pytorch- training:<tag>		training		
217643126080.dkr.ecr.me4.4.2 south-1.amazonaws.com/ huggingface- tensorflow- training:<tag>		training		
217643126080.dkr.ecr.me4.5.0 south-1.amazonaws.com/ huggingface- tensorflow- training:<tag>		training		

### IP Insights (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='ipinsights', region='me-south-1')
```

Registry path	Version	Job types (image scope)		
249704162688.dkr.ecr.me4 south-1.amazonaws.com/ ipinsights:<tag>		inference, training		

### Image classification (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='image-classification', region='me-south-1')
```

Registry path	Version	Job types (image scope)		
249704162688.dkr.ecr.me4 south-1.amazonaws.com/ image- classification:<tag>		inference, training		

### Inferentia MXNet (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='inferentia-mxnet',region='me-south-1',version='1.5.1',instance_type='ml.inf1.6xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
836785723513.dkr.ecr.me-south-1.amazonaws.com/sagemaker-neo-mxnet:<tag>		inference	inf	py3

### Inferentia PyTorch (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='inferentia-pytorch',region='me-south-1',version='1.5.1',py_version='py3')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
836785723513.dkr.ecr.me-south-1.amazonaws.com/sagemaker-neo-pytorch:<tag>		inference	inf	py3

### K-Means (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='kmeans',region='me-south-1')
```

Registry path	Version	Job types (image scope)		
249704162688.dkr.ecr.me-south-1.amazonaws.com/kmeans:<tag>		inference, training		

### KNN (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='knn',region='me-south-1')
```

Registry path	Version	Job types (image scope)		
249704162688.dkr.ecr.me1 south-1.amazonaws.com/ knn:<tag>		inference, training		

### Linear Learner (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='linear-learner', region='me-south-1')
```

Registry path	Version	Job types (image scope)		
249704162688.dkr.ecr.me1 south-1.amazonaws.com/ linear-learner:<tag>		inference, training		

### MXNet (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='mxnet', region='me-south-1', version='1.4.1', py_version='py3', image_scope='inference',
 instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
217643126080.dkr.ecr.me1-south-1.amazonaws.com/ mxnet-inference-eia:<tag>		eia	CPU	py2, py3
217643126080.dkr.ecr.me1-south-1.amazonaws.com/ mxnet-inference-eia:<tag>		eia	CPU	py2, py3
217643126080.dkr.ecr.me1-south-1.amazonaws.com/ mxnet-inference-eia:<tag>		eia	CPU	py3
217643126080.dkr.ecr.me1-south-1.amazonaws.com/ mxnet-inference:<tag>		inference	CPU, GPU	py3

Registry path	Version	Job types (image scope)	Processor types	Python versions
217643126080.dkr.edr. <del>6.0</del> -south-1.amazonaws.com/mxnet-inference:<tag>		inference	CPU, GPU	py2, py3
217643126080.dkr.edr. <del>7.0</del> -south-1.amazonaws.com/mxnet-inference:<tag>		inference	CPU, GPU	py3
217643126080.dkr.edr. <del>8.0</del> -south-1.amazonaws.com/mxnet-inference:<tag>		inference	CPU, GPU	py37
217643126080.dkr.edr. <del>4.1</del> -south-1.amazonaws.com/mxnet-training:<tag>		training	CPU, GPU	py3
217643126080.dkr.edr. <del>6.0</del> -south-1.amazonaws.com/mxnet-training:<tag>		training	CPU, GPU	py2, py3
217643126080.dkr.edr. <del>7.0</del> -south-1.amazonaws.com/mxnet-training:<tag>		training	CPU, GPU	py3
217643126080.dkr.edr. <del>8.0</del> -south-1.amazonaws.com/mxnet-training:<tag>		training	CPU, GPU	py37
724002660598.dkr.edr. <del>3.0</del> -south-1.amazonaws.com/sagemaker-mxnet-eia:<tag>		eia	CPU	py2, py3
724002660598.dkr.edr. <del>4.0</del> -south-1.amazonaws.com/sagemaker-mxnet-serving-eia:<tag>		eia	CPU	py2, py3
724002660598.dkr.edr. <del>4.0</del> -south-1.amazonaws.com/sagemaker-mxnet-serving:<tag>		inference	CPU, GPU	py2, py3
724002660598.dkr.edr. <del>4.1</del> -south-1.amazonaws.com/sagemaker-mxnet-serving:<tag>		inference	CPU, GPU	py2

Registry path	Version	Job types (image scope)	Processor types	Python versions
724002660598.dkr.edr.12e1-south-1.amazonaws.com/sagemaker-mxnet:<tag>		inference	CPU, GPU	py2, py3
724002660598.dkr.edr.12e1-south-1.amazonaws.com/sagemaker-mxnet:<tag>		training	CPU, GPU	py2, py3
724002660598.dkr.edr.01e-south-1.amazonaws.com/sagemaker-mxnet:<tag>		inference	CPU, GPU	py2, py3
724002660598.dkr.edr.01e-south-1.amazonaws.com/sagemaker-mxnet:<tag>		training	CPU, GPU	py2, py3
724002660598.dkr.edr.11e-south-1.amazonaws.com/sagemaker-mxnet:<tag>		inference	CPU, GPU	py2, py3
724002660598.dkr.edr.11e-south-1.amazonaws.com/sagemaker-mxnet:<tag>		training	CPU, GPU	py2, py3
724002660598.dkr.edr.21e-south-1.amazonaws.com/sagemaker-mxnet:<tag>		inference	CPU, GPU	py2, py3
724002660598.dkr.edr.21e-south-1.amazonaws.com/sagemaker-mxnet:<tag>		training	CPU, GPU	py2, py3
724002660598.dkr.edr.31e-south-1.amazonaws.com/sagemaker-mxnet:<tag>		inference	CPU, GPU	py2, py3
724002660598.dkr.edr.31e-south-1.amazonaws.com/sagemaker-mxnet:<tag>		training	CPU, GPU	py2, py3
724002660598.dkr.edr.41e-south-1.amazonaws.com/sagemaker-mxnet:<tag>		training	CPU, GPU	py2, py3

Registry path	Version	Job types (image scope)	Processor types	Python versions
724002660598.dkr.ecr.me-south-1.amazonaws.com/sagemaker-mxnet:<tag>		training	CPU, GPU	py2

### MXNet Coach (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='coach-mxnet', region='me-south-1', version='0.11', py_version='py3', image_scope='training', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
724002660598.dkr.ecr.me-south-1.amazonaws.com/sagemaker-rl-mxnet:coach0.11-<tag>		training	CPU, GPU	py3
724002660598.dkr.ecr.me-south-1.amazonaws.com/sagemaker-rl-mxnet:coach0.11.0-<tag>		training	CPU, GPU	py3

### Model Monitor (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='model-monitor', region='me-south-1')
```

Registry path	Version	Job types (image scope)		
607024016150.dkr.ecr.me-south-1.amazonaws.com/sagemaker-model-monitor-analyzer:<tag>		monitoring		

### NTM (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
```

```
image_uris.retrieve(framework='ntm', region='me-south-1')
```

Registry path	Version	Job types (image scope)		
249704162688.dkr.ecr.me-south-1.amazonaws.com/ntm:<tag>		inference, training		

### Neo Image Classification (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='image-classification-neo', region='me-south-1')
```

Registry path	Version	Job types (image scope)		
836785723513.dkr.ecr.me-south-1.amazonaws.com/image-classification-neo:<tag>		inference		

### Neo MXNet (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='neo-mxnet', region='me-south-1', version='1.8', py_version='py3', image_scope='inference', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
836785723513.dkr.ecr.me-south-1.amazonaws.com/sagemaker-inference-mxnet:<tag>		inference	CPU, GPU	py3

### Neo PyTorch (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='neo-pytorch', region='me-south-1', version='1.6', image_scope='inference', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
836785723513.dkr.ecr. <del>me-</del> south-1.amazonaws.com/sagemaker-inference-pytorch:<tag>		inference	CPU, GPU	py3
836785723513.dkr.ecr. <del>me-</del> south-1.amazonaws.com/sagemaker-inference-pytorch:<tag>		inference	CPU, GPU	py3
836785723513.dkr.ecr. <del>me-</del> south-1.amazonaws.com/sagemaker-inference-pytorch:<tag>		inference	CPU, GPU	py3

### Neo Tensorflow (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='neo-tensorflow', region='me-south-1', version='1.15.3', py_version='py3', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
836785723513.dkr.ecr. <del>me-</del> south-1.amazonaws.com/sagemaker-inference-tensorflow:<tag>		inference	CPU, GPU	py3

### Neo XGBoost (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='xgboost-neo', region='me-south-1')
```

Registry path	Version	Job types (image scope)		
836785723513.dkr.ecr.melatest.south-1.amazonaws.com/xgboost-neo:<tag>		inference		

## Object Detection (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='object-detection',region='me-south-1')
```

Registry path	Version	Job types (image scope)		
249704162688.dkr.ecr.me1 south-1.amazonaws.com/ object-detection:<tag>		inference, training		

## Object2Vec (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='object2vec',region='me-south-1')
```

Registry path	Version	Job types (image scope)		
249704162688.dkr.ecr.me1 south-1.amazonaws.com/ object2vec:<tag>		inference, training		

## PCA (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='pca',region='me-south-1')
```

Registry path	Version	Job types (image scope)		
249704162688.dkr.ecr.me1 south-1.amazonaws.com/ pca:<tag>		inference, training		

## PyTorch (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='pytorch',region='me-
south-1',version='1.8.0',py_version='py3',image_scope='inference',
instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
217643126080.dkr.edr.31e-south-1.amazonaws.com/pytorch-inference-eia:<tag>		eia	CPU	py3
217643126080.dkr.edr.21e-south-1.amazonaws.com/pytorch-inference:<tag>		inference	CPU, GPU	py2, py3
217643126080.dkr.edr.31e-south-1.amazonaws.com/pytorch-inference:<tag>		inference	CPU, GPU	py2, py3
217643126080.dkr.edr.41e-south-1.amazonaws.com/pytorch-inference:<tag>		inference	CPU, GPU	py3
217643126080.dkr.edr.51e-south-1.amazonaws.com/pytorch-inference:<tag>		inference	CPU, GPU	py3
217643126080.dkr.edr.61e-south-1.amazonaws.com/pytorch-inference:<tag>		inference	CPU, GPU	py3, py36
217643126080.dkr.edr.71e-south-1.amazonaws.com/pytorch-inference:<tag>		inference	CPU, GPU	py3, py36
217643126080.dkr.edr.81e-south-1.amazonaws.com/pytorch-inference:<tag>		inference	CPU, GPU	py3, py36
217643126080.dkr.edr.81b-south-1.amazonaws.com/pytorch-inference:<tag>		inference	CPU, GPU	py3, py36
217643126080.dkr.edr.21e-south-1.amazonaws.com/pytorch-training:<tag>		training	CPU, GPU	py2, py3
217643126080.dkr.edr.31e-south-1.amazonaws.com/pytorch-training:<tag>		training	CPU, GPU	py2, py3

Registry path	Version	Job types (image scope)	Processor types	Python versions
217643126080.dkr.edr.40-south-1.amazonaws.com/pytorch-training:<tag>		training	CPU, GPU	py2, py3
217643126080.dkr.edr.50-south-1.amazonaws.com/pytorch-training:<tag>		training	CPU, GPU	py3
217643126080.dkr.edr.60-south-1.amazonaws.com/pytorch-training:<tag>		training	CPU, GPU	py3, py36
217643126080.dkr.edr.70-south-1.amazonaws.com/pytorch-training:<tag>		training	CPU, GPU	py3, py36
217643126080.dkr.edr.80-south-1.amazonaws.com/pytorch-training:<tag>		training	CPU, GPU	py3, py36

Registry path	Version	Job types (image scope)	Processor types	Python versions
724002660598.dkr.ecr.me-south-1.amazonaws.com/sagemaker-pytorch:<tag>		training	CPU, GPU	py2, py3

### Random Cut Forest (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='randomcutforest',region='me-south-1')
```

Registry path	Version	Job types (image scope)		
249704162688.dkr.ecr.me-south-1.amazonaws.com/randomcutforest:<tag>		inference, training		

### Scikit-learn (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='sklearn',region='me-south-1',version='0.23-1',image_scope='inference')
```

Registry path	Version	Job types (image scope)		
801668240914.dkr.ecr.me0.20.0-south-1.amazonaws.com/sagemaker-scikit-learn:<tag>		inference, training		
801668240914.dkr.ecr.me0.23-1-south-1.amazonaws.com/sagemaker-scikit-learn:<tag>		inference, training		

### Semantic Segmentation (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='semantic-segmentation',region='me-south-1')
```

Registry path	Version	Job types (image scope)		
249704162688.dkr.ecr.me1 south-1.amazonaws.com/ semantic-segmentation:<tag>		inference, training		

## Seq2Seq (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='seq2seq',region='me-south-1')
```

Registry path	Version	Job types (image scope)		
249704162688.dkr.ecr.me1 south-1.amazonaws.com/ seq2seq:<tag>		inference, training		

## Spark (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='spark',region='me-south-1',version='3.0',image_scope='processing')
```

Registry path	Version	Job types (image scope)		
750251592176.dkr.ecr.me2.4 south-1.amazonaws.com/ sagemaker-spark-processing:<tag>		processing		
750251592176.dkr.ecr.me3.0 south-1.amazonaws.com/ sagemaker-spark-processing:<tag>		processing		

## SparkML Serving (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='sparkml-serving',region='me-south-1',version='2.4')
```

Registry path	Version	Job types (image scope)		
801668240914.dkr.ecr.me2.2 south-1.amazonaws.com/ sagemaker-sparkml- serving:<tag>		inference		
801668240914.dkr.ecr.me2.4 south-1.amazonaws.com/ sagemaker-sparkml- serving:<tag>		inference		

### Tensorflow (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='tensorflow', region='me-'
south-1', version='1.12.0', image_scope='inference', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions

### Tensorflow Coach (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='coach-tensorflow', region='me-south-1', version='1.0.0', image_scope='training', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
724002660598.dkr.e0.10e-south-1.amazonaws.com/sagemaker-rl-tensorflow:coach0.10-<tag>		training	CPU, GPU	py3
724002660598.dkr.e0.10e1south-1.amazonaws.com/sagemaker-rl-tensorflow:coach0.10.1-<tag>		training	CPU, GPU	py3
724002660598.dkr.e0.11e-south-1.amazonaws.com/sagemaker-rl-tensorflow:coach0.11-<tag>		training	CPU, GPU	py3
724002660598.dkr.e0.11e0south-1.amazonaws.com/sagemaker-rl-		training	CPU, GPU	py3

Registry path	Version	Job types (image scope)	Processor types	Python versions
tensorflow:coach0.11.0-<tag>				
724002660598.dkr.e0.11e1 south-1.amazonaws.com/ sagemaker-rl- tensorflow:coach0.11.1-<tag>		training	CPU, GPU	py3

### Tensorflow Inference (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='inferentia-tensorflow', region='me-south-1', version='1.15.0', instance_type='ml.inf1.6xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
836785723513.dkr.e0.15e0 south-1.amazonaws.com/ sagemaker-neo- tensorflow:<tag>		inference	inf	py3

### Tensorflow Ray (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='ray-tensorflow', region='me-south-1', version='0.8.5', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
724002660598.dkr.e0.5ne- south-1.amazonaws.com/ sagemaker-rl- tensorflow:ray0.5-<tag>		training	CPU, GPU	py3
724002660598.dkr.e0.5n1- south-1.amazonaws.com/ sagemaker-rl- tensorflow:ray0.5.3-<tag>		training	CPU, GPU	py3
724002660598.dkr.e0.5ne- south-1.amazonaws.com/		training	CPU, GPU	py3

Registry path	Version	Job types (image scope)	Processor types	Python versions
sagemaker-rl-tensorflow:ray0.6-<tag>				
724002660598.dkr.ecr.me0.6.5-south-1.amazonaws.com/sagemaker-rl-tensorflow:ray0.6.5-<tag>	0.6.5	training	CPU, GPU	py3

### XGBoost (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='xgboost', region='me-south-1', version='1.2-1')
```

Registry path	Version	Job types (image scope)		
249704162688.dkr.ecr.me1-south-1.amazonaws.com/xgboost:<tag>		inference, training		
801668240914.dkr.ecr.me0.90-1south-1.amazonaws.com/sagemaker-xgboost:<tag>	0.90-1	inference, training		
801668240914.dkr.ecr.me0.90-2south-1.amazonaws.com/sagemaker-xgboost:<tag>	0.90-2	inference, training		
801668240914.dkr.ecr.me1.0-1south-1.amazonaws.com/sagemaker-xgboost:<tag>	1.0-1	inference, training		
801668240914.dkr.ecr.me1.2-1south-1.amazonaws.com/sagemaker-xgboost:<tag>	1.2-1	inference, training		
801668240914.dkr.ecr.me1.2-2south-1.amazonaws.com/sagemaker-xgboost:<tag>	1.2-2	inference, training		
801668240914.dkr.ecr.me1.3-1south-1.amazonaws.com/sagemaker-xgboost:<tag>	1.3-1	inference, training		

## Docker Registry Paths and Example Code for South America (São Paulo) (sa-east-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

### Topics

## BlazingText (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='blazingtext',region='sa-east-1')
```

Registry path	Version	Job types (image scope)		
855470959533.dkr.ecr.sa-1 east-1.amazonaws.com/ blazingtext:<tag>		inference, training		

## Chainer (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='chainer',region='sa-
east-1',version='5.0.0',py_version='py3',image_scope='inference',instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
520713654638.dkr.e4.60 east-1.amazonaws.com/ sagemaker- chainer:<tag>		inference, training	CPU, GPU	py2, py3
520713654638.dkr.e4.10 east-1.amazonaws.com/ sagemaker- chainer:<tag>		inference, training	CPU, GPU	py2, py3
520713654638.dkr.e5.60 east-1.amazonaws.com/ sagemaker- chainer:<tag>		inference, training	CPU, GPU	py2, py3

## Clarify (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='clarify',region='sa-
east-1',version='1.0',image_scope='processing')
```

Registry path	Version	Job types (image scope)		
520018980103.dkr.ecr.sa-1.0 east-1.amazonaws.com/		processing		

Registry path	Version	Job types (image scope)		
sagemaker-clarify-processing:<tag>				

### Data Wrangler (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='data-wrangler', region='sa-east-1')
```

Registry path	Version	Job types (image scope)		
424196993095.dkr.ecr.sa-east-1.x east-1.amazonaws.com/ sagemaker- data-wrangler- container:<tag>		processing		

### Debugger (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='debugger', region='sa-east-1')
```

Registry path	Version	Job types (image scope)		
818342061345.dkr.ecr.sa-latest east-1.amazonaws.com/ sagemaker-debugger- rules:<tag>		debugger		

### DeepAR Forecasting (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='forecasting-deepar', region='sa-east-1')
```

Registry path	Version	Job types (image scope)		
855470959533.dkr.ecr.sa-1 east-1.amazonaws.com/ forecasting- deepar:<tag>		inference, training		

## Factorization Machines (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='factorization-machines',region='sa-east-1')
```

Registry path	Version	Job types (image scope)		
855470959533.dkr.ecr.sa-1 east-1.amazonaws.com/ factorization- machines:<tag>		inference, training		

## Hugging Face (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='huggingface',region='sa-  
east-1',version='4.4.2',image_scope='training',base_framework_version='tensorflow2.4.1')
```

Registry path	Version	Job types (image scope)		
763104351884.dkr.ecr.sa-4.4.2 east-1.amazonaws.com/ huggingface-pytorch- training:<tag>		training		
763104351884.dkr.ecr.sa-4.5.0 east-1.amazonaws.com/ huggingface-pytorch- training:<tag>		training		
763104351884.dkr.ecr.sa-4.4.2 east-1.amazonaws.com/ huggingface- tensorflow- training:<tag>		training		
763104351884.dkr.ecr.sa-4.5.0 east-1.amazonaws.com/ huggingface- tensorflow- training:<tag>		training		

## IP Insights (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='ipinsights',region='sa-east-1')
```

Registry path	Version	Job types (image scope)		
855470959533.dkr.ecr.sa-1 east-1.amazonaws.com/ ipinsights:<tag>		inference, training		

### Image classification (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='image-classification', region='sa-east-1')
```

Registry path	Version	Job types (image scope)		
855470959533.dkr.ecr.sa-1 east-1.amazonaws.com/ image- classification:<tag>		inference, training		

### Inferentia MXNet (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='inferentia-mxnet', region='sa-  
east-1', version='1.5.1', instance_type='ml.inf1.6xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
756306329178.dkr.ecr.sa-1 east-1.amazonaws.com/ sagemaker-neo- mxnet:<tag>		inference	inf	py3

### Inferentia PyTorch (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='inferentia-pytorch', region='sa-  
east-1', version='1.5.1', py_version='py3')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
756306329178.dkr.ecr.sa-1 east-1.amazonaws.com/		inference	inf	py3

Registry path	Version	Job types (image scope)	Processor types	Python versions
sagemaker-neo-pytorch:<tag>				

## K-Means (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='kmeans',region='sa-east-1')
```

Registry path	Version	Job types (image scope)		
855470959533.dkr.ecr.sa-1 east-1.amazonaws.com/ kmeans:<tag>		inference, training		

## KNN (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='knn',region='sa-east-1')
```

Registry path	Version	Job types (image scope)		
855470959533.dkr.ecr.sa-1 east-1.amazonaws.com/ knn:<tag>		inference, training		

## Linear Learner (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='linear-learner',region='sa-east-1')
```

Registry path	Version	Job types (image scope)		
855470959533.dkr.ecr.sa-1 east-1.amazonaws.com/ linear-learner:<tag>		inference, training		

## MXNet (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='mxnet', region='sa-east-1', version='1.4.1', py_version='py3', image_scope='inference',
instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
520713654638.dkr.e-dr.3@east-1.amazonaws.com/sagemaker-mxnet-eia:<tag>		eia	CPU	py2, py3

763104351884.dkr.e0r.8a0 east-1.amazonaws.com/ mxnet- training:<tag>		training	CPU, GPU	py37

## MXNet Coach (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='coach-mxnet', region='sa-
east-1', version='0.11', py_version='py3', image_scope='training', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
520713654638.dkr.e0r.3a0- east-1.amazonaws.com/ sagemaker-rl- mxnet:coach0.11- <tag>		training	CPU, GPU	py3
520713654638.dkr.e0r.3a0- east-1.amazonaws.com/ sagemaker-rl- mxnet:coach0.11.0- <tag>		training	CPU, GPU	py3

## Model Monitor (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='model-monitor',region='sa-east-1')
```

Registry path	Version	Job types (image scope)		
539772159869.dkr.ecr.sa-east-1.amazonaws.com/ sagemaker-model-monitor-analyzer:<tag>		monitoring		

## NTM (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='ntm',region='sa-east-1')
```

Registry path	Version	Job types (image scope)		
855470959533.dkr.ecr.sa-1 east-1.amazonaws.com/ ntm:<tag>		inference, training		

## Neo Image Classification (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='image-classification-neo',region='sa-east-1')
```

Registry path	Version	Job types (image scope)		
756306329178.dkr.ecr.sa-latest east-1.amazonaws.com/ image-classification-neo:<tag>		inference		

## Neo MXNet (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
```

```
image_uris.retrieve(framework='neo-mxnet', region='sa-east-1', version='1.8', py_version='py3', image_scope='inference', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
756306329178.dkr.e-dr.8a-east-1.amazonaws.com/sagemaker-inference-mxnet:<tag>		inference	CPU, GPU	py3

## Neo PyTorch (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='neo-pytorch', region='sa-east-1', version='1.6', image_scope='inference', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
756306329178.dkr.e-dr.4a-east-1.amazonaws.com/sagemaker-inference-pytorch:<tag>		inference	CPU, GPU	py3
756306329178.dkr.e-dr.5a-east-1.amazonaws.com/sagemaker-inference-pytorch:<tag>		inference	CPU, GPU	py3
756306329178.dkr.e-dr.6a-east-1.amazonaws.com/sagemaker-inference-pytorch:<tag>		inference	CPU, GPU	py3

## Neo Tensorflow (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='neo-tensorflow', region='sa-east-1', version='1.15.3', py_version='py3', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
756306329178.dkr.ecr.sa-1 east-1.amazonaws.com/ sagemaker- inference- tensorflow:<tag>		inference	CPU, GPU	py3

### Neo XGBoost (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='xgboost-neo', region='sa-east-1')
```

Registry path	Version	Job types (image scope)		
756306329178.dkr.ecr.sa-1 east-1.amazonaws.com/ xgboost-neo:<tag>		inference		

### Object Detection (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='object-detection', region='sa-east-1')
```

Registry path	Version	Job types (image scope)		
855470959533.dkr.ecr.sa-1 east-1.amazonaws.com/ object-detection:<tag>		inference, training		

### Object2Vec (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='object2vec', region='sa-east-1')
```

Registry path	Version	Job types (image scope)		
855470959533.dkr.ecr.sa-1 east-1.amazonaws.com/ object2vec:<tag>		inference, training		

## PCA (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='pca', region='sa-east-1')
```

Registry path	Version	Job types (image scope)		
855470959533.dkr.ecr.sa-1 east-1.amazonaws.com/ pca:<tag>		inference, training		

## PyTorch (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='pytorch', region='sa-
east-1', version='1.8.0', py_version='py3', image_scope='inference',
 instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
520713654638.dkr.e0.4@ east-1.amazonaws.com/ sagemaker- pytorch:<tag>		inference	CPU, GPU	py2, py3
520713654638.dkr.e0.4@ east-1.amazonaws.com/ sagemaker- pytorch:<tag>		training	CPU, GPU	py2, py3
520713654638.dkr.e0.6@ east-1.amazonaws.com/ sagemaker- pytorch:<tag>		inference	CPU, GPU	py2, py3
520713654638.dkr.e0.6@ east-1.amazonaws.com/ sagemaker- pytorch:<tag>		training	CPU, GPU	py2, py3
520713654638.dkr.e0.8@ east-1.amazonaws.com/ sagemaker- pytorch:<tag>		inference	CPU, GPU	py2, py3
520713654638.dkr.e0.8@ east-1.amazonaws.com/ sagemaker- pytorch:<tag>		training	CPU, GPU	py2, py3

Registry path	Version	Job types (image scope)	Processor types	Python versions
763104351884.dkr.eif.3a1-east-1.amazonaws.com/pytorch-inference-eia:<tag>		eia	CPU	py3
763104351884.dkr.eif.2a0-east-1.amazonaws.com/pytorch-inference:<tag>		inference	CPU, GPU	py2, py3
763104351884.dkr.eif.3a1-east-1.amazonaws.com/pytorch-inference:<tag>		inference	CPU, GPU	py2, py3
763104351884.dkr.eif.4a0-east-1.amazonaws.com/pytorch-inference:<tag>		inference	CPU, GPU	py3
763104351884.dkr.eif.5a0-east-1.amazonaws.com/pytorch-inference:<tag>		inference	CPU, GPU	py3
763104351884.dkr.eif.6a0-east-1.amazonaws.com/pytorch-inference:<tag>		inference	CPU, GPU	py3, py36
763104351884.dkr.eif.7a1-east-1.amazonaws.com/pytorch-inference:<tag>		inference	CPU, GPU	py3, py36
763104351884.dkr.eif.8a0-east-1.amazonaws.com/pytorch-inference:<tag>		inference	CPU, GPU	py3, py36
763104351884.dkr.eif.8a1-east-1.amazonaws.com/pytorch-inference:<tag>		inference	CPU, GPU	py3, py36
763104351884.dkr.eif.2a0-east-1.amazonaws.com/pytorch-training:<tag>		training	CPU, GPU	py2, py3
763104351884.dkr.eif.3a1-east-1.amazonaws.com/pytorch-training:<tag>		training	CPU, GPU	py2, py3

Registry path	Version	Job types (image scope)	Processor types	Python versions
763104351884.dkr.ecr. <b>40</b> east-1.amazonaws.com/ pytorch- training:<tag>		training	CPU, GPU	py2, py3
763104351884.dkr.ecr. <b>50</b> east-1.amazonaws.com/ pytorch- training:<tag>		training	CPU, GPU	py3
763104351884.dkr.ecr. <b>60</b> east-1.amazonaws.com/ pytorch- training:<tag>		training	CPU, GPU	py3, py36
763104351884.dkr.ecr. <b>70</b> east-1.amazonaws.com/ pytorch- training:<tag>		training	CPU, GPU	py3, py36
763104351884.dkr.ecr. <b>80</b> east-1.amazonaws.com/ pytorch- training:<tag>		training	CPU, GPU	py3, py36
763104351884.dkr.ecr. <b>81</b> east-1.amazonaws.com/ pytorch- training:<tag>		training	CPU, GPU	py3, py36

## Random Cut Forest (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='randomcutforest', region='sa-east-1')
```

Registry path	Version	Job types (image scope)		
855470959533.dkr.ecr.sa-1 east-1.amazonaws.com/ randomcutforest:<tag>		inference, training		

## Scikit-learn (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='sklearn', region='sa-  
east-1', version='0.23-1', image_scope='inference')
```

Registry path	Version	Job types (image scope)		
737474898029.dkr.ecr.sa-east-1.amazonaws.com/sagemaker-scikit-learn:<tag>	0.20.0	inference, training		
737474898029.dkr.ecr.sa-east-1.amazonaws.com/sagemaker-scikit-learn:<tag>	0.23.1	inference, training		

### Semantic Segmentation (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='semantic-segmentation',region='sa-east-1')
```

Registry path	Version	Job types (image scope)		
855470959533.dkr.ecr.sa-east-1.amazonaws.com/semantic-segmentation:<tag>	1	inference, training		

### Seq2Seq (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='seq2seq',region='sa-east-1')
```

Registry path	Version	Job types (image scope)		
855470959533.dkr.ecr.sa-east-1.amazonaws.com/seq2seq:<tag>	1	inference, training		

### Spark (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='spark',region='sa-east-1',version='3.0',image_scope='processing')
```

Registry path	Version	Job types (image scope)		
737130764395.dkr.ecr.sa-east-1.amazonaws.com/sagemaker-spark-processing:<tag>	2.4	processing		
737130764395.dkr.ecr.sa-east-1.amazonaws.com/sagemaker-spark-processing:<tag>	3.0	processing		

## SparkML Serving (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='sparkml-serving', region='sa-east-1', version='2.4')
```

Registry path	Version	Job types (image scope)		
737474898029.dkr.ecr.sa-east-1.amazonaws.com/sagemaker-sparkml-serving:<tag>	2.2	inference		
737474898029.dkr.ecr.sa-east-1.amazonaws.com/sagemaker-sparkml-serving:<tag>	2.4	inference		

## Tensorflow (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='tensorflow', region='sa-east-1', version='1.12.0', image_scope='inference', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
520713654638.dkr.ecr.sa-east-1.amazonaws.com/sagemaker-tensorflow-eia:<tag>		eia	CPU	py2
520713654638.dkr.ecr.sa-east-1.amazonaws.com/sagemaker-		training	CPU, GPU	py2, py3

Registry path	Version	Job types (image scope)	Processor types	Python versions

### Tensorflow Coach (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='coach-tensorflow',region='sa-east-1',version='1.0.0',image_scope='training',instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
520713654638.dkr.e0.10-east-1.amazonaws.com/sagemaker-rl-		training	CPU, GPU	py3

Registry path	Version	Job types (image scope)	Processor types	Python versions
tensorflow:coach0.10-<tag>				
520713654638.dkr.e0.10.1east-1.amazonaws.com/sagemaker-rl-tensorflow:coach0.10.1-<tag>		training	CPU, GPU	py3
520713654638.dkr.e0.11-east-1.amazonaws.com/sagemaker-rl-tensorflow:coach0.11.1-<tag>		training	CPU, GPU	py3
520713654638.dkr.e0.11.0east-1.amazonaws.com/sagemaker-rl-tensorflow:coach0.11.0-<tag>		training	CPU, GPU	py3
520713654638.dkr.e0.11.1east-1.amazonaws.com/sagemaker-rl-tensorflow:coach0.11.1-<tag>		training	CPU, GPU	py3

## Tensorflow Inference (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='inferentia-tensorflow',region='sa-east-1',version='1.15.0',instance_type='ml.inf1.6xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
756306329178.dkr.e0.15.0east-1.amazonaws.com/sagemaker-neo-tensorflow:<tag>		inference	inf	py3

## Tensorflow Ray (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='ray-tensorflow',region='sa-east-1',version='0.8.5',instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
520713654638.dkr.e0.5a-east-1.amazonaws.com/sagemaker-rl-tensorflow:ray0.5-<tag>		training	CPU, GPU	py3
520713654638.dkr.e0.5a-east-1.amazonaws.com/sagemaker-rl-tensorflow:ray0.5.3-<tag>		training	CPU, GPU	py3
520713654638.dkr.e0.6a-east-1.amazonaws.com/sagemaker-rl-tensorflow:ray0.6-<tag>		training	CPU, GPU	py3
520713654638.dkr.e0.6a-east-1.amazonaws.com/sagemaker-rl-tensorflow:ray0.6.5-<tag>		training	CPU, GPU	py3

## XGBoost (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='xgboost',region='sa-east-1',version='1.2-1')
```

Registry path	Version	Job types (image scope)		
737474898029.dkr.ecr.sa-east-1.amazonaws.com/sagemaker-xgboost:<tag>	0.90-1	inference, training		
737474898029.dkr.ecr.sa-east-1.amazonaws.com/sagemaker-xgboost:<tag>	0.90-2	inference, training		
737474898029.dkr.ecr.sa-east-1.amazonaws.com/sagemaker-xgboost:<tag>	1.0-1	inference, training		
737474898029.dkr.ecr.sa-east-1.amazonaws.com/sagemaker-xgboost:<tag>	1.2-1	inference, training		

Registry path	Version	Job types (image scope)		
737474898029.dkr.ecr.sa-east-1.amazonaws.com/sagemaker-xgboost:<tag>	1.2-2	inference, training		
737474898029.dkr.ecr.sa-east-1.amazonaws.com/sagemaker-xgboost:<tag>	1.3-1	inference, training		
855470959533.dkr.ecr.sa-east-1.amazonaws.com/xgboost:<tag>	1	inference, training		

### Docker Registry Paths and Example Code for Amazon GovCloud (US-West) (us-gov-west-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

#### Topics

- [BlazingText \(algorithm\) \(p. 1326\)](#)
- [Chainer \(DLC\) \(p. 1326\)](#)
- [Debugger \(algorithm\) \(p. 1327\)](#)

### [BlazingText \(algorithm\)](#)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='blazingtext', region='us-gov-west-1')
```

Registry path	Version	Job types (image scope)		
226302683700.dkr.ecr.us-1 gov- west-1.amazonaws.com/ blazingtext:<tag>		inference, training		

### [Chainer \(DLC\)](#)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='chainer', region='us-gov-  
west-1', version='5.0.0', py_version='py3', image_scope='inference', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
246785580436.dkr.ecr.us-1 gov- west-1.amazonaws.com/ sagemaker- chainer:<tag>		inference, training	CPU, GPU	py2, py3
246785580436.dkr.ecr.us-1 gov- west-1.amazonaws.com/ sagemaker- chainer:<tag>		inference, training	CPU, GPU	py2, py3
246785580436.dkr.ecr.us-1 gov- west-1.amazonaws.com/		inference, training	CPU, GPU	py2, py3

Registry path	Version	Job types (image scope)	Processor types	Python versions
sagemaker-chainer:<tag>				

### Debugger (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='debugger', region='us-gov-west-1')
```

Registry path	Version	Job types (image scope)		
515509971035.dkr.ecr.us-latest gov-west-1.amazonaws.com/ sagemaker-debugger-rules:<tag>		debugger		

### DeepAR Forecasting (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='forecasting-deepar', region='us-gov-west-1')
```

Registry path	Version	Job types (image scope)		
226302683700.dkr.ecr.us-1 gov-west-1.amazonaws.com/ forecasting-deepar:<tag>		inference, training		

### Factorization Machines (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='factorization-machines', region='us-gov-west-1')
```

Registry path	Version	Job types (image scope)		
226302683700.dkr.ecr.us-1 gov-west-1.amazonaws.com/		inference, training		

Registry path	Version	Job types (image scope)		
factorization-machines:<tag>				

### Hugging Face (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='huggingface', region='us-gov-west-1', version='4.4.2', image_scope='training', base_framework_version='tensorflow2.4.1')
```

Registry path	Version	Job types (image scope)		
442386744353.dkr.ecr.us-4.4.2.gov-west-1.amazonaws.com/huggingface-pytorch-training:<tag>		training		
442386744353.dkr.ecr.us-4.5.0.gov-west-1.amazonaws.com/huggingface-pytorch-training:<tag>		training		
442386744353.dkr.ecr.us-4.4.2.gov-west-1.amazonaws.com/huggingface-tensorflow-training:<tag>		training		
442386744353.dkr.ecr.us-4.5.0.gov-west-1.amazonaws.com/huggingface-tensorflow-training:<tag>		training		

### IP Insights (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='ipinsights', region='us-gov-west-1')
```

Registry path	Version	Job types (image scope)		
226302683700.dkr.ecr.us-1.gov-		inference, training		

Registry path	Version	Job types (image scope)		
west-1.amazonaws.com/ ipinsights:<tag>				

### Image classification (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='image-classification', region='us-gov-west-1')
```

Registry path	Version	Job types (image scope)		
226302683700.dkr.ecr.us-1 gov- west-1.amazonaws.com/ image- classification:<tag>		inference, training		

### Inferentia MXNet (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='inferentia-mxnet', region='us-gov-  
west-1', version='1.5.1', instance_type='ml.inf1.6xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
263933020539.dkr.ecr.us-1 gov- west-1.amazonaws.com/ sagemaker-neo- mxnet:<tag>		inference	inf	py3

### Inferentia PyTorch (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='inferentia-pytorch', region='us-gov-  
west-1', version='1.5.1', py_version='py3')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
263933020539.dkr.ecr.us-1 gov-		inference	inf	py3

Registry path	Version	Job types (image scope)	Processor types	Python versions
west-1.amazonaws.com/ sagemaker-neo- pytorch:<tag>				

### K-Means (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='kmeans', region='us-gov-west-1')
```

Registry path	Version	Job types (image scope)		
226302683700.dkr.ecr.us-1 gov- west-1.amazonaws.com/ kmeans:<tag>		inference, training		

### KNN (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='knn', region='us-gov-west-1')
```

Registry path	Version	Job types (image scope)		
226302683700.dkr.ecr.us-1 gov- west-1.amazonaws.com/ knn:<tag>		inference, training		

### LDA (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='lda', region='us-gov-west-1')
```

Registry path	Version	Job types (image scope)		
226302683700.dkr.ecr.us-1 gov- west-1.amazonaws.com/ lda:<tag>		inference, training		

## Linear Learner (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='linear-learner', region='us-gov-west-1')
```

Registry path	Version	Job types (image scope)		
226302683700.dkr.ecr.us-1 gov-west-1.amazonaws.com/ linear-learner:<tag>		inference, training		

## MXNet (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='mxnet', region='us-gov-west-1', version='1.4.1', py_version='py3', image_scope='inference',
 instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
246785580436.dkr.ecr.us-1 gov-west-1.amazonaws.com/ sagemaker-mxnet-eia:<tag>		eia	CPU	py2, py3
246785580436.dkr.ecr.us-1 gov-west-1.amazonaws.com/ sagemaker-mxnet-serving-eia:<tag>		eia	CPU	py2, py3
246785580436.dkr.ecr.us-1 gov-west-1.amazonaws.com/ sagemaker-mxnet-serving:<tag>		inference	CPU, GPU	py2, py3
246785580436.dkr.ecr.us-1 gov-west-1.amazonaws.com/ sagemaker-mxnet-serving:<tag>		inference	CPU, GPU	py2
246785580436.dkr.ecr.us-1 gov-west-1.amazonaws.com/ sagemaker-mxnet:<tag>		inference	CPU, GPU	py2, py3

Registry path	Version	Job types (image scope)	Processor types	Python versions

## MXNet Coach (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='coach-mxnet', region='us-gov-west-1', version='0.11', py_version='py3', image_scope='training', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
246785580436.dkr.e0r.11\$-gov-west-1.amazonaws.com/sagemaker-rl-mxnet:coach0.11-<tag>		training	CPU, GPU	py3
246785580436.dkr.e0r.11.0\$-gov-west-1.amazonaws.com/sagemaker-rl-mxnet:coach0.11.0-<tag>		training	CPU, GPU	py3

## NTM (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='ntm', region='us-gov-west-1')
```

Registry path	Version	Job types (image scope)		
226302683700.dkr.ecr.us-1 gov- west-1.amazonaws.com/ ntm:<tag>		inference, training		

### Neo Image Classification (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='image-classification-neo', region='us-gov-west-1')
```

Registry path	Version	Job types (image scope)		
263933020539.dkr.ecr.us-latest gov- west-1.amazonaws.com/ image-classification- neo:<tag>		inference		

### Neo MXNet (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='neo-mxnet', region='us-gov-  
west-1', version='1.8', py_version='py3', image_scope='inference',  
instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
263933020539.dkr.ecr.us- gov- west-1.amazonaws.com/ sagemaker- inference- mxnet:<tag>		inference	CPU, GPU	py3

### Neo PyTorch (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='neo-pytorch', region='us-gov-west-1', version='1.6', image_scope='inference', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
263933020539.dkr.ecr.us-gov-west-1.amazonaws.com/sagemaker-inference-pytorch:<tag>		inference	CPU, GPU	py3
263933020539.dkr.ecr.us-gov-west-1.amazonaws.com/sagemaker-inference-pytorch:<tag>		inference	CPU, GPU	py3
263933020539.dkr.ecr.us-gov-west-1.amazonaws.com/sagemaker-inference-pytorch:<tag>		inference	CPU, GPU	py3

## Neo Tensorflow (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='neo-tensorflow', region='us-gov-west-1', version='1.15.3', py_version='py3', instance_type='ml.c5.4xlarge')
```

Registry path	Version	Job types (image scope)	Processor types	Python versions
263933020539.dkr.ecr.us-gov-west-1.amazonaws.com/sagemaker-inference-tensorflow:<tag>		inference	CPU, GPU	py3

## Neo XGBoost (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='xgboost-neo', region='us-gov-west-1')
```

<b>Registry path</b>	<b>Version</b>	<b>Job types (image scope)</b>		
263933020539.dkr.ecr.us-west-1.amazonaws.com/xgboost-neo:<tag>		inference		

## Object Detection (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='object-detection', region='us-gov-west-1')
```

<b>Registry path</b>	<b>Version</b>	<b>Job types (image scope)</b>		
226302683700.dkr.ecr.us-west-1.amazonaws.com/object-detection:<tag>		inference, training		

## Object2Vec (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='object2vec', region='us-gov-west-1')
```

<b>Registry path</b>	<b>Version</b>	<b>Job types (image scope)</b>		
226302683700.dkr.ecr.us-west-1.amazonaws.com/object2vec:<tag>		inference, training		

## PCA (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='pca', region='us-gov-west-1')
```

<b>Registry path</b>	<b>Version</b>	<b>Job types (image scope)</b>		
226302683700.dkr.ecr.us-west-1.amazonaws.com/pca		inference, training		

Registry path	Version	Job types (image scope)		
west-1.amazonaws.com/pca:<tag>				

## PyTorch (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='pytorch', region='us-gov-west-1', version='1.8.0', py_version='py3', image_scope='inference',
instance_type='ml.c5.4xlarge')
```

### Random Cut Forest (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='randomcutforest', region='us-gov-west-1')
```

Registry path	Version	Job types (image scope)		
226302683700.dkr.ecr.us-1gov-		inference, training		

Registry path	Version	Job types (image scope)		
west-1.amazonaws.com/randomcutforest:<tag>				

### Scikit-learn (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='sklearn',region='us-gov-west-1',version='0.23-1',image_scope='inference')
```

Registry path	Version	Job types (image scope)		
414596584902.dkr.ecr.us-0.20.0 gov-west-1.amazonaws.com/ sagemaker-scikit-learn:<tag>		inference, training		
414596584902.dkr.ecr.us-0.23-1 gov-west-1.amazonaws.com/ sagemaker-scikit-learn:<tag>		inference, training		

### Semantic Segmentation (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='semantic-segmentation',region='us-gov-west-1')
```

Registry path	Version	Job types (image scope)		
226302683700.dkr.ecr.us-1 gov-west-1.amazonaws.com/ semantic-segmentation:<tag>		inference, training		

### Seq2Seq (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='seq2seq',region='us-gov-west-1')
```

Registry path	Version	Job types (image scope)		
226302683700.dkr.ecr.us-1 gov-west-1.amazonaws.com/ seq2seq:<tag>		inference, training		

## Spark (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='spark', region='us-gov-west-1', version='3.0', image_scope='processing')
```

Registry path	Version	Job types (image scope)		
271483468897.dkr.ecr.us-2.4 gov-west-1.amazonaws.com/ sagemaker-spark-processing:<tag>		processing		
271483468897.dkr.ecr.us-3.0 gov-west-1.amazonaws.com/ sagemaker-spark-processing:<tag>		processing		

## SparkML Serving (algorithm)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='sparkml-serving', region='us-gov-west-1', version='2.4')
```

Registry path	Version	Job types (image scope)		
414596584902.dkr.ecr.us-2.2 gov-west-1.amazonaws.com/ sagemaker-sparkml-serving:<tag>		inference		
414596584902.dkr.ecr.us-2.4 gov-west-1.amazonaws.com/ sagemaker-sparkml-serving:<tag>		inference		

## Tensorflow (DLC)

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='tensorflow', region='us-gov-west-1', version='1.12.0', image_scope='inference', instance_type='ml.c5.4xlarge')
```

## Common Data Formats for Built-in Algorithms

The following topics explain the data formats for the algorithms provided by Amazon SageMaker.

### Topics

- [Common Data Formats for Training \(p. 1354\)](#)
- [Common Data Formats for Inference \(p. 1358\)](#)

### Common Data Formats for Training

To prepare for training, you can preprocess your data using a variety of Amazon services, including Amazon Glue, Amazon EMR, Amazon Redshift, Amazon Relational Database Service, and Amazon Athena. After preprocessing, publish the data to an Amazon S3 bucket. For training, the data need to go through a series of conversions and transformations, including:

- Training data serialization (handled by you)
- Training data deserialization (handled by the algorithm)
- Training model serialization (handled by the algorithm)
- Trained model deserialization (optional, handled by you)

When using Amazon SageMaker in the training portion of the algorithm, make sure to upload all data at once. If more data is added to that location, a new training call would need to be made to construct a brand new model.

### Topics

- [Content Types Supported by Built-In Algorithms \(p. 1355\)](#)
- [Using Pipe Mode \(p. 1355\)](#)
- [Using CSV Format \(p. 1355\)](#)
- [Using RecordIO Format \(p. 1356\)](#)
- [Trained Model Deserialization \(p. 1358\)](#)

## Content Types Supported by Built-In Algorithms

The following table lists some of the commonly supported `ContentType` values and the algorithms that use them:

### ContentTypes for Built-in Algorithms

ContentType	Algorithm
application/x-image	Object Detection Algorithm, Semantic Segmentation
application/x-recordio	Object Detection Algorithm
application/x-recordio-protobuf	Factorization Machines, K-Means, k-NN, Latent Dirichlet Allocation, Linear Learner, NTM, PCA, RCF, Sequence-to-Sequence
application/jsonlines	BlazingText, DeepAR
image/jpeg	Object Detection Algorithm, Semantic Segmentation
image/png	Object Detection Algorithm, Semantic Segmentation
text/csv	IP Insights, K-Means, k-NN, Latent Dirichlet Allocation, Linear Learner, NTM, PCA, RCF, XGBoost
text/libsvm	XGBoost

For a summary of the parameters used by each algorithm, see the documentation for the individual algorithms or this [table](#).

### Using Pipe Mode

In *Pipe mode*, your training job streams data directly from Amazon Simple Storage Service (Amazon S3). Streaming can provide faster start times for training jobs and better throughput. This is in contrast to *File mode*, in which your data from Amazon S3 is stored on the training instance volumes. File mode uses disk space to store both your final model artifacts and your full training dataset. By streaming in your data directly from Amazon S3 in Pipe mode, you reduce the size of Amazon Elastic Block Store volumes of your training instances. Pipe mode needs only enough disk space to store your final model artifacts. See the [AlgorithmSpecification](#) for additional details on the training input mode.

### Using CSV Format

Many Amazon SageMaker algorithms support training with data in CSV format. To use data in CSV format for training, in the input data channel specification, specify `text/csv` as the `ContentType`. Amazon SageMaker requires that a CSV file does not have a header record and that the target variable is in the first column. To run unsupervised learning algorithms that don't have a target, specify the number of label columns in the content type. For example, in this case '`content_type=text/csv;label_size=0`'. For a notebook example that uses CSV format, see [Breast Cancer Prediction](#). For more information, see [Now use Pipe mode with CSV datasets for faster training on Amazon SageMaker built-in algorithms](#).

## Using RecordIO Format

In the protobuf recordIO format, SageMaker converts each observation in the dataset into a binary representation as a set of 4-byte floats, then loads it in the protobuf values field. If you are using Python for your data preparation, we strongly recommend that you use these existing transformations. However, if you are using another language, the protobuf definition file below provides the schema that you use to convert your data into SageMaker protobuf format.

**Note**

For an example that shows how to convert the commonly used numpy array into the protobuf recordIO format, see [An Introduction to Factorization Machines with MNIST](#).

```
syntax = "proto2";

package aialgs.data;

option java_package = "com.amazonaws.aialgorithms.proto";
option java_outer_classname = "RecordProtos";

// A sparse or dense rank-R tensor that stores data as doubles (float64).
message Float32Tensor {
    // Each value in the vector. If keys is empty, this is treated as a
    // dense vector.
    repeated float values = 1 [packed = true];

    // If key is not empty, the vector is treated as sparse, with
    // each key specifying the location of the value in the sparse vector.
    repeated uint64 keys = 2 [packed = true];

    // An optional shape that allows the vector to represent a matrix.
    // For example, if shape = [ 10, 20 ], floor(keys[i] / 20) gives the row,
    // and keys[i] % 20 gives the column.
    // This also supports n-dimensional tensors.
    // Note: If the tensor is sparse, you must specify this value.
    repeated uint64 shape = 3 [packed = true];
}

// A sparse or dense rank-R tensor that stores data as doubles (float64).
message Float64Tensor {
    // Each value in the vector. If keys is empty, this is treated as a
    // dense vector.
    repeated double values = 1 [packed = true];

    // If this is not empty, the vector is treated as sparse, with
    // each key specifying the location of the value in the sparse vector.
    repeated uint64 keys = 2 [packed = true];

    // An optional shape that allows the vector to represent a matrix.
    // For example, if shape = [ 10, 20 ], floor(keys[i] / 10) gives the row,
    // and keys[i] % 20 gives the column.
    // This also supports n-dimensional tensors.
    // Note: If the tensor is sparse, you must specify this value.
    repeated uint64 shape = 3 [packed = true];
}

// A sparse or dense rank-R tensor that stores data as 32-bit ints (int32).
message Int32Tensor {
    // Each value in the vector. If keys is empty, this is treated as a
    // dense vector.
    repeated int32 values = 1 [packed = true];

    // If this is not empty, the vector is treated as sparse with
    // each key specifying the location of the value in the sparse vector.
    repeated uint64 keys = 2 [packed = true];
```

```

// An optional shape that allows the vector to represent a matrix.
// For example, if shape = [ 10, 20 ], floor(keys[i] / 10) gives the row,
// and keys[i] % 20 gives the column.
// This also supports n-dimensional tensors.
// Note: If the tensor is sparse, you must specify this value.
repeated uint64 shape = 3 [packed = true];
}

// Support for storing binary data for parsing in other ways (such as JPEG/etc).
// This is an example of another type of value and may not immediately be supported.
message Bytes {
    repeated bytes value = 1;

    // If the content type of the data is known, stores it.
    // This allows for the possibility of using decoders for common formats
    // in the future.
    optional string content_type = 2;
}

message Value {
    oneof value {
        // The numbering assumes the possible use of:
        // - float16, float128
        // - int8, int16, int32
        Float32Tensor float32_tensor = 2;
        Float64Tensor float64_tensor = 3;
        Int32Tensor int32_tensor = 7;
        Bytes bytes = 9;
    }
}

message Record {
    // Map from the name of the feature to the value.
    //
    // For vectors and libsvm-like datasets,
    // a single feature with the name `values`
    // should be specified.
    map<string, Value> features = 1;

    // An optional set of labels for this record.
    // Similar to the features field above, the key used for
    // generic scalar / vector labels should be 'values'.
    map<string, Value> label = 2;

    // A unique identifier for this record in the dataset.
    //
    // Whilst not necessary, this allows better
    // debugging where there are data issues.
    //
    // This is not used by the algorithm directly.
    optional string uid = 3;

    // Textual metadata describing the record.
    //
    // This may include JSON-serialized information
    // about the source of the record.
    //
    // This is not used by the algorithm directly.
    optional string metadata = 4;

    // An optional serialized JSON object that allows per-record
    // hyper-parameters/configuration/other information to be set.
    //
    // The meaning/interpretation of this field is defined by
    // the algorithm author and may not be supported.
    //
}

```

```
// This is used to pass additional inference configuration
// when batch inference is used (e.g. types of scores to return).
optional string configuration = 5;
}
```

After creating the protocol buffer, store it in an Amazon S3 location that Amazon SageMaker can access and that can be passed as part of `InputDataConfig` in `create_training_job`.

**Note**

For all Amazon SageMaker algorithms, the `ChannelName` in `InputDataConfig` must be set to `train`. Some algorithms also support a validation or test input channels. These are typically used to evaluate the model's performance by using a hold-out dataset. Hold-out datasets are not used in the initial training but can be used to further tune the model.

## Trained Model Deserialization

Amazon SageMaker models are stored as `model.tar.gz` in the S3 bucket specified in `OutputDataConfig.S3OutputPath` parameter of the `create_training_job` call. You can specify most of these model artifacts when creating a hosting model. You can also open and review them in your notebook instance. When `model.tar.gz` is untarred, it contains `model_algo-1`, which is a serialized Apache MXNet object. For example, you use the following to load the k-means model into memory and view it:

```
import mxnet as mx
print(mx.ndarray.load('model_algo-1'))
```

## Common Data Formats for Inference

Amazon SageMaker algorithms accept and produce several different MIME types for the HTTP payloads used in retrieving online and mini-batch predictions. You can use various Amazon services to transform or preprocess records prior to running inference. At a minimum, you need to convert the data for the following:

- Inference request serialization (handled by you)
- Inference request deserialization (handled by the algorithm)
- Inference response serialization (handled by the algorithm)
- Inference response deserialization (handled by you)

### Topics

- [Convert Data for Inference Request Serialization \(p. 1358\)](#)
- [Convert Data for Inference Response Deserialization \(p. 1359\)](#)
- [Common Request Formats for All Algorithms \(p. 1361\)](#)
- [Use Batch Transform with Built-in Algorithms \(p. 1362\)](#)

## Convert Data for Inference Request Serialization

Content type options for Amazon SageMaker algorithm inference requests include: `text/csv`, `application/json`, and `application/x-recordio-protobuf`. Algorithms that don't support all of these types can support other types. XGBoost, for example, only supports `text/csv` from this list, but also supports `text/libsvm`.

For `text/csv`, the value for the `Body` argument to `invoke_endpoint` should be a string with commas separating the values for each feature. For example, a record for a model with four features might look like `1.5,16.0,14,23.0`. Any transformations performed on the training data should also be performed on the data before obtaining inference. The order of the features matters and must remain unchanged.

`application/json` is significantly more flexible and provides multiple possible formats for developers to use in their applications. At a high level, in JavaScript, the payload might look like the following:

```
let request = {
    // Instances might contain multiple rows that predictions are sought for.
    "instances": [
        {
            // Request and algorithm specific inference parameters.
            "configuration": {},
            // Data in the specific format required by the algorithm.
            "data": {
                "<field name>": dataElement
            }
        }
    ]
}
```

You have the following options for specifying the `dataElement`:

#### Protocol buffers equivalent

```
// Has the same format as the protocol buffers implementation described for training.
let dataElement = {
    "keys": [],
    "values": [],
    "shape": []
}
```

#### Simple numeric vector

```
// An array containing numeric values is treated as an instance containing a
// single dense vector.
let dataElement = [1.5, 16.0, 14.0, 23.0]

// It will be converted to the following representation by the SDK.
let converted = {
    "features": {
        "values": dataElement
    }
}
```

#### For multiple records

```
let request = {
    "instances": [
        // First instance.
        {
            "features": [ 1.5, 16.0, 14.0, 23.0 ]
        },
        // Second instance.
        {
            "features": [ -2.0, 100.2, 15.2, 9.2 ]
        }
    ]
}
```

#### Convert Data for Inference Response Deserialization

Amazon SageMaker algorithms return JSON in several layouts. At a high level, the structure is:

```
let response = {
```

```

    "predictions": [
        // Fields in the response object are defined on a per algorithm-basis.
    ]
}

```

The fields that are included in predictions differ across algorithms. The following are examples of output for the k-means algorithm.

### Single-record inference

```

let response = {
    "predictions": [
        {
            "closest_cluster": 5,
            "distance_to_cluster": 36.5
        }
    ]
}

```

### Multi-record inference

```

let response = {
    "predictions": [
        // First instance prediction.
        {
            "closest_cluster": 5,
            "distance_to_cluster": 36.5
        },
        // Second instance prediction.
        {
            "closest_cluster": 2,
            "distance_to_cluster": 90.3
        }
    ]
}

```

### Multi-record inference with protobuf input

```

{
    "features": [],
    "label": {
        "closest_cluster": {
            "values": [ 5.0 ] // e.g. the closest centroid/cluster was 1.0
        },
        "distance_to_cluster": {
            "values": [ 36.5 ]
        }
    },
    "uid": "abc123",
    "metadata": "{ \"created_at\": '2017-06-03' }"
}

```

SageMaker algorithms also support the JSONLINES format, where the per-record response content is same as that in JSON format. The multi-record structure is a concatenation of per-record response objects separated by newline characters. The response content for the built-in KMeans algorithm for 2 input data points is:

```

{"distance_to_cluster": 23.40593910217285, "closest_cluster": 0.0}
{"distance_to_cluster": 27.250282287597656, "closest_cluster": 0.0}

```

While running batch transform, we recommended using the jsonlines response type by setting the Accept field in the CreateTransformJobRequest to application/jsonlines.

## Common Request Formats for All Algorithms

Most algorithms use several of the following inference request formats.

### JSON Request Format

**Content type:** application/JSON

#### Dense format

```
let request = {
    "instances": [
        {
            "features": [1.5, 16.0, 14.0, 23.0]
        }
    ]
}

let request = {
    "instances": [
        {
            "data": {
                "features": {
                    "values": [ 1.5, 16.0, 14.0, 23.0]
                }
            }
        }
    ]
}
```

#### Sparse format

```
{
    "instances": [
        {"data": {"features": {
            "keys": [26, 182, 232, 243, 431],
            "shape": [2000],
            "values": [1, 1, 1, 4, 1]
        }}
        },
        {"data": {"features": {
            "keys": [0, 182, 232, 243, 431],
            "shape": [2000],
            "values": [13, 1, 1, 4, 1]
        }}
        },
        ...
    ]
}
```

### JSONLINES Request Format

**Content type:** application/JSONLINES

#### Dense format

A single record in dense format can be represented as either:

```
{ "features": [1.5, 16.0, 14.0, 23.0] }
```

or:

```
{ "data": { "features": { "values": [ 1.5, 16.0, 14.0, 23.0] } } }
```

### Sparse Format

A single record in sparse format is represented as:

```
{"data": {"features": { "keys": [26, 182, 232, 243, 431], "shape": [2000], "values": [1, 1, 1, 4, 1] } } }
```

Multiple records are represented as a concatenation of the above single-record representations, separated by newline characters:

```
{"data": {"features": { "keys": [0, 1, 3], "shape": [4], "values": [1, 4, 1] } } }
{"data": {"features": { "values": [ 1.5, 16.0, 14.0, 23.0] } }
{ "features": [1.5, 16.0, 14.0, 23.0] }
```

### CSV Request Format

**Content type:** text/CSV; label\_size=0

#### Note

CSV support is not available for factorization machines.

### RECORDIO Request Format

Content type: application/x-recordio-protobuf

### Use Batch Transform with Built-in Algorithms

While running batch transform, we recommended using the JSONLINES response type instead of JSON, if supported by the algorithm. This is accomplished by setting the `Accept` field in the `CreateTransformJobRequest` to `application/jsonlines`.

When you create a transform job, the `SplitType` must be set according to the `ContentType` of the input data. Similarly, depending on the `Accept` field in the `CreateTransformJobRequest`, `AssembleWith` must be set accordingly. Please use the following table to help appropriately set these fields:

ContentType	Recommended SplitType
application/x-recordio-protobuf	RecordIO
text/csv	Line
application/jsonlines	Line
application/json	None
application/x-image	None
image/*	None
Accept	Recommended AssembleWith
application/x-recordio-protobuf	None
application/json	None
application/jsonlines	Line

For more information on response formats for specific algorithms, see the following:

## Instance Types for Built-in Algorithms

For training and hosting Amazon SageMaker algorithms, we recommend using the following Amazon EC2 instance types:

- ml.m5.xlarge, ml.m5.4xlarge, and ml.m5.10xlarge
- ml.c5.xlarge, ml.c5.2xlarge, and ml.c5.8xlarge
- ml.p3.xlarge, ml.p3.8xlarge, and ml.p3.16xlarge

Most Amazon SageMaker algorithms have been engineered to take advantage of GPU computing for training. Despite higher per-instance costs, GPUs train more quickly, making them more cost effective. Exceptions are noted in this guide.

The size and type of data can have a great effect on which hardware configuration is most effective. When the same model is trained on a recurring basis, initial testing across a spectrum of instance types can discover configurations that are more cost-effective in the long run. Additionally, algorithms that train most efficiently on GPUs might not require GPUs for efficient inference. Experiment to determine the most cost effectiveness solution.

For more information on SageMaker hardware specifications, see [Amazon SageMaker ML Instance Types](#).

## Logs for Built-in Algorithms

Amazon SageMaker algorithms produce Amazon CloudWatch logs, which provide detailed information on the training process. To see the logs, in the Amazon management console, choose **CloudWatch**, choose **Logs**, and then choose the `/aws/sagemaker/TrainingJobs` **log group**. Each training job has one log stream per node on which it was trained. The log stream's name begins with the value specified in the `TrainingJobName` parameter when the job was created.

### Note

If a job fails and logs do not appear in CloudWatch, it's likely that an error occurred before the start of training. Reasons include specifying the wrong training image or S3 location.

The contents of logs vary by algorithms. However, you can typically find the following information:

- Confirmation of arguments provided at the beginning of the log
- Errors that occurred during training
- Measurement of an algorithm's accuracy or numerical performance
- Timings for the algorithm and any major stages within the algorithm

## Common Errors

If a training job fails, some details about the failure are provided by the `FailureReason` return value in the training job description, as follows:

```
sage = boto3.client('sagemaker')
sage.describe_training_job(TrainingJobName=job_name)[ 'FailureReason' ]
```

Others are reported only in the CloudWatch logs. Common errors include the following:

1. Misspecifying a hyperparameter or specifying a hyperparameter that is invalid for the algorithm.

### From the CloudWatch Log

```
[10/16/2017 23:45:17 ERROR 139623806805824 train.py:48]
Additional properties are not allowed (u'mini_batch_size' was
unexpected)
```

2. Specifying an invalid value for a hyperparameter.

### FailureReason

```
AlgorithmError: u'abc' is not valid under any of the given
schemas\n\nFailed validating u'oneOf' in
schema[u'properties'][u'feature_dim']:\n    {u'oneOf':
[ {u'pattern': u'^([1-9][0-9]*)$', u'type': u'string'},\n     {u'minimum': 1, u'type': u'integer'}]}\\
```

### FailureReason

```
[10/16/2017 23:57:17 ERROR 140373086025536 train.py:48] u'abc'
is not valid under any of the given schemas
```

3. Inaccurate protobuf file format.

### From the CloudWatch log

```
[10/17/2017 18:01:04 ERROR 140234860816192 train.py:48] cannot
copy sequence with size 785 to array axis with dimension 784
```

## BlazingText algorithm

The Amazon SageMaker BlazingText algorithm provides highly optimized implementations of the Word2vec and text classification algorithms. The Word2vec algorithm is useful for many downstream natural language processing (NLP) tasks, such as sentiment analysis, named entity recognition, machine translation, etc. Text classification is an important task for applications that perform web searches, information retrieval, ranking, and document classification.

The Word2vec algorithm maps words to high-quality distributed vectors. The resulting vector representation of a word is called a *word embedding*. Words that are semantically similar correspond to vectors that are close together. That way, word embeddings capture the semantic relationships between words.

Many natural language processing (NLP) applications learn word embeddings by training on large collections of documents. These pretrained vector representations provide information about semantics and word distributions that typically improves the generalizability of other models that are later trained

on a more limited amount of data. Most implementations of the Word2vec algorithm are not optimized for multi-core CPU architectures. This makes it difficult to scale to large datasets.

With the BlazingText algorithm, you can scale to large datasets easily. Similar to Word2vec, it provides the Skip-gram and continuous bag-of-words (CBOW) training architectures. BlazingText's implementation of the supervised multi-class, multi-label text classification algorithm extends the fastText text classifier to use GPU acceleration with custom [CUDA](#) kernels. You can train a model on more than a billion words in a couple of minutes using a multi-core CPU or a GPU. And, you achieve performance on par with the state-of-the-art deep learning text classification algorithms.

The BlazingText algorithm is not parallelizable. For more information on parameters related to training, see [Docker Registry Paths for SageMaker Built-in Algorithms](#).

The SageMaker BlazingText algorithms provides the following features:

- Accelerated training of the fastText text classifier on multi-core CPUs or a GPU and Word2Vec on GPUs using highly optimized CUDA kernels. For more information, see [BlazingText: Scaling and Accelerating Word2Vec using Multiple GPUs](#).
- **Enriched Word Vectors with Subword Information** by learning vector representations for character n-grams. This approach enables BlazingText to generate meaningful vectors for out-of-vocabulary (OOV) words by representing their vectors as the sum of the character n-gram (subword) vectors.
- A `batch_skipgram` mode for the Word2Vec algorithm that allows faster training and distributed computation across multiple CPU nodes. The `batch_skipgram` mode does mini-batching using the Negative Sample Sharing strategy to convert level-1 BLAS operations into level-3 BLAS operations. This efficiently leverages the multiply-add instructions of modern architectures. For more information, see [Parallelizing Word2Vec in Shared and Distributed Memory](#).

To summarize, the following modes are supported by BlazingText on different types instances:

Modes	Word2Vec (Unsupervised Learning)	Text Classification (Supervised Learning)
Single CPU instance	cbow  Skip-gram  Batch Skip-gram	supervised
Single GPU instance (with 1 or more GPUs)	cbow  Skip-gram	supervised with one GPU
Multiple CPU instances	Batch Skip-gram	None

For more information about the mathematics behind BlazingText, see [BlazingText: Scaling and Accelerating Word2Vec using Multiple GPUs](#).

### Topics

- [Input/Output Interface for the BlazingText Algorithm \(p. 1366\)](#)
- [EC2 Instance Recommendation for the BlazingText Algorithm \(p. 1368\)](#)

- [BlazingText Hyperparameters \(p. 1369\)](#)
- [Tune a BlazingText Model \(p. 1373\)](#)

## Input/Output Interface for the BlazingText Algorithm

The BlazingText algorithm expects a single preprocessed text file with space-separated tokens. Each line in the file should contain a single sentence. If you need to train on multiple text files, concatenate them into one file and upload the file in the respective channel.

### Training and Validation Data Format

#### Training and Validation Data Format for the Word2Vec Algorithm

For Word2Vec training, upload the file under the *train* channel. No other channels are supported. The file should contain a training sentence per line.

#### Training and Validation Data Format for the Text Classification Algorithm

For supervised mode, you can train with file mode or with the augmented manifest text format.

##### Train with File Mode

For supervised mode, the training/validation file should contain a training sentence per line along with the labels. Labels are words that are prefixed by the string `__label__`. Here is an example of a training/validation file:

```
__label__4 linux ready for prime time , intel says , despite all the linux hype , the
open-source movement has yet to make a huge splash in the desktop market . that may be
about to change , thanks to chipmaking giant intel corp .

__label__2 bowled by the slower one again , kolkata , november 14 the past caught up with
sourav ganguly as the indian skippers return to international cricket was short lived .
```

##### Note

The order of labels within the sentence doesn't matter.

Upload the training file under the *train* channel, and optionally upload the validation file under the *validation* channel.

##### Train with Augmented Manifest Text Format

The supervised mode also supports the augmented manifest format, which enables you to do training in pipe mode without needing to create RecordIO files. While using the format, an S3 manifest file needs to be generated that contains the list of sentences and their corresponding labels. The manifest file format should be in [JSON Lines](#) format in which each line represents one sample. The sentences are specified using the `source` tag and the label can be specified using the `label` tag. Both `source` and `label` tags should be provided under the `AttributeNames` parameter value as specified in the request.

```
{"source":"linux ready for prime time , intel says , despite all the linux hype",
 "label":1}
{"source":"bowled by the slower one again , kolkata , november 14 the past caught up with
sourav ganguly", "label":2}
```

Multi-label training is also supported by specifying a JSON array of labels.

```
{"source":"linux ready for prime time , intel says , despite all the linux hype", "label":
 [1, 3]}
 {"source":"bowled by the slower one again , kolkata , november 14 the past caught up with
sourav ganguly", "label": [2, 4, 5]}
```

For more information on augmented manifest files, see [Provide Dataset Metadata to Training Jobs with an Augmented Manifest File \(p. 1864\)](#).

## Model Artifacts and Inference

### Model Artifacts for the Word2Vec Algorithm

For Word2Vec training, the model artifacts consist of `vectors.txt`, which contains words-to-vectors mapping, and `vectors.bin`, a binary used by BlazingText for hosting, inference, or both. `vectors.txt` stores the vectors in a format that is compatible with other tools like Gensim and Spacy. For example, a Gensim user can run the following commands to load the `vectors.txt` file:

```
from gensim.models import KeyedVectors
word_vectors = KeyedVectors.load_word2vec_format('vectors.txt', binary=False)
word_vectors.most_similar(positive=['woman', 'king'], negative=['man'])
word_vectors.doesnt_match("breakfast cereal dinner lunch".split())
```

If the evaluation parameter is set to `True`, an additional file, `eval.json`, is created. This file contains the similarity evaluation results (using Spearman's rank correlation coefficients) on WS-353 dataset. The number of words from the WS-353 dataset that aren't there in the training corpus are reported.

For inference requests, the model accepts a JSON file containing a list of strings and returns a list of vectors. If the word is not found in vocabulary, inference returns a vector of zeros. If subwords is set to `True` during training, the model is able to generate vectors for out-of-vocabulary (OOV) words.

### Sample JSON Request

Mime-type: `application/json`

```
{
  "instances": ["word1", "word2", "word3"]
}
```

### Model Artifacts for the Text Classification Algorithm

Training with supervised outputs creates a `model.bin` file that can be consumed by BlazingText hosting. For inference, the BlazingText model accepts a JSON file containing a list of sentences and returns a list of corresponding predicted labels and probability scores. Each sentence is expected to be a string with space-separated tokens, words, or both.

### Sample JSON Request

Mime-type: `application/json`

```
{
  "instances": ["the movie was excellent", "i did not like the plot ."]
}
```

By default, the server returns only one prediction, the one with the highest probability. For retrieving the top  $k$  predictions, you can set  $k$  in the configuration, as follows:

```
{
  "instances": ["the movie was excellent", "i did not like the plot ."],
  "configuration": {"k": 2}
}
```

For BlazingText, the `content-type` and `accept` parameters must be equal. For batch transform, they both need to be `application/jsonlines`. If they differ, the `Accept` field is ignored. The format for input follows:

```
content-type: application/jsonlines

{"source": "source_0"}
 {"source": "source_1"}

if you need to pass the value of k for top-k, then you can do it in the following way:

 {"source": "source_0", "k": 2}
 {"source": "source_1", "k": 3}
```

The format for output follows:

```
accept: application/jsonlines

 {"prob": [prob_1], "label": ["__label__1"]}
 {"prob": [prob_1], "label": ["__label__1"]}

If you have passed the value of k to be more than 1, then response will be in this format:

 {"prob": [prob_1, prob_2], "label": ["__label__1", "__label__2"]}
 {"prob": [prob_1, prob_2], "label": ["__label__1", "__label__2"]}
```

For both supervised (text classification) and unsupervised (Word2Vec) modes, the binaries (\*.bin) produced by BlazingText can be cross-consumed by fastText and vice versa. You can use binaries produced by BlazingText by fastText. Likewise, you can host the model binaries created with fastText using BlazingText.

Here is an example of how to use a model generated with BlazingText with fastText:

```
#Download the model artifact from S3
aws s3 cp s3://<YOUR_S3_BUCKET>/<PREFIX>/model.tar.gz model.tar.gz

#Unzip the model archive
tar -xzf model.tar.gz

#Use the model archive with fastText
fasttext predict ./model.bin test.txt
```

However, the binaries are only supported when training on CPU and single GPU; training on multi-GPU will not produce binaries.

For more details on dataset formats and model hosting, see the example notebooks [Text Classification with the BlazingText Algorithm](#), [FastText Models](#), and [Generating Subword Embeddings with the Word2Vec Algorithm](#).

## EC2 Instance Recommendation for the BlazingText Algorithm

For cbow and skipgram modes, BlazingText supports single CPU and single GPU instances. Both of these modes support learning of subwords embeddings. To achieve the highest speed without compromising accuracy, we recommend that you use an ml.p3.2xlarge instance.

For batch\_skipgram mode, BlazingText supports single or multiple CPU instances. When training on multiple instances, set the value of the `S3DataDistributionType` field of the `S3DataSource` object that you pass to `CreateTrainingJob` to `FullyReplicated`. BlazingText takes care of distributing data across machines.

For the supervised text classification mode, a C5 instance is recommended if the training dataset is less than 2 GB. For larger datasets, use an instance with a single GPU (ml.p2.xlarge or ml.p3.2xlarge).

## BlazingText Sample Notebooks

For a sample notebook that uses the SageMaker BlazingText algorithm to train and deploy supervised binary and multiclass classification models, see [Blazing Text classification on the DBpedia dataset](#). For instructions for creating and accessing Jupyter notebook instances that you can use to run the example in SageMaker, see [Use Amazon SageMaker Notebook Instances \(p. 120\)](#). After creating and opening a notebook instance, choose the **SageMaker Examples** tab to see a list of all the SageMaker examples. The topic modeling example notebooks that use the BlazingText are located in the **Introduction to Amazon algorithms** section. To open a notebook, choose its **Use** tab, then choose **Create copy**.

## BlazingText Hyperparameters

When you start a training job with a `CreateTrainingJob` request, you specify a training algorithm. You can also specify algorithm-specific hyperparameters as string-to-string maps. The hyperparameters for the BlazingText algorithm depend on which mode you use: Word2Vec (unsupervised) and Text Classification (supervised).

### Word2Vec Hyperparameters

The following table lists the hyperparameters for the BlazingText Word2Vec training algorithm provided by Amazon SageMaker.

Parameter Name	Description
<code>mode</code>	<p>The Word2vec architecture used for training.</p> <p><b>Required</b></p> <p>Valid values: <code>batch_skipgram</code>, <code>skipgram</code>, or <code>cbow</code></p>
<code>batch_size</code>	<p>The size of each batch when <code>mode</code> is set to <code>batch_skipgram</code>. Set to a number between 10 and 20.</p> <p><b>Optional</b></p> <p>Valid values: Positive integer</p> <p>Default value: 11</p>
<code>buckets</code>	<p>The number of hash buckets to use for subwords.</p> <p><b>Optional</b></p> <p>Valid values: positive integer</p> <p>Default value: 2000000</p>
<code>epochs</code>	<p>The number of complete passes through the training data.</p> <p><b>Optional</b></p> <p>Valid values: Positive integer</p> <p>Default value: 5</p>
<code>evaluation</code>	<p>Whether the trained model is evaluated using the <a href="#">WordSimilarity-353 Test</a>.</p> <p><b>Optional</b></p> <p>Valid values: (Boolean) <code>True</code> or <code>False</code></p>

Parameter Name	Description
	Default value: <code>True</code>
<code>learning_rate</code>	<p>The step size used for parameter updates.</p> <p><b>Optional</b></p> <p>Valid values: Positive float</p> <p>Default value: 0.05</p>
<code>min_char</code>	<p>The minimum number of characters to use for subwords/character n-grams.</p> <p><b>Optional</b></p> <p>Valid values: positive integer</p> <p>Default value: 3</p>
<code>min_count</code>	<p>Words that appear less than <code>min_count</code> times are discarded.</p> <p><b>Optional</b></p> <p>Valid values: Non-negative integer</p> <p>Default value: 5</p>
<code>max_char</code>	<p>The maximum number of characters to use for subwords/character n-grams</p> <p><b>Optional</b></p> <p>Valid values: positive integer</p> <p>Default value: 6</p>
<code>negative_samples</code>	<p>The number of negative samples for the negative sample sharing strategy.</p> <p><b>Optional</b></p> <p>Valid values: Positive integer</p> <p>Default value: 5</p>
<code>sampling_threshold</code>	<p>The threshold for the occurrence of words. Words that appear with higher frequency in the training data are randomly down-sampled.</p> <p><b>Optional</b></p> <p>Valid values: Positive fraction. The recommended range is (0, 1e-3]</p> <p>Default value: 0.0001</p>

Parameter Name	Description
<code>subwords</code>	<p>Whether to learn subword embeddings or not.</p> <p><b>Optional</b></p> <p>Valid values: (Boolean) <code>True</code> or <code>False</code></p> <p>Default value: <code>False</code></p>
<code>vector_dim</code>	<p>The dimension of the word vectors that the algorithm learns.</p> <p><b>Optional</b></p> <p>Valid values: Positive integer</p> <p>Default value: 100</p>
<code>window_size</code>	<p>The size of the context window. The context window is the number of words surrounding the target word used for training.</p> <p><b>Optional</b></p> <p>Valid values: Positive integer</p> <p>Default value: 5</p>

### Text Classification Hyperparameters

The following table lists the hyperparameters for the Text Classification training algorithm provided by Amazon SageMaker.

**Note**

Although some of the parameters are common between the Text Classification and Word2Vec modes, they might have different meanings depending on the context.

Parameter Name	Description
<code>mode</code>	<p>The training mode.</p> <p><b>Required</b></p> <p>Valid values: <code>supervised</code></p>
<code>buckets</code>	<p>The number of hash buckets to use for word n-grams.</p> <p><b>Optional</b></p> <p>Valid values: Positive integer</p> <p>Default value: 2000000</p>
<code>early_stopping</code>	<p>Whether to stop training if validation accuracy doesn't improve after a patience number of epochs.</p> <p><b>Optional</b></p> <p>Valid values: (Boolean) <code>True</code> or <code>False</code></p> <p>Default value: <code>False</code></p>

Parameter Name	Description
epochs	<p>The maximum number of complete passes through the training data.</p> <p><b>Optional</b></p> <p>Valid values: Positive integer</p> <p>Default value: 5</p>
learning_rate	<p>The step size used for parameter updates.</p> <p><b>Optional</b></p> <p>Valid values: Positive float</p> <p>Default value: 0.05</p>
min_count	<p>Words that appear less than <code>min_count</code> times are discarded.</p> <p><b>Optional</b></p> <p>Valid values: Non-negative integer</p> <p>Default value: 5</p>
min_epochs	<p>The minimum number of epochs to train before early stopping logic is invoked.</p> <p><b>Optional</b></p> <p>Valid values: Positive integer</p> <p>Default value: 5</p>
patience	<p>The number of epochs to wait before applying early stopping when no progress is made on the validation set. Used only when <code>early_stopping</code> is <code>True</code>.</p> <p><b>Optional</b></p> <p>Valid values: Positive integer</p> <p>Default value: 4</p>
vector_dim	<p>The dimension of the embedding layer.</p> <p><b>Optional</b></p> <p>Valid values: Positive integer</p> <p>Default value: 100</p>
word_ngrams	<p>The number of word n-gram features to use.</p> <p><b>Optional</b></p> <p>Valid values: Positive integer</p> <p>Default value: 2</p>

## Tune a BlazingText Model

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker \(p. 1745\)](#).

### Metrics Computed by the BlazingText Algorithm

The BlazingText Word2Vec algorithm (skipgram, cbow, and batch\_skipgram modes) reports on a single metric during training: `train:mean_rho`. This metric is computed on [WS-353 word similarity datasets](#). When tuning the hyperparameter values for the Word2Vec algorithm, use this metric as the objective.

The BlazingText Text Classification algorithm (supervised mode), also reports on a single metric during training: the `validation:accuracy`. When tuning the hyperparameter values for the text classification algorithm, use these metrics as the objective.

Metric Name	Description	Optimization Direction
<code>train:mean_rho</code>	The mean rho (Spearman's rank correlation coefficient) on <a href="#">WS-353 word similarity datasets</a>	Maximize
<code>validation:accuracy</code>	The classification accuracy on the user-specified validation dataset	Maximize

### Tunable BlazingText Hyperparameters

#### Tunable Hyperparameters for the Word2Vec Algorithm

Tune an Amazon SageMaker BlazingText Word2Vec model with the following hyperparameters. The hyperparameters that have the greatest impact on Word2Vec objective metrics are: `mode`, `learning_rate`, `window_size`, `vector_dim`, and `negative_samples`.

Parameter Name	Parameter Type	Recommended Ranges or Values
<code>batch_size</code>	<code>IntegerParameterRange</code>	[8-32]
<code>epochs</code>	<code>IntegerParameterRange</code>	[5-15]
<code>learning_rate</code>	<code>ContinuousParameterRange</code>	MinValue: 0.005, MaxValue: 0.01
<code>min_count</code>	<code>IntegerParameterRange</code>	[0-100]
<code>mode</code>	<code>CategoricalParameterRange</code>	['batch_skipgram', 'skipgram', 'cbow']
<code>negative_samples</code>	<code>IntegerParameterRange</code>	[5-25]
<code>sampling_threshold</code>	<code>ContinuousParameterRange</code>	MinValue: 0.0001, MaxValue: 0.001
<code>vector_dim</code>	<code>IntegerParameterRange</code>	[32-300]

Parameter Name	Parameter Type	Recommended Ranges or Values
window_size	IntegerParameterRange	[1-10]

### Tunable Hyperparameters for the Text Classification Algorithm

Tune an Amazon SageMaker BlazingText text classification model with the following hyperparameters.

Parameter Name	Parameter Type	Recommended Ranges or Values
buckets	IntegerParameterRange	[1000000-10000000]
epochs	IntegerParameterRange	[5-15]
learning_rate	ContinuousParameterRange	MinValue: 0.005, MaxValue: 0.01
min_count	IntegerParameterRange	[0-100]
mode	CategoricalParameterRange	['supervised']
vector_dim	IntegerParameterRange	[32-300]
word_ngrams	IntegerParameterRange	[1-3]

## DeepAR Forecasting Algorithm

The Amazon SageMaker DeepAR forecasting algorithm is a supervised learning algorithm for forecasting scalar (one-dimensional) time series using recurrent neural networks (RNN). Classical forecasting methods, such as autoregressive integrated moving average (ARIMA) or exponential smoothing (ETS), fit a single model to each individual time series. They then use that model to extrapolate the time series into the future.

In many applications, however, you have many similar time series across a set of cross-sectional units. For example, you might have time series groupings for demand for different products, server loads, and requests for webpages. For this type of application, you can benefit from training a single model jointly over all of the time series. DeepAR takes this approach. When your dataset contains hundreds of related time series, DeepAR outperforms the standard ARIMA and ETS methods. You can also use the trained model to generate forecasts for new time series that are similar to the ones it has been trained on.

The training input for the DeepAR algorithm is one or, preferably, more target time series that have been generated by the same process or similar processes. Based on this input dataset, the algorithm trains a model that learns an approximation of this process/processes and uses it to predict how the target time series evolves. Each target time series can be optionally associated with a vector of static (time-independent) categorical features provided by the `cat` field and a vector of dynamic (time-dependent) time series provided by the `dynamic_feat` field. SageMaker trains the DeepAR model by randomly sampling training examples from each target time series in the training dataset. Each training example consists of a pair of adjacent context and prediction windows with fixed predefined lengths. To control how far in the past the network can see, use the `context_length` hyperparameter. To control how far in the future predictions can be made, use the `prediction_length` hyperparameter. For more information, see [How the DeepAR Algorithm Works \(p. 1378\)](#).

## Input/Output Interface for the DeepAR Algorithm

DeepAR supports two data channels. The required `train` channel describes the training dataset. The optional `test` channel describes a dataset that the algorithm uses to evaluate model accuracy after training. You can provide training and test datasets in [JSON Lines](#) format. Files can be in gzip or [Parquet](#) file format.

When specifying the paths for the training and test data, you can specify a single file or a directory that contains multiple files, which can be stored in subdirectories. If you specify a directory, DeepAR uses all files in the directory as inputs for the corresponding channel, except those that start with a period (.) and those named `_SUCCESS`. This ensures that you can directly use output folders produced by Spark jobs as input channels for your DeepAR training jobs.

By default, the DeepAR model determines the input format from the file extension (`.json`, `.json.gz`, or `.parquet`) in the specified input path. If the path does not end in one of these extensions, you must explicitly specify the format in the SDK for Python. Use the `content_type` parameter of the [s3\\_input](#) class.

The records in your input files should contain the following fields:

- `start`—A string with the format `YYYY-MM-DD HH:MM:SS`. The start timestamp can't contain time zone information.
- `target`—An array of floating-point values or integers that represent the time series. You can encode missing values as `null` literals, or as "NaN" strings in JSON, or as `nan` floating-point values in Parquet.
- `dynamic_feat` (optional)—An array of arrays of floating-point values or integers that represents the vector of custom feature time series (dynamic features). If you set this field, all records must have the same number of inner arrays (the same number of feature time series). In addition, each inner array must be the same length as the associated `target` value plus length of the context. Missing values are not supported in the features. For example, if `target` time series represents the demand of different products, an associated `dynamic_feat` might be a boolean time-series which indicates whether a promotion was applied (1) to the particular product or not (0):

```
{"start": ..., "target": [1, 5, 10, 2], "dynamic_feat": [[0, 1, 1, 0]]}
```

- `cat` (optional)—An array of categorical features that can be used to encode the groups that the record belongs to. Categorical features must be encoded as a 0-based sequence of positive integers. For example, the categorical domain {R, G, B} can be encoded as {0, 1, 2}. All values from each categorical domain must be represented in the training dataset. That's because the DeepAR algorithm can forecast only for categories that have been observed during training. And, each categorical feature is embedded in a low-dimensional space whose dimensionality is controlled by the `embedding_dimension` hyperparameter. For more information, see [DeepAR Hyperparameters \(p. 1381\)](#).

If you use a JSON file, it must be in [JSON Lines](#) format. For example:

```
{"start": "2009-11-01 00:00:00", "target": [4.3, "NaN", 5.1, ...], "cat": [0, 1], "dynamic_feat": [[1.1, 1.2, 0.5, ...]]}
```

```
{"start": "2012-01-30 00:00:00", "target": [1.0, -5.0, ...], "cat": [2, 3], "dynamic_feat":  
[[1.1, 2.05, ...]]}  
{"start": "1999-01-30 00:00:00", "target": [2.0, 1.0], "cat": [1, 4], "dynamic_feat":  
[[1.3, 0.4]]}
```

In this example, each time series has two associated categorical features and one time series features.

For Parquet, you use the same three fields as columns. In addition, "start" can be the `datetime` type. You can compress Parquet files using gzip (`gzip`) or the Snappy compression library (`snappy`).

If the algorithm is trained without `cat` and `dynamic_feat` fields, it learns a "global" model, that is a model that is agnostic to the specific identity of the target time series at inference time and is conditioned only on its shape.

If the model is conditioned on the `cat` and `dynamic_feat` feature data provided for each time series, the prediction will probably be influenced by the character of time series with the corresponding `cat` features. For example, if the target time series represents the demand of clothing items, you can associate a two-dimensional `cat` vector that encodes the type of item (e.g. 0 = shoes, 1 = dress) in the first component and the color of an item (e.g. 0 = red, 1 = blue) in the second component. A sample input would look as follows:

```
{ "start": ..., "target": ..., "cat": [0, 0], ... } # red shoes  
{ "start": ..., "target": ..., "cat": [1, 1], ... } # blue dress
```

At inference time, you can request predictions for targets with `cat` values that are combinations of the `cat` values observed in the training data, for example:

```
{ "start": ..., "target": ..., "cat": [0, 1], ... } # blue shoes  
{ "start": ..., "target": ..., "cat": [1, 0], ... } # red dress
```

The following guidelines apply to training data:

- The start time and length of the time series can differ. For example, in marketing, products often enter a retail catalog at different dates, so their start dates naturally differ. But all series must have the same frequency, number of categorical features, and number of dynamic features.
- Shuffle the training file with respect to the position of the time series in the file. In other words, the time series should occur in random order in the file.
- Make sure to set the `start` field correctly. The algorithm uses the `start` timestamp to derive the internal features.
- If you use categorical features (`cat`), all time series must have the same number of categorical features. If the dataset contains the `cat` field, the algorithm uses it and extracts the cardinality of the groups from the dataset. By default, cardinality is "auto". If the dataset contains the `cat` field, but you don't want to use it, you can disable it by setting `cardinality` to "" . If a model was trained using a `cat` feature, you must include it for inference.
- If your dataset contains the `dynamic_feat` field, the algorithm uses it automatically. All time series have to have the same number of feature time series. The time points in each of the feature time series correspond one-to-one to the time points in the target. In addition, the entry in the `dynamic_feat` field should have the same length as the target. If the dataset contains the `dynamic_feat` field, but you don't want to use it, disable it by setting(`num_dynamic_feat` to "" ). If the model was trained with the `dynamic_feat` field, you must provide this field for inference. In addition, each of the features has to have the length of the provided target plus the `prediction_length`. In other words, you must provide the feature value in the future.

If you specify optional test channel data, the DeepAR algorithm evaluates the trained model with different accuracy metrics. The algorithm calculates the root mean square error (RMSE) over the test data as follows:

$$\text{RMSE} = \sqrt{\frac{1}{nT} \sum_{i,t} (\hat{y}_{i,t} - y_{i,t})^2}$$

$y_{i,t}$  is the true value of time series  $i$  at the time  $t$ .  $\hat{y}_{i,t}$  is the mean prediction. The sum is over all  $n$  time series in the test set and over the last  $T$  time points for each time series, where  $T$  corresponds to the forecast horizon. You specify the length of the forecast horizon by setting the [prediction\\_length](#) hyperparameter. For more information, see [DeepAR Hyperparameters \(p. 1381\)](#).

In addition, the algorithm evaluates the accuracy of the forecast distribution using weighted quantile loss. For a quantile in the range  $[0, 1]$ , the weighted quantile loss is defined as follows:

$$\text{wQuantileLoss}[\tau] = 2 \sum_{i,t} \frac{Q_{i,t}^{(\tau)}}{|y_{i,t}|}, \quad \text{with} \quad Q_{i,t}^{(\tau)} = \begin{cases} (1-\tau)|q_{i,t}^{(\tau)} - y_{i,t}| & \text{if } q_{i,t}^{(\tau)} > y_{i,t} \\ \tau|q_{i,t}^{(\tau)} - y_{i,t}| & \text{otherwise} \end{cases}$$

$q_{i,t}^{(\tau)}$  is the  $\tau$ -quantile of the distribution that the model predicts. To specify which quantiles to calculate loss for, set the [test\\_quantiles](#) hyperparameter. In addition to these, the average of the prescribed quantile losses is reported as part of the training logs. For information, see [DeepAR Hyperparameters \(p. 1381\)](#).

For inference, DeepAR accepts JSON format and the following fields:

- "instances", which includes one or more time series in JSON Lines format
- A name of "configuration", which includes parameters for generating the forecast

For more information, see [DeepAR Inference Formats \(p. 1386\)](#).

## Best Practices for Using the DeepAR Algorithm

When preparing your time series data, follow these best practices to achieve the best results:

- Except for when splitting your dataset for training and testing, always provide the entire time series for training, testing, and when calling the model for inference. Regardless of how you set `context_length`, don't break up the time series or provide only a part of it. The model uses data points further back than the value set in `context_length` for the lagged values feature.
- When tuning a DeepAR model, you can split the dataset to create a training dataset and a test dataset. In a typical evaluation, you would test the model on the same time series used for training, but on the future `prediction_length` time points that follow immediately after the last time point visible during training. You can create training and test datasets that satisfy this criteria by using the entire dataset (the full length of all time series that are available) as a test set and removing the last `prediction_length` points from each time series for training. During training, the model doesn't see the target values for time points on which it is evaluated during testing. During testing, the algorithm withholds the last `prediction_length` points of each time series in the test set and generates a prediction. Then it compares the forecast with the withheld values. You can create more complex evaluations by repeating time series multiple times in the test set, but cutting them at different endpoints. With this approach, accuracy metrics are averaged over multiple forecasts from different time points. For more information, see [Tune a DeepAR Model \(p. 1385\)](#).
- Avoid using very large values ( $>400$ ) for the `prediction_length` because it makes the model slow and less accurate. If you want to forecast further into the future, consider aggregating your data at a lower frequency. For example, use `5min` instead of `1min`.
- Because lags are used, a model can look further back in the time series than the value specified for `context_length`. Therefore, you don't need to set this parameter to a large value. We recommend starting with the value that you used for `prediction_length`.

- We recommend training a DeepAR model on as many time series as are available. Although a DeepAR model trained on a single time series might work well, standard forecasting algorithms, such as ARIMA or ETS, might provide more accurate results. The DeepAR algorithm starts to outperform the standard methods when your dataset contains hundreds of related time series. Currently, DeepAR requires that the total number of observations available across all training time series is at least 300.

## EC2 Instance Recommendations for the DeepAR Algorithm

You can train DeepAR on both GPU and CPU instances and in both single and multi-machine settings. We recommend starting with a single CPU instance (for example, ml.c4.2xlarge or ml.c4.4xlarge), and switching to GPU instances and multiple machines only when necessary. Using GPUs and multiple machines improves throughput only for larger models (with many cells per layer and many layers) and for large mini-batch sizes (for example, greater than 512).

For inference, DeepAR supports only CPU instances.

Specifying large values for `context_length`, `prediction_length`, `num_cells`, `num_layers`, or `mini_batch_size` can create models that are too large for small instances. In this case, use a larger instance type or reduce the values for these parameters. This problem also frequently occurs when running hyperparameter tuning jobs. In that case, use an instance type large enough for the model tuning job and consider limiting the upper values of the critical parameters to avoid job failures.

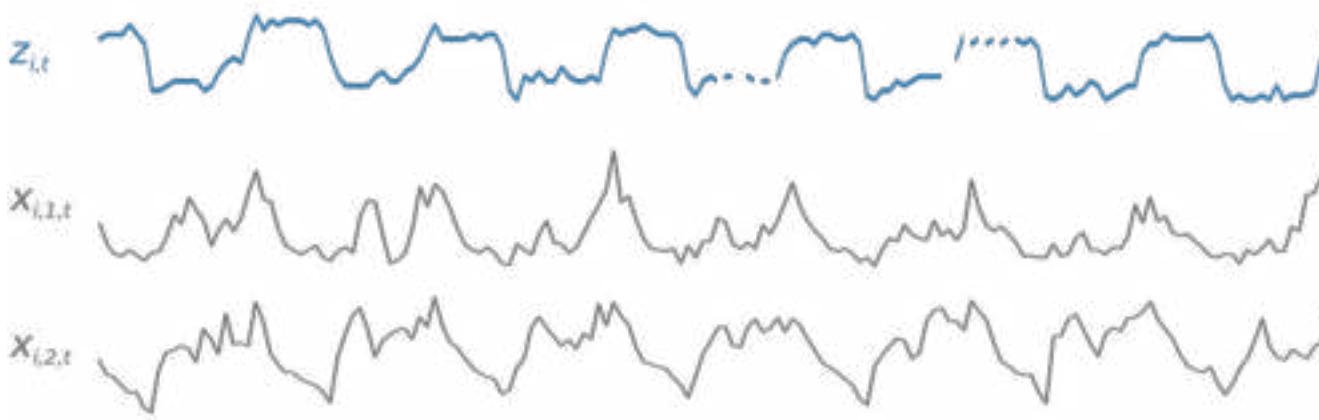

## DeepAR Sample Notebooks

For a sample notebook that shows how to prepare a time series dataset for training the SageMaker DeepAR algorithm and how to deploy the trained model for performing inferences, see [Time series forecasting with DeepAR - Synthetic data](#) as well as [DeepAR demo on electricity dataset](#), which illustrates the advanced features of DeepAR on a real world dataset. For instructions on creating and accessing Jupyter notebook instances that you can use to run the example in SageMaker, see [Use Amazon SageMaker Notebook Instances \(p. 120\)](#). After creating and opening a notebook instance, choose the **SageMaker Examples** tab to see a list of all of the SageMaker examples. To open a notebook, choose its **Use** tab, and choose **Create copy**.

## How the DeepAR Algorithm Works

During training, DeepAR accepts a training dataset and an optional test dataset. It uses the test dataset to evaluate the trained model. In general, the datasets don't have to contain the same set of time series. You can use a model trained on a given training set to generate forecasts for the future of the time series in the training set, and for other time series. Both the training and the test datasets consist of one or, preferably, more target time series. Each target time series can optionally be associated with a vector of feature time series and a vector of categorical features. For more information, see [Input/Output Interface for the DeepAR Algorithm \(p. 1375\)](#).

For example, the following is an element of a training set indexed by  $i$  which consists of a target time series,  $Z_{i,t}$ , and two associated feature time series,  $X_{i,1,t}$  and  $X_{i,2,t}$ :

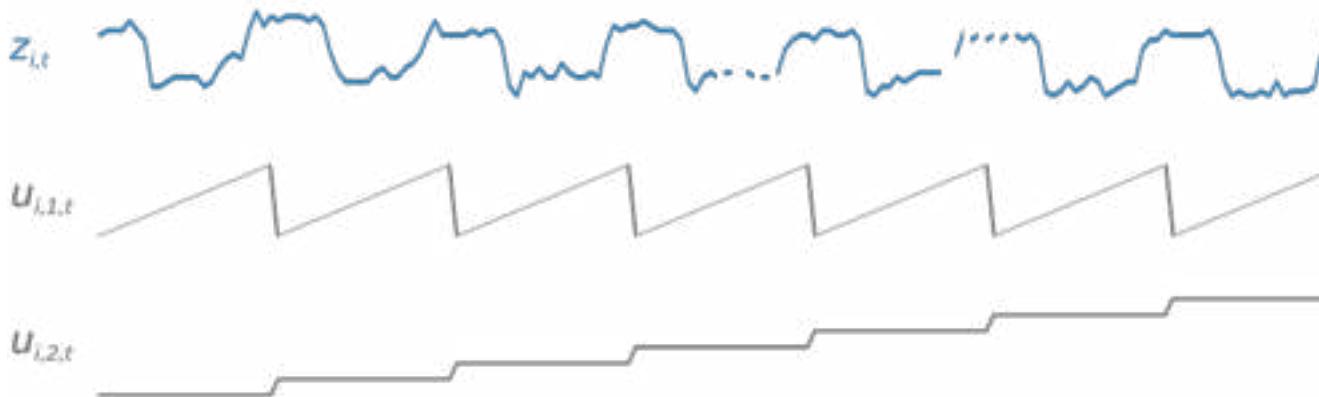

The target time series might contain missing values, which are represented by line breaks in the time series. DeepAR supports only feature time series that are known in the future. This allows you to run "what if?" scenarios. What happens, for example, if I change the price of a product in some way?

Each target time series can also be associated with a number of categorical features. You can use these features to encode which groupings a time series belongs to. Categorical features allow the model to learn typical behavior for groups, which it can use to increase model accuracy. DeepAR implements this by learning an embedding vector for each group that captures the common properties of all time series in the group.

#### How Feature Time Series Work in the DeepAR Algorithm

To facilitate learning time-dependent patterns, such as spikes during weekends, DeepAR automatically creates feature time series based on the frequency of the target time series. For example, DeepAR creates two feature time series (day of the month and day of the year) for a weekly time series frequency. It uses these derived feature time series with the custom feature time series that you provide during training and inference. The following figure shows two of these derived time series features:  $u_{i,1,t}$  represents the hour of the day and  $u_{i,2,t}$  the day of the week.

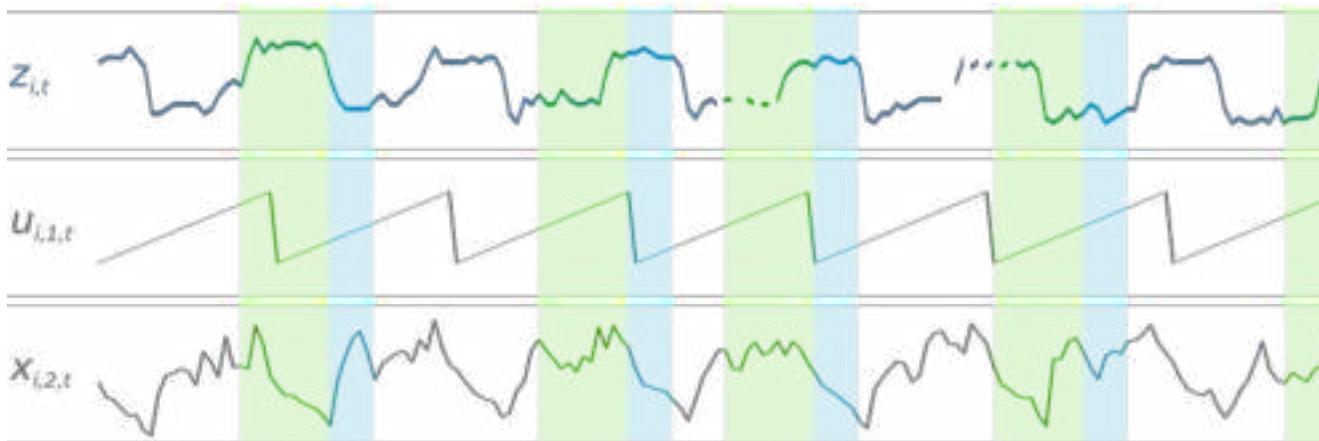

The DeepAR algorithm automatically generates these feature time series. The following table lists the derived features for the supported basic time frequencies.

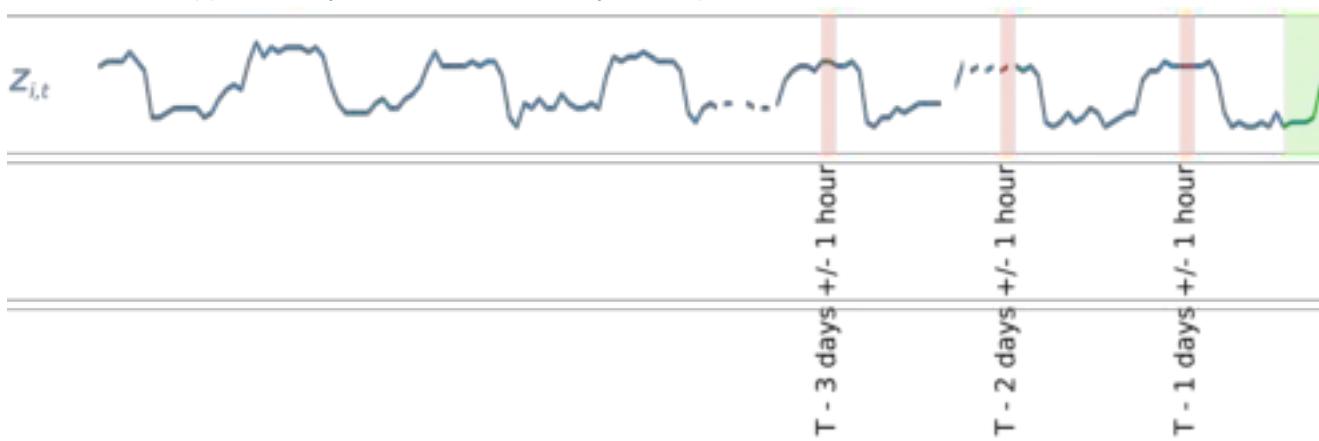

Frequency of the Time Series	Derived Features
Minute	minute-of-hour, hour-of-day, day-of-week, day-of-month, day-of-year

Frequency of the Time Series	Derived Features
Hour	hour-of-day, day-of-week, day-of-month, day-of-year
Day	day-of-week, day-of-month, day-of-year
Week	day-of-month, week-of-year
Month	month-of-year

DeepAR trains a model by randomly sampling several training examples from each of the time series in the training dataset. Each training example consists of a pair of adjacent context and prediction windows with fixed predefined lengths. The `context_length` hyperparameter controls how far in the past the network can see, and the `prediction_length` hyperparameter controls how far in the future predictions can be made. During training, the algorithm ignores training set elements containing time series that are shorter than a specified prediction length. The following figure represents five samples with context lengths of 12 hours and prediction lengths of 6 hours drawn from element  $i$ . For brevity, we've omitted the feature time series  $x_{i,1,t}$  and  $u_{i,2,t}$ .

To capture seasonality patterns, DeepAR also automatically feeds lagged values from the target time series. In the example with hourly frequency, for each time index,  $t = T$ , the model exposes the  $z_{i,t}$  values, which occurred approximately one, two, and three days in the past.

For inference, the trained model takes as input target time series, which might or might not have been used during training, and forecasts a probability distribution for the next `prediction_length` values.

Because DeepAR is trained on the entire dataset, the forecast takes into account patterns learned from similar time series.

For information on the mathematics behind DeepAR, see [DeepAR: Probabilistic Forecasting with Autoregressive Recurrent Networks](#).

## DeepAR Hyperparameters

Parameter Name	Description
context_length	<p>The number of time-points that the model gets to see before making the prediction. The value for this parameter should be about the same as the <code>prediction_length</code>. The model also receives lagged inputs from the target, so <code>context_length</code> can be much smaller than typical seasonalities. For example, a daily time series can have yearly seasonality. The model automatically includes a lag of one year, so the context length can be shorter than a year. The lag values that the model picks depend on the frequency of the time series. For example, lag values for daily frequency are previous week, 2 weeks, 3 weeks, 4 weeks, and year.</p> <p><b>Required</b></p> <p>Valid values: Positive integer</p>
epochs	<p>The maximum number of passes over the training data. The optimal value depends on your data size and learning rate. See also <code>early_stopping_patience</code>. Typical values range from 10 to 1000.</p> <p><b>Required</b></p> <p>Valid values: Positive integer</p>
prediction_length	<p>The number of time-steps that the model is trained to predict, also called the forecast horizon. The trained model always generates forecasts with this length. It can't generate longer forecasts. The <code>prediction_length</code> is fixed when a model is trained and it cannot be changed later.</p> <p><b>Required</b></p> <p>Valid values: Positive integer</p>
time_freq	<p>The granularity of the time series in the dataset. Use <code>time_freq</code> to select appropriate date features and lags. The model supports the following basic frequencies. It also supports multiples of these basic frequencies. For example, <code>5min</code> specifies a frequency of 5 minutes.</p> <ul style="list-style-type: none"> <li>• <code>M</code>: monthly</li> <li>• <code>W</code>: weekly</li> <li>• <code>D</code>: daily</li> <li>• <code>H</code>: hourly</li> <li>• <code>min</code>: every minute</li> </ul> <p><b>Required</b></p>

Parameter Name	Description
	<p>Valid values: An integer followed by <i>M</i>, <i>W</i>, <i>D</i>, <i>H</i>, or <i>min</i>. For example, 5min.</p>
<code>cardinality</code>	<p>When using the categorical features (<code>cat</code>), <code>cardinality</code> is an array specifying the number of categories (groups) per categorical feature. Set this to <code>auto</code> to infer the cardinality from the data. The <code>auto</code> mode also works when no categorical features are used in the dataset. This is the recommended setting for the parameter.</p> <p>Set <code>cardinality</code> to <code>ignore</code> to force DeepAR to not use categorical features, even if they are present in the data.</p> <p>To perform additional data validation, it is possible to explicitly set this parameter to the actual value. For example, if two categorical features are provided where the first has 2 and the other has 3 possible values, set this to [2, 3].</p> <p>For more information on how to use categorical feature, see the data-section on the main documentation page of DeepAR.</p> <p><b>Optional</b></p> <p>Valid values: <code>auto</code>, <code>ignore</code>, array of positive integers, empty string, or</p> <p>Default value: <code>auto</code></p>
<code>dropout_rate</code>	<p>The dropout rate to use during training. The model uses zoneout regularization. For each iteration, a random subset of hidden neurons are not updated. Typical values are less than 0.2.</p> <p><b>Optional</b></p> <p>Valid values: float</p> <p>Default value: 0.1</p>
<code>early_stopping_patience</code>	<p>If this parameter is set, training stops when no progress is made within the specified number of epochs. The model that has the lowest loss is returned as the final model.</p> <p><b>Optional</b></p> <p>Valid values: integer</p>

Parameter Name	Description
embedding_dimension	<p>Size of embedding vector learned per categorical feature (same value is used for all categorical features).</p> <p>The DeepAR model can learn group-level time series patterns when a categorical grouping feature is provided. To do this, the model learns an embedding vector of size <code>embedding_dimension</code> for each group, capturing the common properties of all time series in the group. A larger <code>embedding_dimension</code> allows the model to capture more complex patterns. However, because increasing the <code>embedding_dimension</code> increases the number of parameters in the model, more training data is required to accurately learn these parameters. Typical values for this parameter are between 10-100.</p> <p><b>Optional</b></p> <p>Valid values: positive integer</p> <p>Default value: 10</p>
learning_rate	<p>The learning rate used in training. Typical values range from 1e-4 to 1e-1.</p> <p><b>Optional</b></p> <p>Valid values: float</p> <p>Default value: 1e-3</p>
likelihood	<p>The model generates a probabilistic forecast, and can provide quantiles of the distribution and return samples. Depending on your data, select an appropriate likelihood (noise model) that is used for uncertainty estimates. The following likelihoods can be selected:</p> <ul style="list-style-type: none"> <li>• <i>gaussian</i>: Use for real-valued data.</li> <li>• <i>beta</i>: Use for real-valued targets between 0 and 1 inclusive.</li> <li>• <i>negative-binomial</i>: Use for count data (non-negative integers).</li> <li>• <i>student-T</i>: An alternative for real-valued data that works well for bursty data.</li> <li>• <i>deterministic-L1</i>: A loss function that does not estimate uncertainty and only learns a point forecast.</li> </ul> <p><b>Optional</b></p> <p>Valid values: One of <i>gaussian</i>, <i>beta</i>, <i>negative-binomial</i>, <i>student-T</i>, or <i>deterministic-L1</i>.</p> <p>Default value: <code>student-T</code></p>

Parameter Name	Description
mini_batch_size	<p>The size of mini-batches used during training. Typical values range from 32 to 512.</p> <p><b>Optional</b></p> <p>Valid values: positive integer</p> <p>Default value: 128</p>
num_cells	<p>The number of cells to use in each hidden layer of the RNN. Typical values range from 30 to 100.</p> <p><b>Optional</b></p> <p>Valid values: positive integer</p> <p>Default value: 40</p>
num_dynamic_feat	<p>The number of <code>dynamic_feat</code> provided in the data. Set this to <code>auto</code> to infer the number of dynamic features from the data. The <code>auto</code> mode also works when no dynamic features are used in the dataset. This is the recommended setting for the parameter.</p> <p>To force DeepAR to not use dynamic features, even if they are present in the data, set <code>num_dynamic_feat</code> to <code>ignore</code>.</p> <p>To perform additional data validation, it is possible to explicitly set this parameter to the actual integer value. For example, if two dynamic features are provided, set this to 2.</p> <p><b>Optional</b></p> <p>Valid values: <code>auto</code>, <code>ignore</code>, positive integer, or empty string</p> <p>Default value: <code>auto</code></p>
num_eval_samples	<p>The number of samples that are used per time-series when calculating test accuracy metrics. This parameter does not have any influence on the training or the final model. In particular, the model can be queried with a different number of samples. This parameter only affects the reported accuracy scores on the test channel after training. Smaller values result in faster evaluation, but then the evaluation scores are typically worse and more uncertain. When evaluating with higher quantiles, for example 0.95, it may be important to increase the number of evaluation samples.</p> <p><b>Optional</b></p> <p>Valid values: integer</p> <p>Default value: 100</p>

Parameter Name	Description
<code>num_layers</code>	<p>The number of hidden layers in the RNN. Typical values range from 1 to 4.</p> <p><b>Optional</b></p> <p>Valid values: positive integer</p> <p>Default value: 2</p>
<code>test_quantiles</code>	<p>Quantiles for which to calculate quantile loss on the test channel.</p> <p><b>Optional</b></p> <p>Valid values: array of floats</p> <p>Default value: [0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9]</p>

## Tune a DeepAR Model

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker \(p. 1745\)](#).

### Metrics Computed by the DeepAR Algorithm

The DeepAR algorithm reports three metrics, which are computed during training. When tuning a model, choose one of these as the objective. For the objective, use either the forecast accuracy on a provided test channel (recommended) or the training loss. For recommendations for the training/test split for the DeepAR algorithm, see [Best Practices for Using the DeepAR Algorithm \(p. 1377\)](#).

Metric Name	Description	Optimization Direction
<code>test:RMSE</code>	The root mean square error between the forecast and the actual target computed on the test set.	Minimize
<code>test:mean_wQuantileLoss</code>	The average overall quantile losses computed on the test set. To control which quantiles are used, set the <code>test_quantiles</code> hyperparameter.	Minimize
<code>train:final_loss</code>	The training negative log-likelihood loss averaged over the last training epoch for the model.	Minimize

### Tunable Hyperparameters for the DeepAR Algorithm

Tune a DeepAR model with the following hyperparameters. The hyperparameters that have the greatest impact, listed in order from the most to least impactful, on DeepAR objective metrics are: `epochs`, `context_length`, `mini_batch_size`, `learning_rate`, and `num_cells`.

Parameter Name	Parameter Type	Recommended Ranges
mini_batch_size	IntegerParameterRanges	MinValue: 32, MaxValue: 1028
epochs	IntegerParameterRanges	MinValue: 1, MaxValue: 1000
context_length	IntegerParameterRanges	MinValue: 1, MaxValue: 200
num_cells	IntegerParameterRanges	MinValue: 30, MaxValue: 200
num_layers	IntegerParameterRanges	MinValue: 1, MaxValue: 8
dropout_rate	ContinuousParameterRange	MinValue: 0.00, MaxValue: 0.2
embedding_dimension	IntegerParameterRanges	MinValue: 1, MaxValue: 50
learning_rate	ContinuousParameterRange	MinValue: 1e-5, MaxValue: 1e-1

## DeepAR Inference Formats

### DeepAR JSON Request Formats

Query a trained model by using the model's endpoint. The endpoint takes the following JSON request format.

In the request, the `instances` field corresponds to the time series that should be forecast by the model.

If the model was trained with categories, you must provide a `cat` for each instance. If the model was trained without the `cat` field, it should be omitted.

If the model was trained with a custom feature time series (`dynamic_feat`), you have to provide the same number of `dynamic_feat` values for each instance. Each of them should have a length given by `length(target) + prediction_length`, where the last `prediction_length` values correspond to the time points in the future that will be predicted. If the model was trained without custom feature time series, the field should not be included in the request.

```
{
  "instances": [
    {
      "start": "2009-11-01 00:00:00",
      "target": [4.0, 10.0, "NaN", 100.0, 113.0],
      "cat": [0, 1],
      "dynamic_feat": [[1.0, 1.1, 2.1, 0.5, 3.1, 4.1, 1.2, 5.0, ...]]
    },
    {
      "start": "2012-01-30",
      "target": [1.0],
      "cat": [2, 1],
      "dynamic_feat": [[2.0, 3.1, 4.5, 1.5, 1.8, 3.2, 0.1, 3.0, ...]]
    },
    {
      "start": "1999-01-30",
      ...
    }
  ]
}
```

```

        "target": [2.0, 1.0],
        "cat": [1, 3],
        "dynamic_feat": [[1.0, 0.1, -2.5, 0.3, 2.0, -1.2, -0.1, -3.0, ...]]
    }
],
"configuration": {
    "num_samples": 50,
    "output_types": ["mean", "quantiles", "samples"],
    "quantiles": ["0.5", "0.9"]
}
}

```

The `configuration` field is optional. `configuration.num_samples` sets the number of sample paths that the model generates to estimate the mean and quantiles. `configuration.output_types` describes the information that will be returned in the request. Valid values are `"mean"`, `"quantiles"` and `"samples"`. If you specify `"quantiles"`, each of the quantile values in `configuration.quantiles` is returned as a time series. If you specify `"samples"`, the model also returns the raw samples used to calculate the other outputs.

### DeepAR JSON Response Formats

The following is the format of a response, where `[ ... ]` are arrays of numbers:

```
{
  "predictions": [
    {
      "quantiles": {
        "0.9": [...],
        "0.5": [...]
      },
      "samples": [...],
      "mean": [...]
    },
    {
      "quantiles": {
        "0.9": [...],
        "0.5": [...]
      },
      "samples": [...],
      "mean": [...]
    },
    {
      "quantiles": {
        "0.9": [...],
        "0.5": [...]
      },
      "samples": [...],
      "mean": [...]
    }
  ]
}
```

DeepAR has a response timeout of 60 seconds. When passing multiple time series in a single request, the forecasts are generated sequentially. Because the forecast for each time series typically takes about 300 to 1000 milliseconds or longer, depending on the model size, passing too many time series in a single request can cause time outs. It's better to send fewer time series per request and send more requests. Because the DeepAR algorithm uses multiple workers per instance, you can achieve much higher throughput by sending multiple requests in parallel.

By default, DeepAR uses one worker per CPU for inference, if there is sufficient memory per CPU. If the model is large and there isn't enough memory to run a model on each CPU, the number of workers is reduced. The number of workers used for inference can be overwritten using the environment variable

`MODEL_SERVER_WORKERS` For example, by setting `MODEL_SERVER_WORKERS=1`) when calling the SageMaker [CreateModel](#) API.

### Batch Transform with the DeepAR Algorithm

DeepAR forecasting supports getting inferences by using batch transform from data using the JSON Lines format. In this format, each record is represented on a single line as a JSON object, and lines are separated by newline characters. The format is identical to the JSON Lines format used for model training. For information, see [Input/Output Interface for the DeepAR Algorithm \(p. 1375\)](#). For example:

```
{"start": "2009-11-01 00:00:00", "target": [4.3, "NaN", 5.1, ...], "cat": [0, 1],  
"dynamic_feat": [[1.1, 1.2, 0.5, ...]]}  
{ "start": "2012-01-30 00:00:00", "target": [1.0, -5.0, ...], "cat": [2, 3], "dynamic_feat":  
[[1.1, 2.05, ...]]}  
{ "start": "1999-01-30 00:00:00", "target": [2.0, 1.0], "cat": [1, 4], "dynamic_feat":  
[[1.3, 0.4]]}
```

#### Note

When creating the transformation job with [CreateTransformJob](#), set the `BatchStrategy` value to `SingleRecord` and set the `SplitType` value in the `TransformInput` configuration to `Line`, as the default values currently cause runtime failures.

Similar to the hosted endpoint inference request format, the `cat` and the `dynamic_feat` fields for each instance are required if both of the following are true:

- The model is trained on a dataset that contained both the `cat` and the `dynamic_feat` fields.
- The corresponding `cardinality` and `num_dynamic_feat` values used in the training job are not set to `" "`.

Unlike hosted endpoint inference, the configuration field is set once for the entire batch inference job using an environment variable named `DEEPAR_INFERENCE_CONFIG`. The value of `DEEPAR_INFERENCE_CONFIG` can be passed when the model is created by calling [CreateTransformJob](#) API. If `DEEPAR_INFERENCE_CONFIG` is missing in the container environment, the inference container uses the following default:

```
{  
    "num_samples": 100,  
    "output_types": ["mean", "quantiles"],  
    "quantiles": ["0.1", "0.2", "0.3", "0.4", "0.5", "0.6", "0.7", "0.8", "0.9"]  
}
```

The output is also in JSON Lines format, with one line per prediction, in an order identical to the instance order in the corresponding input file. Predictions are encoded as objects identical to the ones returned by responses in online inference mode. For example:

```
{ "quantiles": { "0.1": [...], "0.2": [...] }, "samples": [...], "mean": [...] }
```

Note that in the `TransformInput` configuration of the SageMaker [CreateTransformJob](#) request clients must explicitly set the `AssembleWith` value to `Line`, as the default value `None` concatenates all JSON objects on the same line.

For example, here is a SageMaker [CreateTransformJob](#) request for a DeepAR job with a custom `DEEPAR_INFERENCE_CONFIG`:

```
{  
    "BatchStrategy": "SingleRecord",  
    "Environment": {  
        "DEEPAR_INFERENCE_CONFIG" : "{ \"num_samples\": 200, \"output_types\": [\"mean\"] }",  
    },  
    "ModelArn": "arn:aws:sagemaker:us-west-2:123456789012:transformer:my-deepar-transformer",  
    "TransformInput": {  
        "FileContentLocation": "s3://my-bucket/input-data",  
        "AssembleWith": "Line",  
        "ContentType": "text/plain",  
        "SplitType": "Line",  
        "SourceType": "File",  
        "CompressionType": "None"  
    },  
    "TransformOutput": {  
        "FileContentLocation": "s3://my-bucket/output-data",  
        "AssembleWith": "Line",  
        "ContentType": "text/plain",  
        "SplitType": "Line",  
        "SourceType": "File",  
        "CompressionType": "None"  
    },  
    "TransformResources": {  
        "ClusterConfig": {  
            "InstanceType": "ml.m5.xlarge",  
            "InstanceCount": 1  
        }  
    },  
    "TransformTimeout": 3600  
}
```

```
    ...
},
"TransformInput": {
    "SplitType": "Line",
    ...
},
"TransformOutput": {
    "AssembleWith": "Line",
    ...
},
...
}
```

## Factorization Machines Algorithm

The Factorization Machines algorithm is a general-purpose supervised learning algorithm that you can use for both classification and regression tasks. It is an extension of a linear model that is designed to capture interactions between features within high dimensional sparse datasets economically. For example, in a click prediction system, the Factorization Machines model can capture click rate patterns observed when ads from a certain ad-category are placed on pages from a certain page-category. Factorization machines are a good choice for tasks dealing with high dimensional sparse datasets, such as click prediction and item recommendation.

### Note

The Amazon SageMaker implementation of the Factorization Machines algorithm considers only pair-wise (2nd order) interactions between features.

## Input/Output Interface for the Factorization Machines Algorithm

The Factorization Machines algorithm can be run in either in binary classification mode or regression mode. In each mode, a dataset can be provided to the **test** channel along with the train channel dataset. The scoring depends on the mode used. In regression mode, the testing dataset is scored using Root Mean Square Error (RMSE). In binary classification mode, the test dataset is scored using Binary Cross Entropy (Log Loss), Accuracy (at threshold=0.5) and F1 Score (at threshold =0.5).

For **training**, the Factorization Machines algorithm currently supports only the `recordIO-protobuf` format with `Float32` tensors. Because their use case is predominantly on sparse data, CSV is not a good candidate. Both File and Pipe mode training are supported for recordIO-wrapped protobuf.

For **inference**, the Factorization Machines algorithm supports the `application/json` and `x-recordio-protobuf` formats.

- For the **binary classification** problem, the algorithm predicts a score and a label. The label is a number and can be either 0 or 1. The score is a number that indicates how strongly the algorithm believes that the label should be 1. The algorithm computes score first and then derives the label from the score value. If the score is greater than or equal to 0.5, the label is 1.
- For the **regression** problem, just a score is returned and it is the predicted value. For example, if Factorization Machines is used to predict a movie rating, score is the predicted rating value.

Please see [Factorization Machines Sample Notebooks \(p. 1390\)](#) for more details on training and inference file formats.

## EC2 Instance Recommendation for the Factorization Machines Algorithm

The Amazon SageMaker Factorization Machines algorithm is highly scalable and can train across distributed instances. We recommend training and inference with CPU instances for both sparse and dense datasets. In some circumstances, training with one or more GPUs on dense data might provide some benefit. Training with GPUs is available only on dense data. Use CPU instances for sparse data.

## Factorization Machines Sample Notebooks

For a sample notebook that uses the SageMaker Factorization Machines algorithm to analyze the images of handwritten digits from zero to nine in the MNIST dataset, see [An Introduction to Factorization Machines with MNIST](#). For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see [Use Amazon SageMaker Notebook Instances \(p. 120\)](#). Once you have created a notebook instance and opened it, select the **SageMaker Examples** tab to see a list of all the SageMaker samples. Example notebooks that use Factorization Machines algorithm are located in the **Introduction to Amazon algorithms** section. To open a notebook, click on its **Use** tab and select **Create copy**.

## How Factorization Machines Work

The prediction task for a Factorization Machines model is to estimate a function  $\hat{y}$  from a feature set  $x_i$  to a target domain. This domain is real-valued for regression and binary for classification. The Factorization Machines model is supervised and so has a training dataset  $(x_i, y_j)$  available. The advantages this model presents lie in the way it uses a factorized parametrization to capture the pairwise feature interactions. It can be represented mathematically as follows:

$$\hat{y} = w_0 + \sum_i w_i x_i + \sum_i \sum_{j > i} \langle v_i, v_j \rangle x_i x_j$$

The three terms in this equation correspond respectively to the three components of the model:

- The  $w_0$  term represents the global bias.
- The  $w_i$  linear terms model the strength of the  $i^{\text{th}}$  variable.
- The  $\langle v_i, v_j \rangle$  factorization terms model the pairwise interaction between the  $i^{\text{th}}$  and  $j^{\text{th}}$  variable.

The global bias and linear terms are the same as in a linear model. The pairwise feature interactions are modeled in the third term as the inner product of the corresponding factors learned for each feature. Learned factors can also be considered as embedding vectors for each feature. For example, in a classification task, if a pair of features tends to co-occur more often in positive labeled samples, then the inner product of their factors would be large. In other words, their embedding vectors would be close to each other in cosine similarity. For more information about the Factorization Machines model, see [Factorization Machines](#).

For regression tasks, the model is trained by minimizing the squared error between the model prediction  $\hat{y}_n$  and the target value  $y_n$ . This is known as the square loss:

$$L = \frac{1}{N} \sum_n (y_n - \hat{y}_n)^2$$

For a classification task, the model is trained by minimizing the cross entropy loss, also known as the log loss:

$$L = \frac{1}{N} \sum_n [y_n \log \hat{p}_n + (1 - y_n) \log (1 - \hat{p}_n)]$$

where:

$$\hat{p}_n = \frac{1}{1 + e^{-\hat{y}_n}}$$

For more information about loss functions for classification, see [Loss functions for classification](#).

## Factorization Machines Hyperparameters

The following table contains the hyperparameters for the Factorization Machines algorithm. These are parameters that are set by users to facilitate the estimation of model parameters from data. The required hyperparameters that must be set are listed first, in alphabetical order. The optional hyperparameters that can be set are listed next, also in alphabetical order.

Parameter Name	Description
<code>feature_dim</code>	<p>The dimension of the input feature space. This could be very high with sparse input.</p> <p><b>Required</b></p> <p>Valid values: Positive integer. Suggested value range: [10000,10000000]</p>
<code>num_factors</code>	<p>The dimensionality of factorization.</p> <p><b>Required</b></p> <p>Valid values: Positive integer. Suggested value range: [2,1000], 64 typically generates good outcomes and is a good starting point.</p>
<code>predictor_type</code>	<p>The type of predictor.</p> <ul style="list-style-type: none"> <li>• <code>binary_classifier</code>: For binary classification tasks.</li> <li>• <code>regressor</code>: For regression tasks.</li> </ul> <p><b>Required</b></p> <p>Valid values: String: <code>binary_classifier</code> or <code>regressor</code></p>
<code>bias_init_method</code>	<p>The initialization method for the bias term:</p> <ul style="list-style-type: none"> <li>• <code>normal</code>: Initializes weights with random values sampled from a normal distribution with a mean of zero and standard deviation specified by <code>bias_init_sigma</code>.</li> <li>• <code>uniform</code>: Initializes weights with random values uniformly sampled from a range specified by <code>-bias_init_scale</code>, <code>+bias_init_scale</code>.</li> <li>• <code>constant</code>: Initializes the weights to a scalar value specified by <code>bias_init_value</code>.</li> </ul> <p><b>Optional</b></p> <p>Valid values: <code>uniform</code>, <code>normal</code>, or <code>constant</code></p> <p>Default value: <code>normal</code></p>

Parameter Name	Description
bias_init_scale	<p>Range for initialization of the bias term. Takes effect if <code>bias_init_method</code> is set to <code>uniform</code>.</p> <p><b>Optional</b></p> <p>Valid values: Non-negative float. Suggested value range: [1e-8, 512].</p> <p>Default value: None</p>
bias_init_sigma	<p>The standard deviation for initialization of the bias term. Takes effect if <code>bias_init_method</code> is set to <code>normal</code>.</p> <p><b>Optional</b></p> <p>Valid values: Non-negative float. Suggested value range: [1e-8, 512].</p> <p>Default value: 0.01</p>
bias_init_value	<p>The initial value of the bias term. Takes effect if <code>bias_init_method</code> is set to <code>constant</code>.</p> <p><b>Optional</b></p> <p>Valid values: Float. Suggested value range: [1e-8, 512].</p> <p>Default value: None</p>
bias_lr	<p>The learning rate for the bias term.</p> <p><b>Optional</b></p> <p>Valid values: Non-negative float. Suggested value range: [1e-8, 512].</p> <p>Default value: 0.1</p>
bias_wd	<p>The weight decay for the bias term.</p> <p><b>Optional</b></p> <p>Valid values: Non-negative float. Suggested value range: [1e-8, 512].</p> <p>Default value: 0.01</p>
clip_gradient	<p>Gradient clipping optimizer parameter. Clips the gradient by projecting onto the interval [-<code>clip_gradient</code>, +<code>clip_gradient</code>].</p> <p><b>Optional</b></p> <p>Valid values: Float</p> <p>Default value: None</p>

Parameter Name	Description
epochs	<p>The number of training epochs to run.</p> <p><b>Optional</b></p> <p>Valid values: Positive integer</p> <p>Default value: 1</p>
eps	<p>Epsilon parameter to avoid division by 0.</p> <p><b>Optional</b></p> <p>Valid values: Float. Suggested value: small.</p> <p>Default value: None</p>
factors_init_method	<p>The initialization method for factorization terms:</p> <ul style="list-style-type: none"> <li>• <code>normal</code>: Initializes weights with random values sampled from a normal distribution with a mean of zero and standard deviation specified by <code>factors_init_sigma</code>.</li> <li>• <code>uniform</code>: Initializes weights with random values uniformly sampled from a range specified by <code>[-factors_init_scale, +factors_init_scale]</code>.</li> <li>• <code>constant</code>: Initializes the weights to a scalar value specified by <code>factors_init_value</code>.</li> </ul> <p><b>Optional</b></p> <p>Valid values: <code>uniform</code>, <code>normal</code>, or <code>constant</code>.</p> <p>Default value: <code>normal</code></p>
factors_init_scale	<p>The range for initialization of factorization terms. Takes effect if <code>factors_init_method</code> is set to <code>uniform</code>.</p> <p><b>Optional</b></p> <p>Valid values: Non-negative float. Suggested value range: [1e-8, 512].</p> <p>Default value: None</p>
factors_init_sigma	<p>The standard deviation for initialization of factorization terms. Takes effect if <code>factors_init_method</code> is set to <code>normal</code>.</p> <p><b>Optional</b></p> <p>Valid values: Non-negative float. Suggested value range: [1e-8, 512].</p> <p>Default value: 0.001</p>

Parameter Name	Description
<code>factors_init_value</code>	<p>The initial value of factorization terms. Takes effect if <code>factors_init_method</code> is set to <code>constant</code>.</p> <p><b>Optional</b></p> <p>Valid values: Float. Suggested value range: [1e-8, 512].</p> <p>Default value: None</p>
<code>factors_lr</code>	<p>The learning rate for factorization terms.</p> <p><b>Optional</b></p> <p>Valid values: Non-negative float. Suggested value range: [1e-8, 512].</p> <p>Default value: 0.0001</p>
<code>factors_wd</code>	<p>The weight decay for factorization terms.</p> <p><b>Optional</b></p> <p>Valid values: Non-negative float. Suggested value range: [1e-8, 512].</p> <p>Default value: 0.00001</p>
<code>linear_lr</code>	<p>The learning rate for linear terms.</p> <p><b>Optional</b></p> <p>Valid values: Non-negative float. Suggested value range: [1e-8, 512].</p> <p>Default value: 0.001</p>
<code>linear_init_method</code>	<p>The initialization method for linear terms:</p> <ul style="list-style-type: none"> <li><code>normal</code> Initializes weights with random values sampled from a normal distribution with a mean of zero and standard deviation specified by <code>linear_init_sigma</code>.</li> <li><code>uniform</code> Initializes weights with random values uniformly sampled from a range specified by <code>[-linear_init_scale, +linear_init_scale]</code>.</li> <li><code>constant</code> Initializes the weights to a scalar value specified by <code>linear_init_value</code>.</li> </ul> <p><b>Optional</b></p> <p>Valid values: <code>uniform</code>, <code>normal</code>, or <code>constant</code>.</p> <p>Default value: <code>normal</code></p>

Parameter Name	Description
<code>linear_init_scale</code>	<p>Range for initialization of linear terms. Takes effect if <code>linear_init_method</code> is set to <code>uniform</code>.</p> <p><b>Optional</b></p> <p>Valid values: Non-negative float. Suggested value range: [1e-8, 512].</p> <p>Default value: None</p>
<code>linear_init_sigma</code>	<p>The standard deviation for initialization of linear terms. Takes effect if <code>linear_init_method</code> is set to <code>normal</code>.</p> <p><b>Optional</b></p> <p>Valid values: Non-negative float. Suggested value range: [1e-8, 512].</p> <p>Default value: 0.01</p>
<code>linear_init_value</code>	<p>The initial value of linear terms. Takes effect if <code>linear_init_method</code> is set to <code>constant</code>.</p> <p><b>Optional</b></p> <p>Valid values: Float. Suggested value range: [1e-8, 512].</p> <p>Default value: None</p>
<code>linear_wd</code>	<p>The weight decay for linear terms.</p> <p><b>Optional</b></p> <p>Valid values: Non-negative float. Suggested value range: [1e-8, 512].</p> <p>Default value: 0.001</p>
<code>mini_batch_size</code>	<p>The size of mini-batch used for training.</p> <p><b>Optional</b></p> <p>Valid values: Positive integer</p> <p>Default value: 1000</p>
<code>rescale_grad</code>	<p>Gradient rescaling optimizer parameter. If set, multiplies the gradient with <code>rescale_grad</code> before updating. Often choose to be 1.0/batch_size.</p> <p><b>Optional</b></p> <p>Valid values: Float</p> <p>Default value: None</p>

## Tune a Factorization Machines Model

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker \(p. 1745\)](#).

### Metrics Computed by the Factorization Machines Algorithm

The Factorization Machines algorithm has both binary classification and regression predictor types. The predictor type determines which metric you can use for automatic model tuning. The algorithm reports a `test:rmse` regressor metric, which is computed during training. When tuning the model for regression tasks, choose this metric as the objective.

Metric Name	Description	Optimization Direction
<code>test:rmse</code>	Root Mean Square Error	Minimize

The Factorization Machines algorithm reports three binary classification metrics, which are computed during training. When tuning the model for binary classification tasks, choose one of these as the objective.

Metric Name	Description	Optimization Direction
<code>test:binary_classifier_accuracy</code>	Accuracy	Maximize
<code>test:binary_classifier_cross_entropy</code>	Cross entropy	Minimize
<code>test:binary_f_beta</code>	Beta	Maximize

### Tunable Factorization Machines Hyperparameters

You can tune the following hyperparameters for the Factorization Machines algorithm. The initialization parameters that contain the terms bias, linear, and factorization depend on their initialization method. There are three initialization methods: `uniform`, `normal`, and `constant`. These initialization methods are not themselves tunable. The parameters that are tunable are dependent on this choice of the initialization method. For example, if the initialization method is `uniform`, then only the `scale` parameters are tunable. Specifically, if `bias_init_method==uniform`, then `bias_init_scale`, `linear_init_scale`, and `factors_init_scale` are tunable. Similarly, if the initialization method is `normal`, then only `sigma` parameters are tunable. If the initialization method is `constant`, then only `value` parameters are tunable. These dependencies are listed in the following table.

Parameter Name	Parameter Type	Recommended Ranges	Dependency
<code>bias_init_scale</code>	ContinuousParameterRange	MinValue: 1e-8, MaxValue: 512	<code>bias_init_method==uniform</code>
<code>bias_init_sigma</code>	ContinuousParameterRange	MinValue: 1e-8, MaxValue: 512	<code>bias_init_method==normal</code>

Parameter Name	Parameter Type	Recommended Ranges	Dependency
bias_init_value	ContinuousParameterRange	MinValue: 1e-8, MaxValue: 512	bias_init_method==constant
bias_lr	ContinuousParameterRange	MinValue: 1e-8, MaxValue: 512	None
bias_wd	ContinuousParameterRange	MinValue: 1e-8, MaxValue: 512	None
epoch	IntegerParameterRange	MinValue: 1, MaxValue: 1000	None
factors_init_scale	ContinuousParameterRange	MinValue: 1e-8, MaxValue: 512	bias_init_method==uniform
factors_init_sigma	ContinuousParameterRange	MinValue: 1e-8, MaxValue: 512	bias_init_method==normal
factors_init_value	ContinuousParameterRange	MinValue: 1e-8, MaxValue: 512	bias_init_method==constant
factors_lr	ContinuousParameterRange	MinValue: 1e-8, MaxValue: 512	None
factors_wd	ContinuousParameterRange	MinValue: 1e-8, MaxValue: 512]	None
linear_init_scale	ContinuousParameterRange	MinValue: 1e-8, MaxValue: 512	bias_init_method==uniform
linear_init_sigma	ContinuousParameterRange	MinValue: 1e-8, MaxValue: 512	bias_init_method==normal
linear_init_value	ContinuousParameterRange	MinValue: 1e-8, MaxValue: 512	bias_init_method==constant
linear_lr	ContinuousParameterRange	MinValue: 1e-8, MaxValue: 512	None
linear_wd	ContinuousParameterRange	MinValue: 1e-8, MaxValue: 512	None
mini_batch_size	IntegerParameterRange	MinValue: 100, MaxValue: 10000	None

## Factorization Machines Response Formats

### JSON Response Format

Binary classification

```
let response = {
  "predictions": [
    {
      "score": 0.4,
      "predicted_label": 0
    }
  ]
}
```

```
    ]  
}
```

## Regression

```
let response = {  
    "predictions": [  
        {  
            "score": 0.4  
        }  
    ]  
}
```

## JSONLINES Response Format

### Binary classification

```
{"score": 0.4, "predicted_label": 0}
```

### Regression

```
{"score": 0.4}
```

## RECORDIO Response Format

### Binary classification

```
[  
    Record = {  
        features = {},  
        label = {  
            'score': {  
                keys: [],  
                values: [0.4] # float32  
            },  
            'predicted_label': {  
                keys: [],  
                values: [0.0] # float32  
            }  
        }  
    }  
]
```

### Regression

```
[  
    Record = {  
        features = {},  
        label = {  
            'score': {  
                keys: [],  
                values: [0.4] # float32  
            }  
        }  
    }  
]
```

## Image Classification Algorithm

The Amazon SageMaker image classification algorithm is a supervised learning algorithm that supports multi-label classification. It takes an image as input and outputs one or more labels assigned to that image. It uses a convolutional neural network (ResNet) that can be trained from scratch or trained using transfer learning when a large number of training images are not available.

The recommended input format for the Amazon SageMaker image classification algorithms is Apache MXNet [RecordIO](#). However, you can also use raw images in .jpg or .png format. Refer to [this discussion](#) for a broad overview of efficient data preparation and loading for machine learning systems.

**Note**

To maintain better interoperability with existing deep learning frameworks, this differs from the protobuf data formats commonly used by other Amazon SageMaker algorithms.

For more information on convolutional networks, see:

- [Deep residual learning for image recognition](#) Kaiming He, et al., 2016 IEEE Conference on Computer Vision and Pattern Recognition

## Input/Output Interface for the Image Classification Algorithm

The SageMaker Image Classification algorithm supports both RecordIO (`application/x-recordio`) and image (`image/png`, `image/jpeg`, and `application/x-image`) content types for training in file mode, and supports the RecordIO (`application/x-recordio`) content type for training in pipe mode. However, you can also train in pipe mode using the image files (`image/png`, `image/jpeg`, and `application/x-image`), without creating RecordIO files, by using the augmented manifest format.

Distributed training is supported for file mode and pipe mode. When using the RecordIO content type in pipe mode, you must set the `S3DataDistributionType` of the `S3DataSource` to `FullyReplicated`. The algorithm supports a fully replicated model where your data is copied onto each machine.

The algorithm supports `image/png`, `image/jpeg`, and `application/x-image` for inference.

### Train with RecordIO Format

If you use the RecordIO format for training, specify both `train` and `validation` channels as values for the `InputDataConfig` parameter of the [`CreateTrainingJob`](#) request. Specify one RecordIO (`.rec`) file in the `train` channel and one RecordIO file in the `validation` channel. Set the content type for both channels to `application/x-recordio`.

### Train with Image Format

If you use the Image format for training, specify `train`, `validation`, `train_lst`, and `validation_lst` channels as values for the `InputDataConfig` parameter of the [`CreateTrainingJob`](#) request. Specify the individual image data (`.jpg` or `.png` files) for the `train`

and validation channels. Specify one .lst file in each of the `train_lst` and `validation_lst` channels. Set the content type for all four channels to `application/x-image`.

**Note**

SageMaker reads the training and validation data separately from different channels, so you must store the training and validation data in different folders.

A .lst file is a tab-separated file with three columns that contains a list of image files. The first column specifies the image index, the second column specifies the class label index for the image, and the third column specifies the relative path of the image file. The image index in the first column must be unique across all of the images. The set of class label indices are numbered successively and the numbering should start with 0. For example, 0 for the cat class, 1 for the dog class, and so on for additional classes.

The following is an example of a .lst file:

```
5      1    your_image_directory/train_img_dog1.jpg
1000   0    your_image_directory/train_img_cat1.jpg
22     1    your_image_directory/train_img_dog2.jpg
```

For example, if your training images are stored in `s3://<your_bucket>/train/class_dog`, `s3://<your_bucket>/train/class_cat`, and so on, specify the path for your train channel as `s3://<your_bucket>/train`, which is the top-level directory for your data. In the .lst file, specify the relative path for an individual file named `train_image_dog1.jpg` in the `class_dog` class directory as `class_dog/train_image_dog1.jpg`. You can also store all your image files under one subdirectory inside the `train` directory. In that case, use that subdirectory for the relative path. For example, `s3://<your_bucket>/train/your_image_directory`.

### Train with Augmented Manifest Image Format

The augmented manifest format enables you to do training in Pipe mode using image files without needing to create RecordIO files. You need to specify both train and validation channels as values for the `InputDataConfig` parameter of the `CreateTrainingJob` request. While using the format, an S3 manifest file needs to be generated that contains the list of images and their corresponding annotations. The manifest file format should be in [JSON Lines](#) format in which each line represents one sample. The images are specified using the '`source-ref`' tag that points to the S3 location of the image. The annotations are provided under the "`AttributeNames`" parameter value as specified in the `CreateTrainingJob` request. It can also contain additional metadata under the `metadata` tag, but these are ignored by the algorithm. In the following example, the "`AttributeNames`" are contained in the list of image and annotation references `["source-ref", "class"]`. The corresponding label value is "0" for the first image and "1" for the second image:

```
{"source-ref": "s3://image/filename1.jpg", "class": "0"}
{"source-ref": "s3://image/filename2.jpg", "class": "1", "class-metadata": {"class-name": "cat", "type" : "groundtruth/image-classification"}}
```

The order of "`AttributeNames`" in the input files matters when training the `ImageClassification` algorithm. It accepts piped data in a specific order, with `image` first, followed by `label`. So the "`AttributeNames`" in this example are provided with "`source-ref`" first, followed by "`class`". When using the `ImageClassification` algorithm with Augmented Manifest, the value of the `RecordWrapperType` parameter must be "`RecordIO`".

Multi-label training is also supported by specifying a JSON array of values. The `num_classes` hyperparameter must be set to match the total number of classes. There are two valid label formats: multi-hot and class-id.

In the multi-hot format, each label is a multi-hot encoded vector of all classes, where each class takes the value of 0 or 1. In the following example, there are three classes. The first image is labeled with classes 0 and 2, while the second image is labeled with class 2 only:

```
{"image-ref": "s3://mybucket/sample01/image1.jpg", "class": "[1, 0, 1]"}  
 {"image-ref": "s3://mybucket/sample02/image2.jpg", "class": "[0, 0, 1]"}
```

In the class-id format, each label is a list of the class ids, from [0, num\_classes), which apply to the data point. The previous example would instead look like this:

```
{"image-ref": "s3://mybucket/sample01/image1.jpg", "class": "[0, 2]"}  
 {"image-ref": "s3://mybucket/sample02/image2.jpg", "class": "[2]"}
```

The multi-hot format is the default, but can be explicitly set in the content type with the `label-format` parameter: "application/x-recordio; label-format=multi-hot". The class-id format, which is the format outputted by `GroundTruth`, must be set explicitly: "application/x-recordio; label-format=class-id".

For more information on augmented manifest files, see [Provide Dataset Metadata to Training Jobs with an Augmented Manifest File \(p. 1864\)](#).

### Incremental Training

You can also seed the training of a new model with the artifacts from a model that you trained previously with SageMaker. Incremental training saves training time when you want to train a new model with the same or similar data. SageMaker image classification models can be seeded only with another built-in image classification model trained in SageMaker.

To use a pretrained model, in the `CreateTrainingJob` request, specify the `ChannelName` as "model" in the `InputDataConfig` parameter. Set the `ContentType` for the model channel to `application/x-sagemaker-model`. The input hyperparameters of both the new model and the pretrained model that you upload to the model channel must have the same settings for the `num_layers`, `image_shape` and `num_classes` input parameters. These parameters define the network architecture. For the pretrained model file, use the compressed model artifacts (in .tar.gz format) output by SageMaker. You can use either RecordIO or image formats for input data.

For a sample notebook that shows how to use incremental training with the SageMaker image classification algorithm, see the [End-to-End Incremental Training Image Classification Example](#). For more information on incremental training and for instructions on how to use it, see [Incremental Training in Amazon SageMaker \(p. 1855\)](#).

### Inference with the Image Classification Algorithm

The generated models can be hosted for inference and support encoded .jpg and .png image formats as `image/png`, `image/jpeg`, and `application/x-image` content-type. The input image is resized automatically. The output is the probability values for all classes encoded in JSON format, or in [JSON Lines text format](#) for batch transform. The image classification model processes a single image per request and so outputs only one line in the JSON or JSON Lines format. The following is an example of a response in JSON Lines format:

```
accept: application/jsonlines  
  
{"prediction": [prob_0, prob_1, prob_2, prob_3, ...]}
```

For more details on training and inference, see the image classification sample notebook instances referenced in the introduction.

### EC2 Instance Recommendation for the Image Classification Algorithm

For image classification, we support the following GPU instances for training: `m1.p2.xlarge`, `m1.p2.8xlarge`, `m1.p2.16xlarge`, `m1.p3.2xlarge`, `m1.p3.8xlarge` and `m1.p3.16xlarge`. We recommend using GPU instances with more memory for training with large batch sizes. However, both

CPU (such as C4) and GPU (such as P2 and P3) instances can be used for the inference. You can also run the algorithm on multi-GPU and multi-machine settings for distributed training.

Both P2 and P3 instances are supported in the image classification algorithm.

## Image Classification Sample Notebooks

For a sample notebook that uses the SageMaker image classification algorithm to train a model on the [caltech-256 dataset](#) and then to deploy it to perform inferences, see the [End-to-End Multiclass Image Classification Example](#). For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see [Use Amazon SageMaker Notebook Instances \(p. 120\)](#). Once you have created a notebook instance and opened it, select the **SageMaker Examples** tab to see a list of all the SageMaker samples. The example image classification notebooks are located in the **Introduction to Amazon algorithms** section. To open a notebook, click on its **Use** tab and select **Create copy**.

## How Image Classification Works

The image classification algorithm takes an image as input and classifies it into one of the output categories. Deep learning has revolutionized the image classification domain and has achieved great performance. Various deep learning networks such as ResNet [1], DenseNet, inception, and so on, have been developed to be highly accurate for image classification. At the same time, there have been efforts to collect labeled image data that are essential for training these networks. ImageNet[2] is one such large dataset that has more than 11 million images with about 11,000 categories. Once a network is trained with ImageNet data, it can then be used to generalize with other datasets as well, by simple re-adjustment or fine-tuning. In this transfer learning approach, a network is initialized with weights (in this example, trained on ImageNet), which can be later fine-tuned for an image classification task in a different dataset.

Image classification in Amazon SageMaker can be run in two modes: full training and transfer learning. In full training mode, the network is initialized with random weights and trained on user data from scratch. In transfer learning mode, the network is initialized with pre-trained weights and just the top fully connected layer is initialized with random weights. Then, the whole network is fine-tuned with new data. In this mode, training can be achieved even with a smaller dataset. This is because the network is already trained and therefore can be used in cases without sufficient training data.

## Image Classification Hyperparameters

Hyperparameters are parameters that are set before a machine learning model begins learning. The following hyperparameters are supported by the Amazon SageMaker built-in Image Classification algorithm. See [Tune an Image Classification Model \(p. 1409\)](#) for information on image classification hyperparameter tuning.

Parameter Name	Description
num_classes	<p>Number of output classes. This parameter defines the dimensions of the network output and is typically set to the number of classes in the dataset.</p> <p>Besides multi-class classification, multi-label classification is supported too. Please refer to <a href="#">Input/Output Interface for the Image Classification Algorithm (p. 1399)</a> for details on how to work with multi-label classification with augmented manifest files.</p> <p><b>Required</b></p> <p>Valid values: positive integer</p>
num_training_samples	Number of training examples in the input dataset.

Parameter Name	Description
	<p>If there is a mismatch between this value and the number of samples in the training set, then the behavior of the <code>lr_scheduler_step</code> parameter is undefined and distributed training accuracy might be affected.</p> <p><b>Required</b></p> <p>Valid values: positive integer</p>
<code>augmentation_type</code>	<p>Data augmentation type. The input images can be augmented in multiple ways as specified below.</p> <ul style="list-style-type: none"> <li>• <code>crop</code>: Randomly crop the image and flip the image horizontally</li> <li>• <code>crop_color</code>: In addition to '<code>crop</code>', three random values in the range [-36, 36], [-50, 50], and [-50, 50] are added to the corresponding Hue-Saturation-Lightness channels respectively</li> <li>• <code>crop_color_transform</code>: In addition to <code>crop_color</code>, random transformations, including rotation, shear, and aspect ratio variations are applied to the image. The maximum angle of rotation is 10 degrees, the maximum shear ratio is 0.1, and the maximum aspect changing ratio is 0.25.</li> </ul> <p><b>Optional</b></p> <p>Valid values: <code>crop</code>, <code>crop_color</code>, or <code>crop_color_transform</code>.</p> <p>Default value: no default value</p>
<code>beta_1</code>	<p>The beta1 for adam, that is the exponential decay rate for the first moment estimates.</p> <p><b>Optional</b></p> <p>Valid values: float. Range in [0, 1].</p> <p>Default value: 0.9</p>
<code>beta_2</code>	<p>The beta2 for adam, that is the exponential decay rate for the second moment estimates.</p> <p><b>Optional</b></p> <p>Valid values: float. Range in [0, 1].</p> <p>Default value: 0.999</p>

Parameter Name	Description
<code>checkpoint_frequency</code>	<p>Period to store model parameters (in number of epochs). Note that all checkpoint files are saved as part of the final model file "model.tar.gz" and uploaded to S3 to the specified model location. This increases the size of the model file proportionally to the number of checkpoints saved during training.</p> <p><b>Optional</b></p> <p>Valid values: positive integer no greater than epochs.</p> <p>Default value: no default value (Save checkpoint at the epoch that has the best validation accuracy)</p>
<code>early_stopping</code>	<p>True to use early stopping logic during training. False not to use it.</p> <p><b>Optional</b></p> <p>Valid values: True or False</p> <p>Default value: False</p>
<code>early_stopping_min_epochs</code>	<p>The minimum number of epochs that must be run before the early stopping logic can be invoked. It is used only when <code>early_stopping = True</code>.</p> <p><b>Optional</b></p> <p>Valid values: positive integer</p> <p>Default value: 10</p>
<code>early_stopping_patience</code>	<p>The number of epochs to wait before ending training if no improvement is made in the relevant metric. It is used only when <code>early_stopping = True</code>.</p> <p><b>Optional</b></p> <p>Valid values: positive integer</p> <p>Default value: 5</p>
<code>early_stopping_tolerance</code>	<p>Relative tolerance to measure an improvement in accuracy validation metric. If the ratio of the improvement in accuracy divided by the previous best accuracy is smaller than the <code>early_stopping_tolerance</code> value set, early stopping considers there is no improvement. It is used only when <code>early_stopping = True</code>.</p> <p><b>Optional</b></p> <p>Valid values: <math>0 \leq \text{float} \leq 1</math></p> <p>Default value: 0.0</p>

Parameter Name	Description
epochs	<p>Number of training epochs.</p> <p><b>Optional</b></p> <p>Valid values: positive integer</p> <p>Default value: 30</p>
eps	<p>The epsilon for adam and rmsprop. It is usually set to a small value to avoid division by 0.</p> <p><b>Optional</b></p> <p>Valid values: float. Range in [0, 1].</p> <p>Default value: 1e-8</p>
gamma	<p>The gamma for rmsprop, the decay factor for the moving average of the squared gradient.</p> <p><b>Optional</b></p> <p>Valid values: float. Range in [0, 1].</p> <p>Default value: 0.9</p>
image_shape	<p>The input image dimensions, which is the same size as the input layer of the network. The format is defined as 'num_channels, height, width'. The image dimension can take on any value as the network can handle varied dimensions of the input. However, there may be memory constraints if a larger image dimension is used. Pretrained models can use only a fixed 224 x 224 image size. Typical image dimensions for image classification are '3, 224, 224'. This is similar to the ImageNet dataset.</p> <p>For training, if any input image is smaller than this parameter in any dimension, training fails. If an image is larger, a portion of the image is cropped, with the cropped area specified by this parameter. If hyperparameter augmentation_type is set, random crop is taken; otherwise, central crop is taken.</p> <p>At inference, input images are resized to the image_shape that was used during training. Aspect ratio is not preserved, and images are not cropped.</p> <p><b>Optional</b></p> <p>Valid values: string</p> <p>Default value: '3, 224, 224'</p>

Parameter Name	Description
<code>kv_store</code>	<p>Weight update synchronization mode during distributed training. The weight updates can be updated either synchronously or asynchronously across machines. Synchronous updates typically provide better accuracy than asynchronous updates but can be slower. See <a href="#">distributed training in MXNet</a> for more details.</p> <p>This parameter is not applicable to single machine training.</p> <ul style="list-style-type: none"> <li>• <code>dist_sync</code>: The gradients are synchronized after every batch with all the workers. With <code>dist_sync</code>, batch-size now means the batch size used on each machine. So if there are n machines and we use batch size b, then <code>dist_sync</code> behaves like local with batch size <math>n \times b</math></li> <li>• <code>dist_async</code>: Performs asynchronous updates. The weights are updated whenever gradients are received from any machine and the weight updates are atomic. However, the order is not guaranteed.</li> </ul> <p><b>Optional</b></p> <p>Valid values: <code>dist_sync</code> or <code>dist_async</code></p> <p>Default value: no default value</p>
<code>learning_rate</code>	<p>Initial learning rate.</p> <p><b>Optional</b></p> <p>Valid values: float. Range in [0, 1].</p> <p>Default value: 0.1</p>
<code>lr_scheduler_factor</code>	<p>The ratio to reduce learning rate used in conjunction with the <code>lr_scheduler_step</code> parameter, defined as <math>lr_{new} = lr_{old} * lr\_scheduler\_factor</math>.</p> <p><b>Optional</b></p> <p>Valid values: float. Range in [0, 1].</p> <p>Default value: 0.1</p>
<code>lr_scheduler_step</code>	<p>The epochs at which to reduce the learning rate. As explained in the <code>lr_scheduler_factor</code> parameter, the learning rate is reduced by <code>lr_scheduler_factor</code> at these epochs. For example, if the value is set to "10, 20", then the learning rate is reduced by <code>lr_scheduler_factor</code> after 10th epoch and again by <code>lr_scheduler_factor</code> after 20th epoch. The epochs are delimited by ",".</p> <p><b>Optional</b></p> <p>Valid values: string</p> <p>Default value: no default value</p>

Parameter Name	Description
<code>mini_batch_size</code>	<p>The batch size for training. In a single-machine multi-GPU setting, each GPU handles <code>mini_batch_size/num_gpu</code> training samples. For the multi-machine training in <code>dist_sync</code> mode, the actual batch size is <code>mini_batch_size*number of machines</code>. See MXNet docs for more details.</p> <p><b>Optional</b></p> <p>Valid values: positive integer</p> <p>Default value: 32</p>
<code>momentum</code>	<p>The momentum for <code>sgd</code> and <code>nag</code>, ignored for other optimizers.</p> <p><b>Optional</b></p> <p>Valid values: float. Range in [0, 1].</p> <p>Default value: 0.9</p>
<code>multi_label</code>	<p>Flag to use for multi-label classification where each sample can be assigned multiple labels. Average accuracy across all classes is logged.</p> <p><b>Optional</b></p> <p>Valid values: 0 or 1</p> <p>Default value: 0</p>
<code>num_layers</code>	<p>Number of layers for the network. For data with large image size (for example, 224x224 - like ImageNet), we suggest selecting the number of layers from the set [18, 34, 50, 101, 152, 200]. For data with small image size (for example, 28x28 - like CIFAR), we suggest selecting the number of layers from the set [20, 32, 44, 56, 110]. The number of layers in each set is based on the ResNet paper. For transfer learning, the number of layers defines the architecture of base network and hence can only be selected from the set [18, 34, 50, 101, 152, 200].</p> <p><b>Optional</b></p> <p>Valid values: positive integer in [18, 34, 50, 101, 152, 200] or [20, 32, 44, 56, 110]</p> <p>Default value: 152</p>

Parameter Name	Description
optimizer	<p>The optimizer type. For more details of the parameters for the optimizers, please refer to MXNet's API.</p> <p><b>Optional</b></p> <p>Valid values: One of <code>sgd</code>, <code>adam</code>, <code>rmsprop</code>, or <code>nag</code>.</p> <ul style="list-style-type: none"> <li>• <code>sgd</code>: <a href="#">Stochastic gradient descent</a></li> <li>• <code>adam</code>: <a href="#">Adaptive momentum estimation</a></li> <li>• <code>rmsprop</code>: <a href="#">Root mean square propagation</a></li> <li>• <code>nag</code>: <a href="#">Nesterov accelerated gradient</a></li> </ul> <p>Default value: <code>sgd</code></p>
precision_dtype	<p>The precision of the weights used for training. The algorithm can use either single precision (<code>float32</code>) or half precision (<code>float16</code>) for the weights. Using half-precision for weights results in reduced memory consumption.</p> <p><b>Optional</b></p> <p>Valid values: <code>float32</code> or <code>float16</code></p> <p>Default value: <code>float32</code></p>
resize	<p>The number of pixels in the shortest side of an image after resizing it for training. If the parameter is not set, then the training data is used without resizing. The parameter should be larger than both the width and height components of <code>image_shape</code> to prevent training failure.</p> <p><b>Required</b> when using image content types</p> <p><b>Optional</b> when using the RecordIO content type</p> <p>Valid values: positive integer</p> <p>Default value: no default value</p>
top_k	<p>Reports the top-k accuracy during training. This parameter has to be greater than 1, since the top-1 training accuracy is the same as the regular training accuracy that has already been reported.</p> <p><b>Optional</b></p> <p>Valid values: positive integer larger than 1.</p> <p>Default value: no default value</p>

Parameter Name	Description
<code>use_pretrained_model</code>	<p>Flag to use pre-trained model for training. If set to 1, then the pretrained model with the corresponding number of layers is loaded and used for training. Only the top FC layer are reinitialized with random weights. Otherwise, the network is trained from scratch.</p> <p><b>Optional</b></p> <p>Valid values: 0 or 1</p> <p>Default value: 0</p>
<code>use_weighted_loss</code>	<p>Flag to use weighted cross-entropy loss for multi-label classification (used only when <code>multi_label</code> = 1), where the weights are calculated based on the distribution of classes.</p> <p><b>Optional</b></p> <p>Valid values: 0 or 1</p> <p>Default value: 0</p>
<code>weight_decay</code>	<p>The coefficient weight decay for <code>sgd</code> and <code>nag</code>, ignored for other optimizers.</p> <p><b>Optional</b></p> <p>Valid values: float. Range in [0, 1].</p> <p>Default value: 0.0001</p>

## Tune an Image Classification Model

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker \(p. 1745\)](#).

### Metrics Computed by the Image Classification Algorithm

The image classification algorithm is a supervised algorithm. It reports an accuracy metric that is computed during training. When tuning the model, choose this metric as the objective metric.

Metric Name	Description	Optimization Direction
<code>validation:accuracy</code>	The ratio of the number of correct predictions to the total number of predictions made.	Maximize

### Tunable Image Classification Hyperparameters

Tune an image classification model with the following hyperparameters. The hyperparameters that have the greatest impact on image classification objective metrics are: `mini_batch_size`, `learning_rate`,

and `optimizer`. Tune the optimizer-related hyperparameters, such as `momentum`, `weight_decay`, `beta_1`, `beta_2`, `eps`, and `gamma`, based on the selected `optimizer`. For example, use `beta_1` and `beta_2` only when `adam` is the optimizer.

For more information about which hyperparameters are used in each optimizer, see [Image Classification Hyperparameters \(p. 1402\)](#).

Parameter Name	Parameter Type	Recommended Ranges
<code>beta_1</code>	ContinuousParameterRanges	MinValue: 1e-6, MaxValue: 0.999
<code>beta_2</code>	ContinuousParameterRanges	MinValue: 1e-6, MaxValue: 0.999
<code>eps</code>	ContinuousParameterRanges	MinValue: 1e-8, MaxValue: 1.0
<code>gamma</code>	ContinuousParameterRanges	MinValue: 1e-8, MaxValue: 0.999
<code>learning_rate</code>	ContinuousParameterRanges	MinValue: 1e-6, MaxValue: 0.5
<code>mini_batch_size</code>	IntegerParameterRanges	MinValue: 8, MaxValue: 512
<code>momentum</code>	ContinuousParameterRanges	MinValue: 0.0, MaxValue: 0.999
<code>optimizer</code>	CategoricalParameterRanges	['sgd', 'adam', 'rmsprop', 'nag']
<code>weight_decay</code>	ContinuousParameterRanges	MinValue: 0.0, MaxValue: 0.999

## IP Insights

Amazon SageMaker IP Insights is an unsupervised learning algorithm that learns the usage patterns for IPv4 addresses. It is designed to capture associations between IPv4 addresses and various entities, such as user IDs or account numbers. You can use it to identify a user attempting to log into a web service from an anomalous IP address, for example. Or you can use it to identify an account that is attempting to create computing resources from an unusual IP address. Trained IP Insight models can be hosted at an endpoint for making real-time predictions or used for processing batch transforms.

SageMaker IP insights ingests historical data as (entity, IPv4 Address) pairs and learns the IP usage patterns of each entity. When queried with an (entity, IPv4 Address) event, a SageMaker IP Insights model returns a score that infers how anomalous the pattern of the event is. For example, when a user attempts to log in from an IP address, if the IP Insights score is high enough, a web login server might decide to trigger a multi-factor authentication system. In more advanced solutions, you can feed the IP Insights score into another machine learning model. For example, you can combine the IP Insight score with other features to rank the findings of another security system, such as those from [Amazon GuardDuty](#).

The SageMaker IP Insights algorithm can also learn vector representations of IP addresses, known as *embeddings*. You can use vector-encoded embeddings as features in downstream machine learning tasks that use the information observed in the IP addresses. For example, you can use them in tasks such as measuring similarities between IP addresses in clustering and visualization tasks.

## [Input/Output Interface for the IP Insights Algorithm](#)

### Training and Validation

The SageMaker IP Insights algorithm supports training and validation data channels. It uses the optional validation channel to compute an area-under-curve (AUC) score on a predefined negative sampling strategy. The AUC metric validates how well the model discriminates between positive and negative samples. Training and validation data content types need to be in `text/csv` format. The first column of the CSV data is an opaque string that provides a unique identifier for the entity. The second column is an IPv4 address in decimal-dot notation. IP Insights currently supports only File mode. For more information and some examples, see [IP Insights Training Data Formats \(p. 1417\)](#).

### Inference

For inference, IP Insights supports `text/csv`, `application/json`, and `application/jsonlines` data content types. For more information about the common data formats for inference provided by SageMaker, see [Common Data Formats for Inference \(p. 1358\)](#). IP Insights inference returns output formatted as either `application/json` or `application/jsonlines`. Each record in the output data contains the corresponding `dot_product` (or compatibility score) for each input data point. For more information and some examples, see [IP Insights Inference Data Formats \(p. 1418\)](#).

## [EC2 Instance Recommendation for the IP Insights Algorithm](#)

The SageMaker IP Insights algorithm can run on both GPU and CPU instances. For training jobs, we recommend using GPU instances. However, for certain workloads with large training datasets, distributed CPU instances might reduce training costs. For inference, we recommend using CPU instances.

### [GPU Instances for the IP Insights Algorithm](#)

IP Insights supports all available GPUs. If you need to speed up training, we recommend starting with a single GPU instance, such as `ml.p3.2xlarge`, and then moving to a multi-GPU environment, such as `ml.p3.8xlarge` and `ml.p3.16xlarge`. Multi-GPUs automatically divide the mini batches of training data across themselves. If you switch from a single GPU to multiple GPUs, the `mini_batch_size` is divided equally into the number of GPUs used. You may want to increase the value of the `mini_batch_size` to compensate for this.

### [CPU Instances for the IP Insights Algorithm](#)

The type of CPU instance that we recommend depends largely on the instance's available memory and the model size. The model size is determined by two hyperparameters: `vector_dim` and `num_entity_vectors`. The maximum supported model size is 8 GB. The following table lists typical EC2 instance types that you would deploy based on these input parameters for various model sizes. In Table 1, the value for `vector_dim` in the first column range from 32 to 2048 and the values for `num_entity_vectors` in the first row range from 10,000 to 50,000,000.

<code>vector_d</code>	10,000	50,000	100,000	500,000	1,000,000	5,000,000	10,000,000	50,000,000
\								
<code>num_entities</code>								
32	ml.m5.large	ml.m5.large	ml.m5.large	ml.m5.large	ml.m5.large	ml.m5.xlarge	ml.m5.2xlarge	ml.m5.4xlarge
64	ml.m5.large	ml.m5.large	ml.m5.large	ml.m5.large	ml.m5.large	ml.m5.2xlarge	ml.m5.4xlarge	
128	ml.m5.large	ml.m5.large	ml.m5.large	ml.m5.large	ml.m5.2xlarge	ml.m5.4xlarge		
256	ml.m5.large	ml.m5.large	ml.m5.large	ml.m5.large	ml.m5.xlarge	ml.m5.4xlarge		
512	ml.m5.large	ml.m5.large	ml.m5.large	ml.m5.2xlarge				
1024	ml.m5.large	ml.m5.large	ml.m5.xlarge	ml.m5.4xlarge				
2048	ml.m5.large	ml.m5.xlarge	ml.m5.xlarge					

The values for the `mini_batch_size`, `num_ip_encoder_layers`, `random_negative_sampling_rate`, and `shuffled_negative_sampling_rate` hyperparameters also affect the amount of memory required. If these values are large, you might need to use a larger instance type than normal.

## IP Insights Sample Notebooks

For a sample notebook that shows how to train the SageMaker IP Insights algorithm and perform inferences with it, see [An Introduction to the SageMaker IP Insights Algorithm](#). For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see [Use Amazon SageMaker Notebook Instances \(p. 120\)](#). After creating a notebook instance, choose the **SageMaker Examples** tab to see a list of all the SageMaker examples. To open a notebook, choose its **Use** tab and choose **Create copy**.

## How IP Insights Works

Amazon SageMaker IP Insights is an unsupervised algorithm that consumes observed data in the form of (entity, IPv4 address) pairs that associates entities with IP addresses. IP Insights determines how likely it is that an entity would use a particular IP address by learning latent vector representations for both entities and IP addresses. The distance between these two representations can then serve as the proxy for how likely this association is.

The IP Insights algorithm uses a neural network to learn the latent vector representations for entities and IP addresses. Entities are first hashed to a large but fixed hash space and then encoded by a simple embedding layer. Character strings such as user names or account IDs can be fed directly into IP Insights as they appear in log files. You don't need to preprocess the data for entity identifiers. You can provide entities as an arbitrary string value during both training and inference. The hash size should be configured with a value that is high enough to insure that the number of *collisions*, which occur when distinct entities are mapped to the same latent vector, remain insignificant. For more information about how to select appropriate hash sizes, see [Feature Hashing for Large Scale Multitask Learning](#). For representing IP addresses, on the other hand, IP Insights uses a specially designed encoder network to uniquely represent each possible IPv4 address by exploiting the prefix structure of IP addresses.

During training, IP Insights automatically generates negative samples by randomly pairing entities and IP addresses. These negative samples represent data that is less likely to occur in reality. The model is trained to discriminate between positive samples that are observed in the training data and these generated negative samples. More specifically, the model is trained to minimize the *cross entropy*, also known as the *log loss*, defined as follows:

$$L = \frac{1}{N} \sum_n [y_n \log p_n + (1 - y_n) \log (1 - p_n)]$$

$y_n$  is the label that indicates whether the sample is from the real distribution governing observed data ( $y_n=1$ ) or from the distribution generating negative samples ( $y_n=0$ ).  $p_n$  is the probability that the sample is from the real distribution, as predicted by the model.

Generating negative samples is an important process that is used to achieve an accurate model of the observed data. If negative samples are extremely unlikely, for example, if all of the IP addresses in negative samples are 10.0.0.0, then the model trivially learns to distinguish negative samples and fails to accurately characterize the actual observed dataset. To keep negative samples more realistic, IP Insights generates negative samples both by randomly generating IP addresses and randomly picking IP addresses from training data. You can configure the type of negative sampling and the rates at which negative samples are generated with the `random_negative_sampling_rate` and `shuffled_negative_sampling_rate` hyperparameters.

Given an nth (entity, IP address pair), the IP Insights model outputs a *score*,  $S_n$ , that indicates how compatible the entity is with the IP address. This score corresponds to the log odds ratio for a given (entity, IP address) of the pair coming from a real distribution as compared to coming from a negative distribution. It is defined as follows:

$$S_n = \log \left( \frac{P_{\text{real}}(n)}{P_{\text{neg}}(n)} \right)$$

The score is essentially a measure of the similarity between the vector representations of the nth entity and IP address. It can be interpreted as how much more likely it would be to observe this event in reality than in a randomly generated dataset. During training, the algorithm uses this score to calculate an estimate of the probability of a sample coming from the real distribution,  $p_n$ , to use in the cross entropy minimization, where:

$$p_n = \frac{1}{1 + e^{-S_n}}$$

## IP Insights Hyperparameters

In the [CreateTransformJob](#) request, you specify the training algorithm. You can also specify algorithm-specific hyperparameters as string-to-string maps. The following table lists the hyperparameters for the Amazon SageMaker IP Insights algorithm.

Parameter Name	Description
<code>num_entity_vectors</code>	<p>The number of entity vector representations (entity embedding vectors) to train. Each entity in the training set is randomly assigned to one of these vectors using a hash function. Because of hash collisions, it might be possible to have multiple entities assigned to the same vector. This would cause the same vector to represent multiple entities. This generally has a negligible effect on model performance, as long as the collision rate is not too severe. To keep the collision rate low, set this value as high as possible. However, the model size, and, therefore, the memory requirement, for both training and inference, scales linearly with this hyperparameter. We recommend that you set this value to twice the number of unique entity identifiers.</p> <p><b>Required</b></p> <p>Valid values: 1 ≤ positive integer ≤ 250,000,000</p>

Parameter Name	Description
vector_dim	<p>The size of embedding vectors to represent entities and IP addresses. The larger the value, the more information that can be encoded using these representations. In practice, model size scales linearly with this parameter and limits how large the dimension can be. In addition, using vector representations that are too large can cause the model to overfit, especially for small training datasets. Overfitting occurs when a model doesn't learn any pattern in the data but effectively memorizes the training data and, therefore, cannot generalize well and performs poorly during inference. The recommended value is 128.</p> <p><b>Required</b></p> <p>Valid values: 4 ≤ positive integer ≤ 4096</p>
batch_metrics_publish_interval	<p>The interval (every X batches) at which the Apache MXNet Speedometer function prints the training speed of the network (samples/second).</p> <p><b>Optional</b></p> <p>Valid values: positive integer ≥ 1</p> <p>Default value: 1,000</p>
epochs	<p>The number of passes over the training data. The optimal value depends on your data size and learning rate. Typical values range from 5 to 100.</p> <p><b>Optional</b></p> <p>Valid values: positive integer ≥ 1</p> <p>Default value: 10</p>
learning_rate	<p>The learning rate for the optimizer. IP Insights use a gradient-descent-based Adam optimizer. The learning rate effectively controls the step size to update model parameters at each iteration. Too large a learning rate can cause the model to diverge because the training is likely to overshoot a minima. On the other hand, too small a learning rate slows down convergence. Typical values range from 1e-4 to 1e-1.</p> <p><b>Optional</b></p> <p>Valid values: 1e-6 ≤ float ≤ 10.0</p> <p>Default value: 0.001</p>

Parameter Name	Description
<code>mini_batch_size</code>	<p>The number of examples in each mini batch. The training procedure processes data in mini batches. The optimal value depends on the number of unique account identifiers in the dataset. In general, the larger the <code>mini_batch_size</code>, the faster the training and the greater the number of possible shuffled-negative-sample combinations. However, with a large <code>mini_batch_size</code>, the training is more likely to converge to a poor local minimum and perform relatively worse for inference.</p> <p><b>Optional</b></p> <p>Valid values: <math>1 \leq \text{positive integer} \leq 500000</math></p> <p>Default value: 10,000</p>
<code>num_ip_encoder_layers</code>	<p>The number of fully connected layers used to encode the IP address embedding. The larger the number of layers, the greater the model's capacity to capture patterns among IP addresses. However, using a large number of layers increases the chance of overfitting.</p> <p><b>Optional</b></p> <p>Valid values: <math>0 \leq \text{positive integer} \leq 100</math></p> <p>Default value: 1</p>
<code>random_negative_sampling_rate</code>	<p>The number of random negative samples, R, to generate per input example. The training procedure relies on negative samples to prevent the vector representations of the model collapsing to a single point. Random negative sampling generates R random IP addresses for each input account in the mini batch. The sum of the <code>random_negative_sampling_rate</code> (R) and <code>shuffled_negative_sampling_rate</code> (S) must be in the interval: <math>1 \leq R + S \leq 500</math>.</p> <p><b>Optional</b></p> <p>Valid values: <math>0 \leq \text{positive integer} \leq 500</math></p> <p>Default value: 1</p>

Parameter Name	Description
shuffled_negative_sampling_rate	<p>The number of shuffled negative samples, S, to generate per input example. In some cases, it helps to use more realistic negative samples that are randomly picked from the training data itself. This kind of negative sampling is achieved by shuffling the data within a mini batch. Shuffled negative sampling generates S negative IP addresses by shuffling the IP address and account pairings within a mini batch. The sum of the <code>random_negative_sampling_rate</code> (R) and <code>shuffled_negative_sampling_rate</code> (S) must be in the interval: <math>1 \leq R + S \leq 500</math>.</p> <p><b>Optional</b></p> <p>Valid values: <math>0 \leq \text{positive integer} \leq 500</math></p> <p>Default value: 1</p>
weight_decay	<p>The weight decay coefficient. This parameter adds an L2 regularization factor that is required to prevent the model from overfitting the training data.</p> <p><b>Optional</b></p> <p>Valid values: <math>0.0 \leq \text{float} \leq 10.0</math></p> <p>Default value: 0.00001</p>

## Tune an IP Insights Model

*Automatic model tuning*, also called hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker \(p. 1745\)](#).

### Metrics Computed by the IP Insights Algorithm

The Amazon SageMaker IP Insights algorithm is an unsupervised learning algorithm that learns associations between IP addresses and entities. The algorithm trains a discriminator model, which learns to separate observed data points (*positive samples*) from randomly generated data points (*negative samples*). Automatic model tuning on IP Insights helps you find the model that can most accurately distinguish between unlabeled validation data and automatically generated negative samples. The model accuracy on the validation dataset is measured by the area under the receiver operating characteristic curve. This `validation:discriminator_auc` metric can take values between 0.0 and 1.0, where 1.0 indicates perfect accuracy.

The IP Insights algorithm computes a `validation:discriminator_auc` metric during validation, the value of which is used as the objective function to optimize for hyperparameter tuning.

Metric Name	Description	Optimization Direction
validation:discriminability	Area under the receiver operating characteristic curve on the validation dataset. The validation dataset is not labeled. Area Under the Curve (AUC) is a metric that describes the model's ability to discriminate validation data points from randomly generated data points.	Maximize

## Tunable IP Insights Hyperparameters

You can tune the following hyperparameters for the SageMaker IP Insights algorithm.

Parameter Name	Parameter Type	Recommended Ranges
epochs	IntegerParameterRange	MinValue: 1, MaxValue: 100
learning_rate	ContinuousParameterRange	MinValue: 1e-4, MaxValue: 0.1
mini_batch_size	IntegerParameterRanges	MinValue: 100, MaxValue: 50000
num_entity_vectors	IntegerParameterRanges	MinValue: 10000, MaxValue: 1000000
num_ip_encoder_layers	IntegerParameterRanges	MinValue: 1, MaxValue: 10
random_negative_samples	IntegerParameterRanges	MinValue: 0, MaxValue: 10
shuffled_negative_samples	IntegerParameterRanges	MinValue: 0, MaxValue: 10
vector_dim	IntegerParameterRanges	MinValue: 8, MaxValue: 256
weight_decay	ContinuousParameterRange	MinValue: 0.0, MaxValue: 1.0

## IP Insights Data Formats

This section provides examples of the available input and output data formats used by the IP Insights algorithm during training and inference.

### Topics

- [IP Insights Training Data Formats \(p. 1417\)](#)
- [IP Insights Inference Data Formats \(p. 1418\)](#)

### IP Insights Training Data Formats

The following are the available data input formats for the IP Insights algorithm. Amazon SageMaker built-in algorithms adhere to the common input training format described in [Common Data Formats for](#)

[Training \(p. 1354\)](#). However, the SageMaker IP Insights algorithm currently supports only the CSV data input format.

## IP Insights Training Data Input Formats

### INPUT: CSV

The CSV file must have two columns. The first column is an opaque string that corresponds to an entity's unique identifier. The second column is the IPv4 address of the entity's access event in decimal-dot notation.

content-type: text/csv

```
entity_id_1, 192.168.1.2
entity_id_2, 10.10.1.2
```

## IP Insights Inference Data Formats

The following are the available input and output formats for the IP Insights algorithm. Amazon SageMaker built-in algorithms adhere to the common input inference format described in [Common Data Formats for Inference \(p. 1358\)](#). However, the SageMaker IP Insights algorithm does not currently support RecordIO format.

### IP Insights Input Request Formats

#### INPUT: CSV Format

The CSV file must have two columns. The first column is an opaque string that corresponds to an entity's unique identifier. The second column is the IPv4 address of the entity's access event in decimal-dot notation.

content-type: text/csv

```
entity_id_1, 192.168.1.2
entity_id_2, 10.10.1.2
```

#### INPUT: JSON Format

JSON data can be provided in different formats. IP Insights follows the common SageMaker formats. For more information about inference formats, see [Common Data Formats for Inference \(p. 1358\)](#).

content-type: application/json

```
{
  "instances": [
    {"data": {"features": {"values": ["entity_id_1", "192.168.1.2"]}}},
    {"features": ["entity_id_2", "10.10.1.2"]}
  ]
}
```

#### INPUT: JSONLINES Format

The JSON Lines content type is useful for running batch transform jobs. For more information on SageMaker inference formats, see [Common Data Formats for Inference \(p. 1358\)](#). For more information on running batch transform jobs, see [Get Inferences for an Entire Dataset with Batch Transform \(p. 13\)](#).

content-type: application/jsonlines

```
{"data": {"features": {"values": ["entity_id_1", "192.168.1.2"]}}},  
{"features": ["entity_id_2", "10.10.1.2"]}]
```

## IP Insights Output Response Formats

### OUTPUT: JSON Response Format

The default output of the SageMaker IP Insights algorithm is the dot\_product between the input entity and IP address. The dot\_product signifies how compatible the model considers the entity and IP address. The dot\_product is unbounded. To make predictions about whether an event is anomalous, you need to set a threshold based on your defined distribution. For information about how to use the dot\_product for anomaly detection, see the [An Introduction to the SageMakerIP Insights Algorithm](#).

accept: application/json

```
{  
    "predictions": [  
        {"dot_product": 0.0},  
        {"dot_product": 2.0}  
    ]  
}
```

Advanced users can access the model's learned entity and IP embeddings by providing the additional content-type parameter verbose=True to the Accept heading. You can use the entity\_embedding and ip\_embedding for debugging, visualizing, and understanding the model. Additionally, you can use these embeddings in other machine learning techniques, such as classification or clustering.

accept: application/json;verbose=True

```
{  
    "predictions": [  
        {  
            "dot_product": 0.0,  
            "entity_embedding": [1.0, 0.0, 0.0],  
            "ip_embedding": [0.0, 1.0, 0.0]  
        },  
        {  
            "dot_product": 2.0,  
            "entity_embedding": [1.0, 0.0, 1.0],  
            "ip_embedding": [1.0, 0.0, 1.0]  
        }  
    ]  
}
```

### OUTPUT: JSONLINES Response Format

accept: application/jsonlines

```
{"dot_product": 0.0}  
{"dot_product": 2.0}
```

accept: application/jsonlines; verbose=True

```
{"dot_product": 0.0, "entity_embedding": [1.0, 0.0, 0.0], "ip_embedding": [0.0, 1.0, 0.0]}  
{"dot_product": 2.0, "entity_embedding": [1.0, 0.0, 1.0], "ip_embedding": [1.0, 0.0, 1.0]}
```

## K-Means Algorithm

K-means is an unsupervised learning algorithm. It attempts to find discrete groupings within data, where members of a group are as similar as possible to one another and as different as possible from members of other groups. You define the attributes that you want the algorithm to use to determine similarity.

Amazon SageMaker uses a modified version of the web-scale k-means clustering algorithm. Compared with the original version of the algorithm, the version used by Amazon SageMaker is more accurate. Like the original algorithm, it scales to massive datasets and delivers improvements in training time. To do this, the version used by Amazon SageMaker streams mini-batches (small, random subsets) of the training data. For more information about mini-batch k-means, see [Web-scale k-means Clustering](#).

The k-means algorithm expects tabular data, where rows represent the observations that you want to cluster, and the columns represent attributes of the observations. The  $n$  attributes in each row represent a point in  $n$ -dimensional space. The Euclidean distance between these points represents the similarity of the corresponding observations. The algorithm groups observations with similar attribute values (the points corresponding to these observations are closer together). For more information about how k-means works in Amazon SageMaker, see [How K-Means Clustering Works \(p. 1421\)](#).

### Topics

- [Input/Output Interface for the K-Means Algorithm \(p. 1420\)](#)
- [EC2 Instance Recommendation for the K-Means Algorithm \(p. 1420\)](#)
- [K-Means Sample Notebooks \(p. 1420\)](#)
- [How K-Means Clustering Works \(p. 1421\)](#)
- [K-Means Hyperparameters \(p. 1423\)](#)
- [Tune a K-Means Model \(p. 1426\)](#)
- [K-Means Response Formats \(p. 1427\)](#)

## Input/Output Interface for the K-Means Algorithm

For training, the k-means algorithm expects data to be provided in the `train` channel (recommended `S3DataDistributionType=ShardedByS3Key`), with an optional `test` channel (recommended `S3DataDistributionType=FullyReplicated`) to score the data on. Both `recordIO-wrapped-protobuf` and `CSV` formats are supported for training. You can use either File mode or Pipe mode to train models on data that is formatted as `recordIO-wrapped-protobuf` or as `CSV`.

For inference, `text/csv`, `application/json`, and `application/x-recordio-protobuf` are supported. k-means returns a `closest_cluster` label and the `distance_to_cluster` for each observation.

For more information on input and output file formats, see [K-Means Response Formats \(p. 1427\)](#) for inference and the [K-Means Sample Notebooks \(p. 1420\)](#). The k-means algorithm does not support multiple instance learning, in which the training set consists of labeled “bags”, each of which is a collection of unlabeled instances.

## EC2 Instance Recommendation for the K-Means Algorithm

We recommend training k-means on CPU instances. You can train on GPU instances, but should limit GPU training to `p* .xlarge` instances because only one GPU per instance is used.

## K-Means Sample Notebooks

For a sample notebook that uses the SageMaker K-means algorithm to segment the population of counties in the United States by attributes identified using principle component analysis, see [Analyze US census data for population segmentation using Amazon SageMaker](#). For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see [Use Amazon](#)

[SageMaker Notebook Instances \(p. 120\)](#). Once you have created a notebook instance and opened it, select the **SageMaker Examples** tab to see a list of all the SageMaker samples. To open a notebook, click on its **Use** tab and select **Create copy**.

## How K-Means Clustering Works

K-means is an algorithm that trains a model that groups similar objects together. The k-means algorithm accomplishes this by mapping each observation in the input dataset to a point in the  $n$ -dimensional space (where  $n$  is the number of attributes of the observation). For example, your dataset might contain observations of temperature and humidity in a particular location, which are mapped to points  $(t, h)$  in 2-dimensional space.

### Note

Clustering algorithms are unsupervised. In unsupervised learning, labels that might be associated with the objects in the training dataset aren't used.

In k-means clustering, each cluster has a center. During model training, the k-means algorithm uses the distance of the point that corresponds to each observation in the dataset to the cluster centers as the basis for clustering. You choose the number of clusters ( $k$ ) to create.

For example, suppose that you want to create a model to recognize handwritten digits and you choose the MNIST dataset for training. The dataset provides thousands of images of handwritten digits (0 through 9). In this example, you might choose to create 10 clusters, one for each digit (0, 1, ..., 9). As part of model training, the k-means algorithm groups the input images into 10 clusters.

Each image in the MNIST dataset is a 28x28-pixel image, with a total of 784 pixels. Each image corresponds to a point in a 784-dimensional space, similar to a point in a 2-dimensional space  $(x,y)$ . To find a cluster to which a point belongs, the k-means algorithm finds the distance of that point from all of the cluster centers. It then chooses the cluster with the closest center as the cluster to which the image belongs.

### Note

Amazon SageMaker uses a customized version of the algorithm where, instead of specifying that the algorithm create  $k$  clusters, you might choose to improve model accuracy by specifying extra cluster centers ( $K = k*x$ ). However, the algorithm ultimately reduces these to  $k$  clusters.

In SageMaker, you specify the number of clusters when creating a training job. For more information, see [CreateTrainingJob](#). In the request body, you add the `HyperParameters` string map to specify the `k` and `extra_center_factor` strings.

The following is a summary of how k-means works for model training in SageMaker:

1. It determines the initial  $K$  cluster centers.

### Note

In the following topics,  $K$  clusters refer to  $k * x$ , where you specify  $k$  and  $x$  when creating a model training job.

2. It iterates over input training data and recalculates cluster centers.
3. It reduces resulting clusters to  $k$  (if the data scientist specified the creation of  $k*x$  clusters in the request).

The following sections also explain some of the parameters that a data scientist might specify to configure a model training job as part of the `HyperParameters` string map.

### Topics

- [Step 1: Determine the Initial Cluster Centers \(p. 1422\)](#)
- [Step 2: Iterate over the Training Dataset and Calculate Cluster Centers \(p. 1422\)](#)
- [Step 3: Reduce the Clusters from  \$K\$  to  \$k\$  \(p. 1423\)](#)

## Step 1: Determine the Initial Cluster Centers

When using k-means in SageMaker, the initial cluster centers are chosen from the observations in a small, randomly sampled batch. Choose one of the following strategies to determine how these initial cluster centers are selected:

- The random approach—Randomly choose  $K$  observations in your input dataset as cluster centers. For example, you might choose a cluster center that points to the 784-dimensional space that corresponds to any 10 images in the MNIST training dataset.
- The k-means++ approach, which works as follows:
  1. Start with one cluster and determine its center. You randomly select an observation from your training dataset and use the point corresponding to the observation as the cluster center. For example, in the MNIST dataset, randomly choose a handwritten digit image. Then choose the point in the 784-dimensional space that corresponds to the image as your cluster center. This is cluster center 1.
  2. Determine the center for cluster 2. From the remaining observations in the training dataset, pick an observation at random. Choose one that is different than the one you previously selected. This observation corresponds to a point that is far away from cluster center 1. Using the MNIST dataset as an example, you do the following:
    - For each of the remaining images, find the distance of the corresponding point from cluster center 1. Square the distance and assign a probability that is proportional to the square of the distance. That way, an image that is different from the one that you previously selected has a higher probability of getting selected as cluster center 2.
    - Choose one of the images randomly, based on probabilities assigned in the previous step. The point that corresponds to the image is cluster center 2.
  3. Repeat Step 2 to find cluster center 3. This time, find the distances of the remaining images from cluster center 2.
  4. Repeat the process until you have the  $K$  cluster centers.

To train a model in SageMaker, you create a training job. In the request, you provide configuration information by specifying the following `HyperParameters` string maps:

- To specify the number of clusters to create, add the `k` string.
- For greater accuracy, add the optional `extra_center_factor` string.
- To specify the strategy that you want to use to determine the initial cluster centers, add the `init_method` string and set its value to `random` or `k-means++`.

For more information about the SageMaker k-means estimator, see [K-means in the Amazon SageMaker Python SDK documentation](#).

You now have an initial set of cluster centers.

## Step 2: Iterate over the Training Dataset and Calculate Cluster Centers

The cluster centers that you created in the preceding step are mostly random, with some consideration for the training dataset. In this step, you use the training dataset to move these centers toward the true cluster centers. The algorithm iterates over the training dataset, and recalculates the  $K$  cluster centers.

1. Read a mini-batch of observations (a small, randomly chosen subset of all records) from the training dataset and do the following.

### Note

When creating a model training job, you specify the batch size in the `mini_batch_size` string in the `HyperParameters` string map.

- a. Assign all of the observations in the mini-batch to one of the clusters with the closest cluster center.
- b. Calculate the number of observations assigned to each cluster. Then, calculate the proportion of new points assigned per cluster.

For example, consider the following clusters:

Cluster c1 = 100 previously assigned points. You added 25 points from the mini-batch in this step.

Cluster c2 = 150 previously assigned points. You added 40 points from the mini-batch in this step.

Cluster c3 = 450 previously assigned points. You added 5 points from the mini-batch in this step.

Calculate the proportion of new points assigned to each of clusters as follows:

```
p1 = proportion of points assigned to c1 = 25/(100+25)
p2 = proportion of points assigned to c2 = 40/(150+40)
p3 = proportion of points assigned to c3 = 5/(450+5)
```

- c. Compute the center of the new points added to each cluster:

```
d1 = center of the new points added to cluster 1
d2 = center of the new points added to cluster 2
d3 = center of the new points added to cluster 3
```

- d. Compute the weighted average to find the updated cluster centers as follows:

```
Center of cluster 1 = ((1 - p1) * center of cluster 1) + (p1 * d1)
Center of cluster 2 = ((1 - p2) * center of cluster 2) + (p2 * d2)
Center of cluster 3 = ((1 - p3) * center of cluster 3) + (p3 * d3)
```

2. Read the next mini-batch, and repeat Step 1 to recalculate the cluster centers.
3. For more information about mini-batch k-means, see [Web-Scale k-means Clustering](#).

### Step 3: Reduce the Clusters from K to k

If the algorithm created  $K$  clusters—( $K = k*x$ ) where  $x$  is greater than 1—then it reduces the  $K$  clusters to  $k$  clusters. (For more information, see `extra_center_factor` in the preceding discussion.) It does this by applying Lloyd's method with `kmeans++` initialization to the  $K$  cluster centers. For more information about Lloyd's method, see [k-means clustering](#).

### K-Means Hyperparameters

In the `CreateTrainingJob` request, you specify the training algorithm that you want to use. You can also specify algorithm-specific hyperparameters as string-to-string maps. The following table lists the hyperparameters for the k-means training algorithm provided by Amazon SageMaker. For more information about how k-means clustering works, see [How K-Means Clustering Works \(p. 1421\)](#).

Parameter Name	Description
<code>feature_dim</code>	The number of features in the input data. <b>Required</b>

Parameter Name	Description
	Valid values: Positive integer
<b>k</b>	<p>The number of required clusters.</p> <p><b>Required</b></p> <p>Valid values: Positive integer</p>
<b>epochs</b>	<p>The number of passes done over the training data.</p> <p><b>Optional</b></p> <p>Valid values: Positive integer</p> <p>Default value: 1</p>
<b>eval_metrics</b>	<p>A JSON list of metric types used to report a score for the model. Allowed values are <code>msd</code> for Means Square Error and <code>ssd</code> for Sum of Square Distance. If test data is provided, the score is reported for each of the metrics requested.</p> <p><b>Optional</b></p> <p>Valid values: Either <code>[ \"msd\" ]</code> or <code>[ \"ssd\" ]</code> or <code>[ \"msd\", \"ssd\" ]</code>.</p> <p>Default value: <code>[ \"msd\" ]</code></p>
<b>extra_center_factor</b>	<p>The algorithm creates K centers = <code>num_clusters * extra_center_factor</code> as it runs and reduces the number of centers from K to <code>k</code> when finalizing the model.</p> <p><b>Optional</b></p> <p>Valid values: Either a positive integer or <code>auto</code>.</p> <p>Default value: <code>auto</code></p>
<b>half_life_time_size</b>	<p>Used to determine the weight given to an observation when computing a cluster mean. This weight decays exponentially as more points are observed. When a point is first observed, it is assigned a weight of 1 when computing the cluster mean. The decay constant for the exponential decay function is chosen so that after observing <code>half_life_time_size</code> points, its weight is 1/2. If set to 0, there is no decay.</p> <p><b>Optional</b></p> <p>Valid values: Non-negative integer</p> <p>Default value: 0</p>

Parameter Name	Description
<code>init_method</code>	<p>Method by which the algorithm chooses the initial cluster centers. The standard k-means approach chooses them at random. An alternative k-means++ method chooses the first cluster center at random. Then it spreads out the position of the remaining initial clusters by weighting the selection of centers with a probability distribution that is proportional to the square of the distance of the remaining data points from existing centers.</p> <p><b>Optional</b></p> <p>Valid values: Either <code>random</code> or <code>kmeans++</code>.</p> <p>Default value: <code>random</code></p>
<code>local_lloyd_init_method</code>	<p>The initialization method for Lloyd's expectation-maximization (EM) procedure used to build the final model containing <code>k</code> centers.</p> <p><b>Optional</b></p> <p>Valid values: Either <code>random</code> or <code>kmeans++</code>.</p> <p>Default value: <code>kmeans++</code></p>
<code>local_lloyd_max_iter</code>	<p>The maximum number of iterations for Lloyd's expectation-maximization (EM) procedure used to build the final model containing <code>k</code> centers.</p> <p><b>Optional</b></p> <p>Valid values: Positive integer</p> <p>Default value: 300</p>
<code>local_lloyd_num_trials</code>	<p>The number of times the Lloyd's expectation-maximization (EM) procedure with the least loss is run when building the final model containing <code>k</code> centers.</p> <p><b>Optional</b></p> <p>Valid values: Either a positive integer or <code>auto</code>.</p> <p>Default value: <code>auto</code></p>
<code>local_lloyd_tol</code>	<p>The tolerance for change in loss for early stopping of Lloyd's expectation-maximization (EM) procedure used to build the final model containing <code>k</code> centers.</p> <p><b>Optional</b></p> <p>Valid values: Float. Range in [0, 1].</p> <p>Default value: 0.0001</p>

Parameter Name	Description
mini_batch_size	<p>The number of observations per mini-batch for the data iterator.</p> <p><b>Optional</b></p> <p>Valid values: Positive integer</p> <p>Default value: 5000</p>

## Tune a K-Means Model

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

The Amazon SageMaker k-means algorithm is an unsupervised algorithm that groups data into clusters whose members are as similar as possible. Because it is unsupervised, it doesn't use a validation dataset that hyperparameters can optimize against. But it does take a test dataset and emits metrics that depend on the squared distance between the data points and the final cluster centroids at the end of each training run. To find the model that reports the tightest clusters on the test dataset, you can use a hyperparameter tuning job. The clusters optimize the similarity of their members.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker \(p. 1745\)](#).

### Metrics Computed by the K-Means Algorithm

The k-means algorithm computes the following metrics during training. When tuning a model, choose one of these metrics as the objective metric.

Metric Name	Description	Optimization Direction
test:msd	Mean squared distances between each record in the test set and the closest center of the model.	Minimize
test:ssd	Sum of the squared distances between each record in the test set and the closest center of the model.	Minimize

### Tunable K-Means Hyperparameters

Tune the Amazon SageMaker k-means model with the following hyperparameters. The hyperparameters that have the greatest impact on k-means objective metrics are: `mini_batch_size`, `extra_center_factor`, and `init_method`. Tuning the hyperparameter `epochs` generally results in minor improvements.

Parameter Name	Parameter Type	Recommended Ranges
epochs	IntegerParameterRanges	MinValue: 1, MaxValue:10

Parameter Name	Parameter Type	Recommended Ranges
extra_center_factor	IntegerParameterRanges	MinValue: 4, MaxValue:10
init_method	CategoricalParameterRanges	['kmeans++', 'random']
mini_batch_size	IntegerParameterRanges	MinValue: 3000, MaxValue:15000

## K-Means Response Formats

All SageMaker built-in algorithms adhere to the common input inference format described in [Common Data Formats - Inference](#). This topic contains a list of the available output formats for the SageMaker k-means algorithm.

### JSON Response Format

```
{
  "predictions": [
    {
      "closest_cluster": 1.0,
      "distance_to_cluster": 3.0,
    },
    {
      "closest_cluster": 2.0,
      "distance_to_cluster": 5.0,
    },
    ....
  ]
}
```

### JSONLINES Response Format

```
{"closest_cluster": 1.0, "distance_to_cluster": 3.0}
{"closest_cluster": 2.0, "distance_to_cluster": 5.0}
```

### RECORDIO Response Format

```
[
  Record = {
    features = {},
    label = {
      'closest_cluster': {
        keys: [],
        values: [1.0, 2.0] # float32
      },
      'distance_to_cluster': {
        keys: [],
        values: [3.0, 5.0] # float32
      },
    }
  }
]
```

### CSV Response Format

The first value in each line corresponds to `closest_cluster`.

The second value in each line corresponds to `distance_to_cluster`.

```
1.0,3.0  
2.0,5.0
```

## K-Nearest Neighbors (k-NN) Algorithm

Amazon SageMaker k-nearest neighbors (k-NN) algorithm is an index-based algorithm. It uses a non-parametric method for classification or regression. For classification problems, the algorithm queries the  $k$  points that are closest to the sample point and returns the most frequently used label of their class as the predicted label. For regression problems, the algorithm queries the  $k$  closest points to the sample point and returns the average of their feature values as the predicted value.

Training with the k-NN algorithm has three steps: sampling, dimension reduction, and index building. Sampling reduces the size of the initial dataset so that it fits into memory. For dimension reduction, the algorithm decreases the feature dimension of the data to reduce the footprint of the k-NN model in memory and inference latency. We provide two methods of dimension reduction methods: random projection and the fast Johnson-Lindenstrauss transform. Typically, you use dimension reduction for high-dimensional ( $d > 1000$ ) datasets to avoid the “curse of dimensionality” that troubles the statistical analysis of data that becomes sparse as dimensionality increases. The main objective of k-NN’s training is to construct the index. The index enables efficient lookups of distances between points whose values or class labels have not yet been determined and the  $k$  nearest points to use for inference.

## Input/Output Interface for the k-NN Algorithm

SageMaker k-NN supports train and test data channels.

- Use a *train channel* for data that you want to sample and construct into the k-NN index.
- Use a *test channel* to emit scores in log files. Scores are listed as one line per mini-batch: accuracy for classifier, mean-squared error (mse) for regressor for score.

For training inputs, k-NN supports `text/csv` and `application/x-recordio-protobuf` data formats. For input type `text/csv`, the first `label_size` columns are interpreted as the label vector for that row. You can use either File mode or Pipe mode to train models on data that is formatted as `recordIO-wrapped-protobuf` or as `CSV`.

For inference inputs, k-NN supports the `application/json`, `application/x-recordio-protobuf`, and `text/csv` data formats. The `text/csv` format accepts a `label_size` and `encoding` parameter. It assumes a `label_size` of 0 and a UTF-8 encoding.

For inference outputs, k-NN supports the `application/json` and `application/x-recordio-protobuf` data formats. These two data formats also support a verbose output mode. In verbose output mode, the API provides the search results with the distances vector sorted from smallest to largest, and corresponding elements in the labels vector.

For batch transform, k-NN supports the application/jsonlines data format for both input and output. An example input is as follows:

```
content-type: application/jsonlines

{"features": [1.5, 16.0, 14.0, 23.0]}
{"data": {"features": {"values": [1.5, 16.0, 14.0, 23.0]}}}
```

An example output is as follows:

```
accept: application/jsonlines

{"predicted_label": 0.0}
{"predicted_label": 2.0}
```

For more information on input and output file formats, see [Data Formats for k-NN Training Input \(p. 1433\)](#) for training, [k-NN Request and Response Formats \(p. 1434\)](#) for inference, and the [k-NN Sample Notebooks \(p. 1429\)](#).

## k-NN Sample Notebooks

For a sample notebook that uses the SageMaker k-nearest neighbor algorithm to predict wilderness cover types from geological and forest service data, see the [K-Nearest Neighbor Covertype](#).

Use a Jupyter notebook instance to run the example in SageMaker. To learn how to create and open a Jupyter notebook instance in SageMaker, see [Use Amazon SageMaker Notebook Instances \(p. 120\)](#). Once you have created a notebook instance and opened it, select the **SageMaker Examples** tab to see a list of all the SageMaker example notebooks. Find K-Nearest Neighbor notebooks in the **Introduction to Amazon algorithms** section. To open a notebook, click on its **Use** tab and select **Create copy**.

## How the k-NN Algorithm Works

### Step 1: Sample

To specify the total number of data points to be sampled from the training dataset, use the `sample_size` parameter. For example, if the initial dataset has 1,000 data points and the `sample_size` is set to 100, where the total number of instances is 2, each worker would sample 50 points. A total set of 100 data points would be collected. Sampling runs in linear time with respect to the number of data points.

### Step 2: Perform Dimension Reduction

The current implementation of the k-NN algorithm has two methods of dimension reduction. You specify the method in the `dimension_reduction_type` hyperparameter. The `sign` method specifies a random projection, which uses a linear projection using a matrix of random signs, and the `fjlt` method specifies a fast Johnson-Lindenstrauss transform, a method based on the Fourier transform. Both methods preserve the L2 and inner product distances. The `fjlt` method should be used when the target dimension is large and has better performance with CPU inference. The methods differ in their computational complexity. The `sign` method requires  $O(ndk)$  time to reduce the dimension of a batch of  $n$  points of dimension  $d$  into a target dimension  $k$ . The `fjlt` method requires  $O(nd \log(d))$  time, but the constants involved are larger. Using dimension reduction introduces noise into the data and this noise can reduce prediction accuracy.

### Step 3: Build an Index

During inference, the algorithm queries the index for the k-nearest-neighbors of a sample point. Based on the references to the points, the algorithm makes the classification or regression prediction. It makes the prediction based on the class labels or values provided. k-NN provides three different types of indexes: a flat index, an inverted index, and an inverted index with product quantization. You specify the type with the `index_type` parameter.

## Serialize the Model

When the k-NN algorithm finishes training, it serializes three files to prepare for inference.

- `model_algo-1`: Contains the serialized index for computing the nearest neighbors.
- `model_algo-1.labels`: Contains serialized labels (np.float32 binary format) for computing the predicted label based on the query result from the index.
- `model_algo-1.json`: Contains the JSON-formatted model metadata which stores the `k` and `predictor_type` hyper-parameters from training for inference along with other relevant state.

With the current implementation of k-NN, you can modify the metadata file to change the way predictions are computed. For example, you can change `k` to 10 or change `predictor_type` to `regressor`.

```
{
  "k": 5,
  "predictor_type": "classifier",
  "dimension_reduction": {"type": "sign", "seed": 3, "target_dim": 10, "input_dim": 20},
  "normalize": False,
  "version": "1.0"
}
```

## EC2 Instance Recommendation for the k-NN Algorithm

### Instance Recommendation for Training with the k-NN Algorithm

To start, try running training on a CPU, using, for example, an `ml.m5.2xlarge` instance, or on a GPU using, for example, an `ml.p2.xlarge` instance.

### Instance Recommendation for Inference with the k-NN Algorithm

Inference requests from CPUs generally have a lower average latency than requests from GPUs because there is a tax on CPU-to-GPU communication when you use GPU hardware. However, GPUs generally have higher throughput for larger batches.

## k-NN Hyperparameters

Parameter Name	Description
<code>feature_dim</code>	The number of features in the input data. <b>Required</b> Valid values: positive integer.
<code>k</code>	The number of nearest neighbors. <b>Required</b> Valid values: positive integer
<code>predictor_type</code>	The type of inference to use on the data labels. <b>Required</b> Valid values: <code>classifier</code> for classification or <code>regressor</code> for regression.
<code>sample_size</code>	The number of data points to be sampled from the training data set.

Parameter Name	Description
	<p><b>Required</b></p> <p>Valid values: positive integer</p>
dimension_reduction_target	<p>The target dimension to reduce to.</p> <p><b>Required</b> when you specify the dimension_reduction_type parameter.</p> <p>Valid values: positive integer greater than 0 and less than feature_dim.</p>
dimension_reduction_type	<p>The type of dimension reduction method.</p> <p><b>Optional</b></p> <p>Valid values: <i>sign</i> for random projection or <i>fjlt</i> for the fast Johnson-Lindenstrauss transform.</p> <p>Default value: No dimension reduction</p>
faiss_index_ivf_nlists	<p>The number of centroids to construct in the index when index_type is <i>faiss.IVFFlat</i> or <i>faiss.IVFPQ</i>.</p> <p><b>Optional</b></p> <p>Valid values: positive integer</p> <p>Default value: <i>auto</i>, which resolves to <code>sqrt(sample_size)</code>.</p>
faiss_index_pq_m	<p>The number of vector sub-components to construct in the index when index_type is set to <i>faiss.IVFPQ</i>.</p> <p>The FaceBook AI Similarity Search (FAISS) library requires that the value of faiss_index_pq_m is a divisor of the data dimension. If faiss_index_pq_m is not a divisor of the data dimension, we increase the data dimension to smallest integer divisible by faiss_index_pq_m. If no dimension reduction is applied, the algorithm adds a padding of zeros. If dimension reduction is applied, the algorithm increase the value of the dimension_reduction_target hyper-parameter.</p> <p><b>Optional</b></p> <p>Valid values: One of the following positive integers: 1, 2, 3, 4, 8, 12, 16, 20, 24, 28, 32, 40, 48, 56, 64, 96</p>
index_metric	<p>The metric to measure the distance between points when finding nearest neighbors. When training with index_type set to <i>faiss.IVFPQ</i>, the INNER_PRODUCT distance and COSINE similarity are not supported.</p> <p><b>Optional</b></p> <p>Valid values: <i>L2</i> for Euclidean-distance, <i>INNER_PRODUCT</i> for inner-product distance, <i>COSINE</i> for cosine similarity.</p> <p>Default value: <i>L2</i></p>

Parameter Name	Description
index_type	<p>The type of index.</p> <p><b>Optional</b></p> <p>Valid values: <i>faiss.Flat</i>, <i>faiss.IVFFlat</i>, <i>faiss.IVFPQ</i>.</p> <p>Default values: <i>faiss.Flat</i></p>
mini_batch_size	<p>The number of observations per mini-batch for the data iterator.</p> <p><b>Optional</b></p> <p>Valid values: positive integer</p> <p>Default value: 5000</p>

## Tune a k-NN Model

The Amazon SageMaker k-nearest neighbors algorithm is a supervised algorithm. The algorithm consumes a test data set and emits a metric about the accuracy for a classification task or about the mean squared error for a regression task. These accuracy metrics compare the model predictions for their respective task to the ground truth provided by the empirical test data. To find the best model that reports the highest accuracy or lowest error on the test dataset, run a hyperparameter tuning job for k-NN.

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric appropriate for the prediction task of the algorithm. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric. The hyperparameters are used only to help estimate model parameters and are not used by the trained model to make predictions.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker \(p. 1745\)](#).

### Metrics Computed by the k-NN Algorithm

The k-nearest neighbors algorithm computes one of two metrics in the following table during training depending on the type of task specified by the `predictor_type` hyper-parameter.

- *classifier* specifies a classification task and computes `test:accuracy`
- *regressor* specifies a regression task and computes `test:mse`.

Choose the `predictor_type` value appropriate for the type of task undertaken to calculate the relevant objective metric when tuning a model.

Metric Name	Description	Optimization Direction
<code>test:accuracy</code>	When <code>predictor_type</code> is set to <i>classifier</i> , k-NN compares the predicted label, based on the average of the k-nearest neighbors' labels, to the ground truth label provided in the test channel data. The accuracy reported ranges from 0.0 (0%) to 1.0 (100%).	Maximize

Metric Name	Description	Optimization Direction
test:mse	When <code>predictor_type</code> is set to <code>regressor</code> , k-NN compares the predicted label, based on the average of the k-nearest neighbors' labels, to the ground truth label provided in the test channel data. The mean squared error is computed by comparing the two labels.	Minimize

## Tunable k-NN Hyperparameters

Tune the Amazon SageMaker k-nearest neighbor model with the following hyperparameters.

Parameter Name	Parameter Type	Recommended Ranges
k	IntegerParameterRanges	MinValue: 1, MaxValue: 1024
sample_size	IntegerParameterRanges	MinValue: 256, MaxValue: 20000000

## Data Formats for k-NN Training Input

All Amazon SageMaker built-in algorithms adhere to the common input training formats described in [Common Data Formats - Training](#). This topic contains a list of the available input formats for the SageMaker k-nearest-neighbor algorithm.

### CSV Data Format

`content-type: text/csv; label_size=1`

```
4,1.2,1.3,9.6,20.3
```

The first `label_size` columns are interpreted as the label vector for that row.

### RECORDIO Data Format

`content-type: application/x-recordio-protobuf`

```
[  
    Record = {  
        features = {  
            'values': {  
                values: [1.2, 1.3, 9.6, 20.3]  # float32  
            }  
        },  
        label = {  
            'values': {  
                values: [4]  # float32  
            }  
        }  
    }  
]
```

## k-NN Request and Response Formats

All Amazon SageMaker built-in algorithms adhere to the common input inference format described in [Common Data Formats - Inference](#). This topic contains a list of the available output formats for the SageMaker k-nearest-neighbor algorithm.

### INPUT: CSV Request Format

content-type: text/csv

```
1.2,1.3,9.6,20.3
```

This accepts a `label_size` or `encoding` parameter. It assumes a `label_size` of 0 and a utf-8 encoding.

### INPUT: JSON Request Format

content-type: application/json

```
{
  "instances": [
    {"data": {"features": {"values": [-3, -1, -4, 2]}},
     {"features": [3.0, 0.1, 0.04, 0.002]}}
  ]
}
```

### INPUT: JSONLINES Request Format

content-type: application/jsonlines

```
{"features": [1.5, 16.0, 14.0, 23.0]}
{"data": {"features": {"values": [1.5, 16.0, 14.0, 23.0]}}}
```

### INPUT: RECORDIO Request Format

content-type: application/x-recordio-protobuf

```
[
  Record = {
    features = {
      'values': {
        values: [-3, -1, -4, 2] # float32
      }
    },
    label = {}
  },
  Record = {
    features = {
      'values': {
        values: [3.0, 0.1, 0.04, 0.002] # float32
      }
    },
    label = {}
  },
]
```

### OUTPUT: JSON Response Format

accept: application/json

```
{
  "predictions": [
```

```

        {"predicted_label": 0.0},
        {"predicted_label": 2.0}
    ]
}
```

### OUTPUT: JSONLINES Response Format

accept: application/jsonlines

```
{"predicted_label": 0.0}
{"predicted_label": 2.0}
```

### OUTPUT: VERBOSE JSON Response Format

In verbose mode, the API provides the search results with the distances vector sorted from smallest to largest, with corresponding elements in the labels vector. In this example, k is set to 3.

accept: application/json; verbose=true

```
{
  "predictions": [
    {
      "predicted_label": 0.0,
      "distances": [3.11792408, 3.89746071, 6.32548437],
      "labels": [0.0, 1.0, 0.0]
    },
    {
      "predicted_label": 2.0,
      "distances": [1.08470316, 3.04917915, 5.25393973],
      "labels": [2.0, 2.0, 0.0]
    }
  ]
}
```

### OUTPUT: RECORDIO-PROTOBUF Response Format

content-type: application/x-recordio-protobuf

```
[
  Record = {
    features = {},
    label = {
      'predicted_label': {
        values: [0.0] # float32
      }
    }
  },
  Record = {
    features = {},
    label = {
      'predicted_label': {
        values: [2.0] # float32
      }
    }
  }
]
```

### OUTPUT: VERBOSE RECORDIO-PROTOBUF Response Format

In verbose mode, the API provides the search results with the distances vector sorted from smallest to largest, with corresponding elements in the labels vector. In this example, k is set to 3.

accept: application/x-recordio-protobuf; verbose=true

```
[  
    Record = {  
        features = {},  
        label = {  
            'predicted_label': {  
                values: [0.0] # float32  
            },  
            'distances': {  
                values: [3.11792408, 3.89746071, 6.32548437] # float32  
            },  
            'labels': {  
                values: [0.0, 1.0, 0.0] # float32  
            }  
        }  
    },  
    Record = {  
        features = {},  
        label = {  
            'predicted_label': {  
                values: [0.0] # float32  
            },  
            'distances': {  
                values: [1.08470316, 3.04917915, 5.25393973] # float32  
            },  
            'labels': {  
                values: [2.0, 2.0, 0.0] # float32  
            }  
        }  
    }  
]
```

### SAMPLE OUTPUT for the k-NN Algorithm

For regressor tasks:

```
[06/08/2018 20:15:33 INFO 140026520049408] #test_score (algo-1) : ('mse',  
0.01333333333333334)
```

For classifier tasks:

```
[06/08/2018 20:15:46 INFO 140285487171328] #test_score (algo-1) : ('accuracy',  
0.9866666666666669)
```

## Latent Dirichlet Allocation (LDA) Algorithm

The Amazon SageMaker Latent Dirichlet Allocation (LDA) algorithm is an unsupervised learning algorithm that attempts to describe a set of observations as a mixture of distinct categories. LDA is most commonly used to discover a user-specified number of topics shared by documents within a text corpus. Here each observation is a document, the features are the presence (or occurrence count) of each word, and the categories are the topics. Since the method is unsupervised, the topics are not specified up front, and are not guaranteed to align with how a human may naturally categorize documents. The topics are learned as a probability distribution over the words that occur in each document. Each document, in turn, is described as a mixture of topics.

The exact content of two documents with similar topic mixtures will not be the same. But overall, you would expect these documents to more frequently use a shared subset of words, than when compared with a document from a different topic mixture. This allows LDA to discover these word groups and use

them to form topics. As an extremely simple example, given a set of documents where the only words that occur within them are: *eat*, *sleep*, *play*, *meow*, and *bark*, LDA might produce topics like the following:

<b>Topic</b>	<b><i>eat</i></b>	<b><i>sleep</i></b>	<b><i>play</i></b>	<b><i>meow</i></b>	<b><i>bark</i></b>
Topic 1	0.1	0.3	0.2	0.4	0.0
Topic 2	0.2	0.1	0.4	0.0	0.3

You can infer that documents that are more likely to fall into Topic 1 are about cats (who are more likely to *meow* and *sleep*), and documents that fall into Topic 2 are about dogs (who prefer to *play* and *bark*). These topics can be found even though the words dog and cat never appear in any of the texts.

## Choosing between Latent Dirichlet Allocation (LDA) and Neural Topic Model (NTM)

Topic models are commonly used to produce topics from corpuses that (1) coherently encapsulate semantic meaning and (2) describe documents well. As such, topic models aim to minimize perplexity and maximize topic coherence.

Perplexity is an intrinsic language modeling evaluation metric that measures the inverse of the geometric mean per-word likelihood in your test data. A lower perplexity score indicates better generalization performance. Research has shown that the likelihood computed per word often does not align to human judgement, and can be entirely non-correlated, thus topic coherence has been introduced. Each inferred topic from your model consists of words, and topic coherence is computed to the top N words for that particular topic from your model. It is often defined as the average or median of the pairwise word-similarity scores of the words in that topic e.g., Pointwise Mutual Information (PMI). A promising model generates coherent topics or topics with high topic coherence scores.

While the objective is to train a topic model that minimizes perplexity and maximizes topic coherence, there is often a tradeoff with both LDA and NTM. Recent research by Amazon, Dinget et al., 2018 has shown that NTM is promising for achieving high topic coherence but LDA trained with collapsed Gibbs sampling achieves better perplexity. There is a tradeoff between perplexity and topic coherence. From a practicality standpoint regarding hardware and compute power, SageMaker NTM hardware is more flexible than LDA and can scale better because NTM can run on CPU and GPU and can be parallelized across multiple GPU instances, whereas LDA only supports single-instance CPU training.

## Input/Output Interface for the LDA Algorithm

LDA expects data to be provided on the train channel, and optionally supports a test channel, which is scored by the final model. LDA supports both `recordIO-wrapped-protobuf` (dense and sparse) and CSV file formats. For CSV, the data must be dense and have dimension equal to *number of records* \* *vocabulary size*. LDA can be trained in File or Pipe mode when using recordIO-wrapped protobuf, but only in File mode for the CSV format.

For inference, `text/csv`, `application/json`, and `application/x-recordio-protobuf` content types are supported. Sparse data can also be passed for `application/json` and `application/x-recordio-protobuf`. LDA inference returns `application/json` or `application/x-recordio-protobuf` *predictions*, which include the `topic_mixture` vector for each observation.

Please see the [LDA Sample Notebooks \(p. 1438\)](#) for more detail on training and inference formats.

## EC2 Instance Recommendation for the LDA Algorithm

LDA currently only supports single-instance CPU training. CPU instances are recommended for hosting/inference.

## LDA Sample Notebooks

For a sample notebook that shows how to train the SageMaker Latent Dirichlet Allocation algorithm on a dataset and then how to deploy the trained model to perform inferences about the topic mixtures in input documents, see the [An Introduction to SageMaker LDA](#). For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see [Use Amazon SageMaker Notebook Instances \(p. 120\)](#). Once you have created a notebook instance and opened it, select the **SageMaker Examples** tab to see a list of all the SageMaker samples. The topic modeling example notebooks using the NTM algorithms are located in the **Introduction to Amazon algorithms** section. To open a notebook, click on its **Use** tab and select **Create copy**.

## How LDA Works

Amazon SageMaker LDA is an unsupervised learning algorithm that attempts to describe a set of observations as a mixture of different categories. These categories are themselves a probability distribution over the features. LDA is a generative probability model, which means it attempts to provide a model for the distribution of outputs and inputs based on latent variables. This is opposed to discriminative models, which attempt to learn how inputs map to outputs.

You can use LDA for a variety of tasks, from clustering customers based on product purchases to automatic harmonic analysis in music. However, it is most commonly associated with topic modeling in text corpuses. Observations are referred to as documents. The feature set is referred to as vocabulary. A feature is referred to as a word. And the resulting categories are referred to as topics.

### Note

Lemmatization significantly increases algorithm performance and accuracy. Consider pre-processing any input text data.

An LDA model is defined by two parameters:

- $\alpha$ —A prior estimate on topic probability (in other words, the average frequency that each topic within a given document occurs).
- $\beta$ —a collection of  $k$  topics where each topic is given a probability distribution over the vocabulary used in a document corpus, also called a "topic-word distribution."

LDA is a "bag-of-words" model, which means that the order of words does not matter. LDA is a generative model where each document is generated word-by-word by choosing a topic mixture  $\theta \sim \text{Dirichlet}(\alpha)$ .

For each word in the document:

- Choose a topic  $z \sim \text{Multinomial}(\theta)$
- Choose the corresponding topic-word distribution  $\beta_z$ .
- Draw a word  $w \sim \text{Multinomial}(\beta_z)$ .

When training the model, the goal is to find parameters  $\alpha$  and  $\beta$ , which maximize the probability that the text corpus is generated by the model.

The most popular methods for estimating the LDA model use Gibbs sampling or Expectation Maximization (EM) techniques. The Amazon SageMaker LDA uses tensor spectral decomposition. This provides several advantages:

- **Theoretical guarantees on results.** The standard EM-method is guaranteed to converge only to local optima, which are often of poor quality.
- **Embarrassingly parallelizable.** The work can be trivially divided over input documents in both training and inference. The EM-method and Gibbs Sampling approaches can be parallelized, but not as easily.
- **Fast.** Although the EM-method has low iteration cost it is prone to slow convergence rates. Gibbs Sampling is also subject to slow convergence rates and also requires a large number of samples.

At a high-level, the tensor decomposition algorithm follows this process:

1. The goal is to calculate the spectral decomposition of a  $V \times V \times V$  tensor, which summarizes the moments of the documents in our corpus.  $V$  is vocabulary size (in other words, the number of distinct words in all of the documents). The spectral components of this tensor are the LDA parameters  $\alpha$  and  $\beta$ , which maximize the overall likelihood of the document corpus. However, because vocabulary size tends to be large, this  $V \times V \times V$  tensor is prohibitively large to store in memory.
2. Instead, it uses a  $V \times V$  moment matrix, which is the two-dimensional analog of the tensor from step 1, to find a whitening matrix of dimension  $V \times k$ . This matrix can be used to convert the  $V \times V$  moment matrix into a  $k \times k$  identity matrix.  $k$  is the number of topics in the model.
3. This same whitening matrix can then be used to find a smaller  $k \times k \times k$  tensor. When spectrally decomposed, this tensor has components that have a simple relationship with the components of the  $V \times V \times V$  tensor.
4. *Alternating Least Squares* is used to decompose the smaller  $k \times k \times k$  tensor. This provides a substantial improvement in memory consumption and speed. The parameters  $\alpha$  and  $\beta$  can be found by “unwhitening” these outputs in the spectral decomposition.

After the LDA model's parameters have been found, you can find the topic mixtures for each document. You use stochastic gradient descent to maximize the likelihood function of observing a given topic mixture corresponding to these data.

Topic quality can be improved by increasing the number of topics to look for in training and then filtering out poor quality ones. This is in fact done automatically in SageMaker LDA: 25% more topics are computed and only the ones with largest associated Dirichlet priors are returned. To perform further topic filtering and analysis, you can increase the topic count and modify the resulting LDA model as follows:

```
> import mxnet as mx
> alpha, beta = mx.nd.array.load('model.tar.gz')
> # modify alpha and beta
> mx.nd.save('new_model.tar.gz', [new_alpha, new_beta])
> # upload to S3 and create new SageMaker model using the console
```

## LDA Hyperparameters

In the `CreateTrainingJob` request, you specify the training algorithm. You can also specify algorithm-specific hyperparameters as string-to-string maps. The following table lists the hyperparameters for the LDA training algorithm provided by Amazon SageMaker. For more information, see [How LDA Works \(p. 1438\)](#).

Parameter Name	Description
<code>num_topics</code>	<p>The number of topics for LDA to find within the data.</p> <p><b>Required</b></p> <p>Valid values: positive integer</p>
<code>feature_dim</code>	<p>The size of the vocabulary of the input document corpus.</p> <p><b>Required</b></p> <p>Valid values: positive integer</p>
<code>mini_batch_size</code>	<p>The total number of documents in the input document corpus.</p> <p><b>Required</b></p> <p>Valid values: positive integer</p>
<code>alpha0</code>	<p>Initial guess for the concentration parameter: the sum of the elements of the Dirichlet prior. Small values are more likely to generate sparse topic mixtures and large values (greater than 1.0) produce more uniform mixtures.</p> <p><b>Optional</b></p> <p>Valid values: Positive float</p> <p>Default value: 1.0</p>
<code>max_restarts</code>	<p>The number of restarts to perform during the Alternating Least Squares (ALS) spectral decomposition phase of the algorithm. Can be used to find better quality local minima at the expense of additional computation, but typically should not be adjusted.</p> <p><b>Optional</b></p> <p>Valid values: Positive integer</p> <p>Default value: 10</p>

Parameter Name	Description
<code>max_iterations</code>	<p>The maximum number of iterations to perform during the ALS phase of the algorithm. Can be used to find better quality minima at the expense of additional computation, but typically should not be adjusted.</p> <p><b>Optional</b></p> <p>Valid values: Positive integer</p> <p>Default value: 1000</p>
<code>tol</code>	<p>Target error tolerance for the ALS phase of the algorithm. Can be used to find better quality minima at the expense of additional computation, but typically should not be adjusted.</p> <p><b>Optional</b></p> <p>Valid values: Positive float</p> <p>Default value: 1e-8</p>

## Tune an LDA Model

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

LDA is an unsupervised topic modeling algorithm that attempts to describe a set of observations (documents) as a mixture of different categories (topics). The “per-word log-likelihood” (PWLL) metric measures the likelihood that a learned set of topics (an LDA model) accurately describes a test document dataset. Larger values of PWLL indicate that the test data is more likely to be described by the LDA model.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker \(p. 1745\)](#).

### Metrics Computed by the LDA Algorithm

The LDA algorithm reports on a single metric during training: `test:pwll`. When tuning a model, choose this metric as the objective metric.

Metric Name	Description	Optimization Direction
<code>test:pwll</code>	Per-word log-likelihood on the test dataset. The likelihood that the test dataset is accurately described by the learned LDA model.	Maximize

### Tunable LDA Hyperparameters

You can tune the following hyperparameters for the LDA algorithm. Both hyperparameters, `alpha0` and `num_topics`, can affect the LDA objective metric (`test:pwll`). If you don't already know the optimal

values for these hyperparameters, which maximize per-word log-likelihood and produce an accurate LDA model, automatic model tuning can help find them.

Parameter Name	Parameter Type	Recommended Ranges
alpha0	ContinuousParameterRanges	MinValue: 0.1, MaxValue: 10
num_topics	IntegerParameterRanges	MinValue: 1, MaxValue: 150

## Linear Learner Algorithm

*Linear models* are supervised learning algorithms used for solving either classification or regression problems. For input, you give the model labeled examples  $(x, y)$ .  $x$  is a high-dimensional vector and  $y$  is a numeric label. For binary classification problems, the label must be either 0 or 1. For multiclass classification problems, the labels must be from 0 to `num_classes` - 1. For regression problems,  $y$  is a real number. The algorithm learns a linear function, or, for classification problems, a linear threshold function, and maps a vector  $x$  to an approximation of the label  $y$ .

The Amazon SageMaker linear learner algorithm provides a solution for both classification and regression problems. With the SageMaker algorithm, you can simultaneously explore different training objectives and choose the best solution from a validation set. You can also explore a large number of models and choose the best. The best model optimizes either of the following:

- Continuous objectives, such as mean square error, cross entropy loss, absolute error.
- Discrete objectives suited for classification, such as F1 measure, precision, recall, or accuracy.

Compared with methods that provide a solution for only continuous objectives, the SageMaker linear learner algorithm provides a significant increase in speed over naive hyperparameter optimization techniques. It is also more convenient.

The linear learner algorithm requires a data matrix, with rows representing the observations, and columns representing the dimensions of the features. It also requires an additional column that contains the labels that match the data points. At a minimum, Amazon SageMaker linear learner requires you to specify input and output data locations, and objective type (classification or regression) as arguments. The feature dimension is also required. For more information, see [CreateTrainingJob](#). You can specify additional parameters in the `HyperParameters` string map of the request body. These parameters control the optimization procedure, or specifics of the objective function that you train on. For example, the number of epochs, regularization, and loss type.

If you're using [Managed Spot Training](#), the linear learner algorithm supports using [checkpoints to take a snapshot of the state of the model](#).

### Topics

- [Tune a linear learner model \(p. 1454\)](#)
- [Linear learner response formats \(p. 1456\)](#)

## Input/Output interface for the linear learner algorithm

The Amazon SageMaker linear learner algorithm supports three data channels: train, validation (optional), and test (optional). If you provide validation data, the `S3DataDistributionType` should be `FullyReplicated`. The algorithm logs validation loss at every epoch, and uses a sample of the validation data to calibrate and select the best model. If you don't provide validation data, the algorithm uses a sample of the training data to calibrate and select the model. If you provide test data, the algorithm logs include the test score for the final model.

**For training**, the linear learner algorithm supports both `recordIO-wrapped protobuf` and `csv` formats. For the `application/x-recordio-protobuf` input type, only `Float32` tensors are supported. For the `text/csv` input type, the first column is assumed to be the label, which is the target variable for prediction. You can use either File mode or Pipe mode to train linear learner models on data that is formatted as `recordIO-wrapped-protobuf` or as `CSV`.

**For inference**, the linear learner algorithm supports the `application/json`, `application/x-recordio-protobuf`, and `text/csv` formats. When you make predictions on new data, the format of the response depends on the type of model. **For regression** (`predictor_type='regressor'`), the `score` is the prediction produced by the model. **For classification** (`predictor_type='binary_classifier'` or `predictor_type='multiclass_classifier'`), the model returns a `score` and also a `predicted_label`. The `predicted_label` is the class predicted by the model and the `score` measures the strength of that prediction.

- **For binary classification**, `predicted_label` is 0 or 1, and `score` is a single floating point number that indicates how strongly the algorithm believes that the label should be 1.
- **For multiclass classification**, the `predicted_class` will be an integer from 0 to `num_classes-1`, and `score` will be a list of one floating point number per class.

To interpret the `score` in classification problems, you have to consider the loss function used. If the `loss` hyperparameter value is `logistic` for binary classification or `softmax_loss` for multiclass classification, then the `score` can be interpreted as the probability of the corresponding class. These are the loss values used by the linear learner when the `loss` value is `auto` default value. But if the `loss` is set to `hinge_loss`, then the `score` cannot be interpreted as a probability. This is because hinge loss corresponds to a Support Vector Classifier, which does not produce probability estimates.

For more information on input and output file formats, see [Linear learner response formats \(p. 1456\)](#). For more information on inference formats, and the [Linear learner sample notebooks \(p. 1443\)](#).

## EC2 instance recommendation for the linear learner algorithm

You can train the linear learner algorithm on single- or multi-machine CPU and GPU instances. During testing, we have not found substantial evidence that multi-GPU computers are faster than single-GPU computers. Results can vary, depending on your specific use case.

## Linear learner sample notebooks

The following table outlines a variety of sample notebooks that address different use cases of Amazon SageMaker linear learner algorithm.

Notebook Title	Description
<a href="#">An Introduction with the MNIST dataset</a>	Using the MNIST dataset, we train a binary classifier to predict a single digit.
<a href="#">Predict Breast Cancer</a>	Using UCI's Breast Cancer dataset, we train a model to predict Breast Cancer.

Notebook Title	Description
<a href="#">How to Build a Multiclass Classifier?</a>	Using UCI's Covertype dataset, we demonstrate how to train a multiclass classifier.
<a href="#">How to Build a Machine Learning (ML) Pipeline for Inference?</a>	Using a Scikit-learn container, we demonstrate how to build an end-to-end ML pipeline.

For instructions on how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see [Use Amazon SageMaker Notebook Instances \(p. 120\)](#). After you have created a notebook instance and opened it, choose the **SageMaker Examples** tab to see a list of all of the SageMaker samples. The topic modeling example notebooks using the linear learning algorithm are located in the **Introduction to Amazon algorithms** section. To open a notebook, choose its **Use** tab and choose **Create copy**.

## How linear learner works

There are three steps involved in the implementation of the linear learner algorithm: preprocess, train, and validate. Step 4 provides example code that shows how to deploy a trained model.

### Step 1: Preprocess

Normalization, or feature scaling, is an important preprocessing step for certain loss functions that ensures the model being trained on a dataset does not become dominated by the weight of a single feature. The Amazon SageMaker Linear Learner algorithm has a normalization option to assist with this preprocessing step. If normalization is turned on, the algorithm first goes over a small sample of the data to learn the mean value and standard deviation for each feature and for the label. Each of the features in the full dataset is then shifted to have mean of zero and scaled to have a unit standard deviation.

#### Note

For best results, ensure your data is shuffled before training. Training with unshuffled data may cause training to fail.

You can configure whether the linear learner algorithm normalizes the feature data and the labels using the `normalize_data` and `normalize_label` hyperparameters, respectively. Normalization is enabled by default for both features and labels for regression. Only the features can be normalized for binary classification and this is the default behavior.

### Step 2: Train

With the linear learner algorithm, you train with a distributed implementation of stochastic gradient descent (SGD). You can control the optimization process by choosing the optimization algorithm. For example, you can choose to use Adam, AdaGrad, stochastic gradient descent, or other optimization algorithms. You also specify their hyperparameters, such as momentum, learning rate, and the learning rate schedule. If you aren't sure which algorithm or hyperparameter value to use, choose a default that works for the majority of datasets.

During training, you simultaneously optimize multiple models, each with slightly different objectives. For example, you vary L1 or L2 regularization and try out different optimizer settings.

### Step 3: Validate and set the threshold

When training multiple models in parallel, the models are evaluated against a validation set to select the most optimal model once training is complete. For regression, the most optimal model is the one that achieves the best loss on the validation set. For classification, a sample of the validation set is used to calibrate the classification threshold. The most optimal model selected is the one that achieves the best binary classification selection criteria on the validation set. Examples of such criteria include the F1 measure, accuracy, and cross-entropy loss.

### Note

If the algorithm is not provided a validation set, then evaluating and selecting the most optimal model is not possible. To take advantage of parallel training and model selection ensure you provide a validation set to the algorithm.

### Step 4: Deploy a trained linear model

Here is an example of Python code that you can use to deploy a model in MXNet that has been trained with SageMaker linear learner

```
import mxnet as mx
import tarfile
t = tarfile.open('model.tar.gz', 'r:gz')
t.extractall()

# Load the mxnet module from the model files
mod = mx.module.Module.load('mx-mod', 0)
# model's weights
mod._arg_params['fc0_weight'].asnumpy().flatten()

# model bias
mod._arg_params['fc0_bias'].asnumpy().flatten()
mod.bind(data_shapes=data_iter.provide_data) #data_iter is an iterator configured with your test data
#perform inference
result = mod.predict(data_iter)
```

### Linear learner hyperparameters

The following table contains the hyperparameters for the linear learner algorithm. These are parameters that are set by users to facilitate the estimation of model parameters from data. The required hyperparameters that must be set are listed first, in alphabetical order. The optional hyperparameters that can be set are listed next, also in alphabetical order. When a hyperparameter is set to auto, Amazon SageMaker will automatically calculate and set the value of that hyperparameter.

Parameter Name	Description
<code>num_classes</code>	<p>The number of classes for the response variable. The algorithm assumes that classes are labeled 0, ..., <code>num_classes</code> - 1.</p> <p><b>Required</b> when <code>predictor_type</code> is <code>multiclass_classifier</code>. Otherwise, the algorithm ignores it.</p> <p>Valid values: Integers from 3 to 1,000,000</p>
<code>predictor_type</code>	<p>Specifies the type of target variable as a binary classification, multiclass classification, or regression.</p> <p><b>Required</b></p> <p>Valid values: <code>binary_classifier</code>, <code>multiclass_classifier</code>, or <code>regressor</code></p>
<code>accuracy_top_k</code>	<p>When computing the top-k accuracy metric for multiclass classification, the value of <code>k</code>. If the model assigns one of the top-k scores to the true label, an example is scored as correct.</p> <p><b>Optional</b></p> <p>Valid values: Positive integers</p>

Parameter Name	Description
	Default value: 3
balance_multiclass_weight	<p>Specifies whether to use class weights, which give each class equal importance in the loss function. Used only when the predictor_type is multiclass_classifier.</p> <p><b>Optional</b></p> <p>Valid values: true, false</p> <p>Default value: false</p>
beta_1	<p>The exponential decay rate for first-moment estimates. Applies only when the optimizer value is adam.</p> <p><b>Optional</b></p> <p>Valid values: auto or floating-point value between 0 and 1.0</p> <p>Default value: auto</p>
beta_2	<p>The exponential decay rate for second-moment estimates. Applies only when the optimizer value is adam.</p> <p><b>Optional</b></p> <p>Valid values: auto or floating-point integer between 0 and 1.0</p> <p>Default value: auto</p>
bias_lr_mult	<p>Allows a different learning rate for the bias term. The actual learning rate for the bias is learning_rate * bias_lr_mult.</p> <p><b>Optional</b></p> <p>Valid values: auto or positive floating-point integer</p> <p>Default value: auto</p>
bias_wd_mult	<p>Allows different regularization for the bias term. The actual L2 regularization weight for the bias is wd * bias_wd_mult. By default, there is no regularization on the bias term.</p> <p><b>Optional</b></p> <p>Valid values: auto or non-negative floating-point integer</p> <p>Default value: auto</p>

Parameter Name	Description
binary_classifier_model_selection_criteria	<p>When <code>prediction_type</code> is set to <code>binary_classifier</code>, the model evaluation criteria for the validation dataset (or for the training dataset if you don't provide a validation dataset). Criteria include:</p> <ul style="list-style-type: none"> <li>• <code>accuracy</code>—The model with the highest accuracy.</li> <li>• <code>f_beta</code>—The model with the highest F1 score. The default is <code>F1</code>.</li> <li>• <code>precision_at_target_recall</code>—The model with the highest precision at a given recall target.</li> <li>• <code>recall_at_target_precision</code>—The model with the highest recall at a given precision target.</li> <li>• <code>loss_function</code>—The model with the lowest value of the loss function used in training.</li> </ul> <p><b>Optional</b></p> <p>Valid values: <code>accuracy</code>, <code>f_beta</code>, <code>precision_at_target_recall</code>, <code>recall_at_target_precision</code>, or <code>loss_function</code></p> <p>Default value: <code>accuracy</code></p>
early_stopping_patience	<p>If no improvement is made in the relevant metric, the number of epochs to wait before ending training. If you have provided a value for <code>binary_classifier_model_selection_criteria</code>, the metric is that value. Otherwise, the metric is the same as the value specified for the <code>loss</code> hyperparameter.</p> <p>The metric is evaluated on the validation data. If you haven't provided validation data, the metric is always the same as the value specified for the <code>loss</code> hyperparameter and is evaluated on the training data. To disable early stopping, set <code>early_stopping_patience</code> to a value greater than the value specified for <code>epochs</code>.</p> <p><b>Optional</b></p> <p>Valid values: Positive integer</p> <p>Default value: 3</p>
early_stopping_tolerance	<p>The relative tolerance to measure an improvement in loss. If the ratio of the improvement in loss divided by the previous best loss is smaller than this value, early stopping considers the improvement to be zero.</p> <p><b>Optional</b></p> <p>Valid values: Positive floating-point integer</p> <p>Default value: 0.001</p>
epochs	<p>The maximum number of passes over the training data.</p> <p><b>Optional</b></p> <p>Valid values: Positive integer</p> <p>Default value: 15</p>

Parameter Name	Description
<code>f_beta</code>	<p>The value of beta to use when calculating F score metrics for binary or multiclass classification. Also used if the value specified for <code>binary_classifier_model_selection_criteria</code> is <code>f_beta</code>.</p> <p><b>Optional</b></p> <p>Valid values: Positive floating-point integers</p> <p>Default value: 1.0</p>
<code>feature_dim</code>	<p>The number of features in the input data.</p> <p><b>Optional</b></p> <p>Valid values: <code>auto</code> or positive integer</p> <p>Default values: <code>auto</code></p>
<code>huber_delta</code>	<p>The parameter for Huber loss. During training and metric evaluation, compute L2 loss for errors smaller than delta and L1 loss for errors larger than delta.</p> <p><b>Optional</b></p> <p>Valid values: Positive floating-point integer</p> <p>Default value: 1.0</p>
<code>init_bias</code>	<p>Initial weight for the bias term.</p> <p><b>Optional</b></p> <p>Valid values: Floating-point integer</p> <p>Default value: 0</p>
<code>init_method</code>	<p>Sets the initial distribution function used for model weights. Functions include:</p> <ul style="list-style-type: none"> <li>• <code>uniform</code>—Uniformly distributed between (-scale, +scale)</li> <li>• <code>normal</code>—Normal distribution, with mean 0 and sigma</li> </ul> <p><b>Optional</b></p> <p>Valid values: <code>uniform</code> or <code>normal</code></p> <p>Default value: <code>uniform</code></p>
<code>init_scale</code>	<p>Scales an initial uniform distribution for model weights. Applies only when the <code>init_method</code> hyperparameter is set to <code>uniform</code>.</p> <p><b>Optional</b></p> <p>Valid values: Positive floating-point integer</p> <p>Default value: 0.07</p>

Parameter Name	Description
<code>init_sigma</code>	<p>The initial standard deviation for the normal distribution. Applies only when the <code>init_method</code> hyperparameter is set to <code>normal</code>.</p> <p><b>Optional</b></p> <p>Valid values: Positive floating-point integer</p> <p>Default value: 0.01</p>
<code>l1</code>	<p>The L1 regularization parameter. If you don't want to use L1 regularization, set the value to 0.</p> <p><b>Optional</b></p> <p>Valid values: <code>auto</code> or non-negative float</p> <p>Default value: <code>auto</code></p>
<code>learning_rate</code>	<p>The step size used by the optimizer for parameter updates.</p> <p><b>Optional</b></p> <p>Valid values: <code>auto</code> or positive floating-point integer</p> <p>Default value: <code>auto</code>, whose value depends on the optimizer chosen.</p>
<code>loss</code>	<p>Specifies the loss function.</p> <p>The available loss functions and their default values depend on the value of <code>predictor_type</code>:</p> <ul style="list-style-type: none"> <li>If the <code>predictor_type</code> is set to <code>regressor</code>, the available options are <code>auto</code>, <code>squared_loss</code>, <code>absolute_loss</code>, <code>eps_insensitive_squared_loss</code>, <code>eps_insensitive_absolute_loss</code>, <code>quantile_loss</code>, and <code>huber_loss</code>. The default value for <code>auto</code> is <code>squared_loss</code>.</li> <li>If the <code>predictor_type</code> is set to <code>binary_classifier</code>, the available options are <code>auto</code>, <code>logistic</code>, and <code>hinge_loss</code>. The default value for <code>auto</code> is <code>logistic</code>.</li> <li>If the <code>predictor_type</code> is set to <code>multiclass_classifier</code>, the available options are <code>auto</code> and <code>softmax_loss</code>. The default value for <code>auto</code> is <code>softmax_loss</code>.</li> </ul> <p>Valid values: <code>auto</code>, <code>logistic</code>, <code>squared_loss</code>, <code>absolute_loss</code>, <code>hinge_loss</code>, <code>eps_insensitive_squared_loss</code>, <code>eps_insensitive_absolute_loss</code>, <code>quantile_loss</code>, or <code>huber_loss</code></p> <p><b>Optional</b></p> <p>Default value: <code>auto</code></p>

Parameter Name	Description
loss_insensitivity	<p>The parameter for the epsilon-insensitive loss type. During training and metric evaluation, any error smaller than this value is considered to be zero.</p> <p><b>Optional</b></p> <p>Valid values: Positive floating-point integer</p> <p>Default value: 0.01</p>
lr_scheduler_factor	<p>For every <code>lr_scheduler_step</code> hyperparameter, the learning rate decreases by this quantity. Applies only when the <code>use_lr_scheduler</code> hyperparameter is set to <code>true</code>.</p> <p><b>Optional</b></p> <p>Valid values: <code>auto</code> or positive floating-point integer between 0 and 1</p> <p>Default value: <code>auto</code></p>
lr_scheduler_minimum_lr	<p>The learning rate never decreases to a value lower than the value set for <code>lr_scheduler_minimum_lr</code>. Applies only when the <code>use_lr_scheduler</code> hyperparameter is set to <code>true</code>.</p> <p><b>Optional</b></p> <p>Valid values: <code>auto</code> or positive floating-point integer</p> <p>Default value: <code>auto</code></p>
lr_scheduler_step	<p>The number of steps between decreases of the learning rate. Applies only when the <code>use_lr_scheduler</code> hyperparameter is set to <code>true</code>.</p> <p><b>Optional</b></p> <p>Valid values: <code>auto</code> or positive integer</p> <p>Default value: <code>auto</code></p>
margin	<p>The margin for the <code>hinge_loss</code> function.</p> <p><b>Optional</b></p> <p>Valid values: Positive floating-point integer</p> <p>Default value: 1.0</p>
mini_batch_size	<p>The number of observations per mini-batch for the data iterator.</p> <p><b>Optional</b></p> <p>Valid values: Positive integer</p> <p>Default value: 1000</p>

Parameter Name	Description
momentum	<p>The momentum of the sgd optimizer.</p> <p><b>Optional</b></p> <p>Valid values: <code>auto</code> or a floating-point integer between 0 and 1.0</p> <p>Default value: <code>auto</code></p>
normalize_data	<p>Normalizes the feature data before training. Data normalization shifts the data for each feature to have a mean of zero and scales it to have unit standard deviation.</p> <p><b>Optional</b></p> <p>Valid values: <code>auto</code>, <code>true</code>, or <code>false</code></p> <p>Default value: <code>true</code></p>
normalize_label	<p>Normalizes the label. Label normalization shifts the label to have a mean of zero and scales it to have unit standard deviation.</p> <p>The <code>auto</code> default value normalizes the label for regression problems but does not for classification problems. If you set the <code>normalize_label</code> hyperparameter to <code>true</code> for classification problems, the algorithm ignores it.</p> <p><b>Optional</b></p> <p>Valid values: <code>auto</code>, <code>true</code>, or <code>false</code></p> <p>Default value: <code>auto</code></p>
num_calibration_samples	<p>The number of observations from the validation dataset to use for model calibration (when finding the best threshold).</p> <p><b>Optional</b></p> <p>Valid values: <code>auto</code> or positive integer</p> <p>Default value: <code>auto</code></p>
num_models	<p>The number of models to train in parallel. For the default, <code>auto</code>, the algorithm decides the number of parallel models to train. One model is trained according to the given training parameter (regularization, optimizer, loss), and the rest by close parameters.</p> <p><b>Optional</b></p> <p>Valid values: <code>auto</code> or positive integer</p> <p>Default values: <code>auto</code></p>

Parameter Name	Description
num_point_for_scaler	<p>The number of data points to use for calculating normalization or unbiaseding of terms.</p> <p><b>Optional</b></p> <p>Valid values: Positive integer</p> <p>Default value: 10,000</p>
optimizer	<p>The optimization algorithm to use.</p> <p><b>Optional</b></p> <p>Valid values:</p> <ul style="list-style-type: none"> <li>• <code>auto</code>—The default value.</li> <li>• <code>sgd</code>—Stochastic gradient descent.</li> <li>• <code>adam</code>—<a href="#">Adaptive momentum estimation</a>.</li> <li>• <code>rmsprop</code>—A gradient-based optimization technique that uses a moving average of squared gradients to normalize the gradient.</li> </ul> <p>Default value: <code>auto</code>. The default setting for <code>auto</code> is <code>adam</code>.</p>
positive_example_weight	<p>The weight assigned to positive examples when training a binary classifier. The weight of negative examples is fixed at 1. If you want the algorithm to choose a weight so that errors in classifying negative vs. positive examples have equal impact on training loss, specify <code>balanced</code>. If you want the algorithm to choose the weight that optimizes performance, specify <code>auto</code>.</p> <p><b>Optional</b></p> <p>Valid values: <code>balanced</code>, <code>auto</code>, or a positive floating-point integer</p> <p>Default value: 1.0</p>
quantile	<p>The quantile for quantile loss. For quantile <math>q</math>, the model attempts to produce predictions so that the value of <code>true_label</code> is greater than the prediction with probability <math>q</math>.</p> <p><b>Optional</b></p> <p>Valid values: Floating-point integer between 0 and 1</p> <p>Default value: 0.5</p>
target_precision	<p>The target precision. If <code>binary_classifier_model_selection_criteria</code> is <code>recall_at_target_precision</code>, then precision is held at this value while recall is maximized.</p> <p><b>Optional</b></p> <p>Valid values: Floating-point integer between 0 and 1.0</p> <p>Default value: 0.8</p>

Parameter Name	Description
target_recall	<p>The target recall. If <code>binary_classifier_model_selection_criteria</code> is <code>precision_at_target_recall</code>, then recall is held at this value while precision is maximized.</p> <p><b>Optional</b></p> <p>Valid values: Floating-point integer between 0 and 1.0</p> <p>Default value: 0.8</p>
unbias_data	<p>Unbiases the features before training so that the mean is 0. By default data is unbiased as the <code>use_bias</code> hyperparameter is set to <code>true</code>.</p> <p><b>Optional</b></p> <p>Valid values: <code>auto</code>, <code>true</code>, or <code>false</code></p> <p>Default value: <code>auto</code></p>
unbias_label	<p>Unbiases labels before training so that the mean is 0. Applies to regression only if the <code>use_bias</code> hyperparameter is set to <code>true</code>.</p> <p><b>Optional</b></p> <p>Valid values: <code>auto</code>, <code>true</code>, or <code>false</code></p> <p>Default value: <code>auto</code></p>
use_bias	<p>Specifies whether the model should include a bias term, which is the intercept term in the linear equation.</p> <p><b>Optional</b></p> <p>Valid values: <code>true</code> or <code>false</code></p> <p>Default value: <code>true</code></p>
use_lr_scheduler	<p>Whether to use a scheduler for the learning rate. If you want to use a scheduler, specify <code>true</code>.</p> <p><b>Optional</b></p> <p>Valid values: <code>true</code> or <code>false</code></p> <p>Default value: <code>true</code></p>
wd	<p>The weight decay parameter, also known as the L2 regularization parameter. If you don't want to use L2 regularization, set the value to 0.</p> <p><b>Optional</b></p> <p>Valid values: <code>auto</code> or non-negative floating-point integer</p> <p>Default value: <code>auto</code></p>

## Tune a linear learner model

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

The linear learner algorithm also has an internal mechanism for tuning hyperparameters separate from the automatic model tuning feature described here. By default, the linear learner algorithm tunes hyperparameters by training multiple models in parallel. When you use automatic model tuning, the linear learner internal tuning mechanism is turned off automatically. This sets the number of parallel models, `num_models`, to 1. The algorithm ignores any value that you set for `num_models`.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker \(p. 1745\)](#).

### Metrics computed by the linear learner algorithm

The linear learner algorithm reports the metrics in the following table, which are computed during training. Choose one of them as the objective metric. To avoid overfitting, we recommend tuning the model against a validation metric instead of a training metric.

Metric Name	Description	Optimization Direction
<code>test:objective_loss</code>	The mean value of the objective loss function on the test dataset after the model is trained. By default, the loss is logistic loss for binary classification and squared loss for regression. To set the loss to other types, use the <code>loss</code> hyperparameter.	Minimize
<code>test:binary_classifier_accuracy</code>	The accuracy of the final model on the test dataset.	Maximize
<code>test:binary_f_beta</code>	The F_beta score of the final model on the test dataset. By default, it is the F1 score, which is the harmonic mean of precision and recall.	Maximize
<code>test:precision</code>	The precision of the final model on the test dataset. If you choose this metric as the objective, we recommend setting a target recall by setting the <code>binary_classifier_model_selection</code> hyperparameter to <code>precision_at_target_recall</code> and setting the value for the <code>target_recall</code> hyperparameter.	Maximize
<code>test:recall</code>	The recall of the final model on the test dataset. If you choose this metric as the objective, we recommend setting a target precision by setting the <code>binary_classifier_model_selection</code> hyperparameter to <code>recall_at_target_precision</code> and setting the value for the <code>target_precision</code> hyperparameter.	Maximize
<code>validation:objective_loss</code>	The mean value of the objective loss function on the validation dataset every epoch. By default,	Minimize

Metric Name	Description	Optimization Direction
	the loss is logistic loss for binary classification and squared loss for regression. To set loss to other types, use the <code>loss</code> hyperparameter.	
<code>validation:binary_accuracy</code>	The accuracy of the final model on the validation dataset.	Maximize
<code>validation:binary_f1</code>	The F_beta score of the final model on the validation dataset. By default, the F_beta score is the F1 score, which is the harmonic mean of the <code>validation:precision</code> and <code>validation:recall</code> metrics.	Maximize
<code>validation:precision</code>	The precision of the final model on the validation dataset. If you choose this metric as the objective, we recommend setting a target recall by setting the <code>binary_classifier_model_selection</code> hyperparameter to <code>precision_at_target_recall</code> and setting the value for the <code>target_recall</code> hyperparameter.	Maximize
<code>validation:recall</code>	The recall of the final model on the validation dataset. If you choose this metric as the objective, we recommend setting a target precision by setting the <code>binary_classifier_model_selection</code> hyperparameter to <code>recall_at_target_precision</code> and setting the value for the <code>target_precision</code> hyperparameter.	Maximize

## Tuning linear learner hyperparameters

You can tune a linear learner model with the following hyperparameters.

Parameter Name	Parameter Type	Recommended Ranges
<code>wd</code>	<code>ContinuousParameterRanges</code>	<code>MinValue: 1e-7, MaxValue: 1</code>
<code>l1</code>	<code>ContinuousParameterRanges</code>	<code>MinValue: 1e-7, MaxValue: 1</code>
<code>learning_rate</code>	<code>ContinuousParameterRanges</code>	<code>MinValue: 1e-5, MaxValue: 1</code>
<code>mini_batch_size</code>	<code>IntegerParameterRanges</code>	<code>MinValue: 100, MaxValue: 5000</code>
<code>use_bias</code>	<code>CategoricalParameterRanges</code>	<code>[True, False]</code>
<code>positive_example_weight</code>	<code>ContinuousParameterRanges</code>	<code>MinValue: 1e-5, MaxValue: 1e5</code>

## Linear learner response formats

### JSON response formats

All Amazon SageMaker built-in algorithms adhere to the common input inference format described in [Common Data Formats - Inference](#). The following are the available output formats for the SageMaker linear learner algorithm.

#### Binary Classification

```
let response = {
  "predictions": [
    {
      "score": 0.4,
      "predicted_label": 0
    }
  ]
}
```

#### Multiclass Classification

```
let response = {
  "predictions": [
    {
      "score": [0.1, 0.2, 0.4, 0.3],
      "predicted_label": 2
    }
  ]
}
```

#### Regression

```
let response = {
  "predictions": [
    {
      "score": 0.4
    }
  ]
}
```

## JSONLINES response formats

### Binary Classification

```
{"score": 0.4, "predicted_label": 0}
```

### Multiclass Classification

```
{"score": [0.1, 0.2, 0.4, 0.3], "predicted_label": 2}
```

### Regression

```
{"score": 0.4}
```

## RECORDIO response formats

### Binary Classification

```
[  
    Record = {  
        features = {},  
        label = {  
            'score': {  
                keys: [],  
                values: [0.4] # float32  
            },  
            'predicted_label': {  
                keys: [],  
                values: [0.0] # float32  
            }  
        }  
    }  
]
```

### Multiclass Classification

```
[  
    Record = {  
        "features": [],  
        "label": {  
            "score": {  
                "values": [0.1, 0.2, 0.3, 0.4]  
            },  
            "predicted_label": {  
                "values": [3]  
            }  
        },  
        "uid": "abc123",  
        "metadata": "{created_at: '2017-06-03'}"  
    }  
]
```

### Regression

```
[  
    Record = {  
        features = {},  
        label = {  
            'score': {  
                keys: [],  
                values: [0.4] # float32  
            }  
        }  
    }  
]
```

## Neural Topic Model (NTM) Algorithm

Amazon SageMaker NTM is an unsupervised learning algorithm that is used to organize a corpus of documents into *topics* that contain word groupings based on their statistical distribution. Documents that contain frequent occurrences of words such as "bike", "car", "train", "mileage", and "speed" are likely to share a topic on "transportation" for example. Topic modeling can be used to classify or summarize documents based on the topics detected or to retrieve information or recommend content based on topic similarities. The topics from documents that NTM learns are characterized as a *latent representation* because the topics are inferred from the observed word distributions in the corpus. The semantics of topics are usually inferred by examining the top ranking words they contain. Because the method is unsupervised, only the number of topics, not the topics themselves, are prespecified. In addition, the topics are not guaranteed to align with how a human might naturally categorize documents.

Topic modeling provides a way to visualize the contents of a large document corpus in terms of the learned topics. Documents relevant to each topic might be indexed or searched for based on their soft topic labels. The latent representations of documents might also be used to find similar documents in the topic space. You can also use the latent representations of documents that the topic model learns for input to another supervised algorithm such as a document classifier. Because the latent representations of documents are expected to capture the semantics of the underlying documents, algorithms based in part on these representations are expected to perform better than those based on lexical features alone.

Although you can use both the Amazon SageMaker NTM and LDA algorithms for topic modeling, they are distinct algorithms and can be expected to produce different results on the same input data.

For more information on the mathematics behind NTM, see [Neural Variational Inference for Text Processing](#).

## Input/Output Interface for the NTM Algorithm

Amazon SageMaker Neural Topic Model supports four data channels: train, validation, test, and auxiliary. The validation, test, and auxiliary data channels are optional. If you specify any of these optional channels, set the value of the `S3DataDistributionType` parameter for them to `FullyReplicated`. If you provide validation data, the loss on this data is logged at every epoch, and the model stops training as soon as it detects that the validation loss is not improving. If you don't provide validation data, the algorithm stops early based on the training data, but this can be less efficient. If you provide test data, the algorithm reports the test loss from the final model.

The train, validation, and test data channels for NTM support both `recordIO-wrapped-protobuf` (dense and sparse) and `csv` file formats. For `csv` format, each row must be represented densely with zero counts for words not present in the corresponding document, and have dimension equal to:  $(\text{number of records}) * (\text{vocabulary size})$ . You can use either File mode or Pipe mode to train models on data that is formatted as `recordIO-wrapped-protobuf` or as `csv`. The auxiliary channel is used to supply a text file that contains vocabulary. By supplying the vocabulary file, users are able to see the top words for each of the topics printed in the log instead of their integer IDs. Having the vocabulary file also allows NTM to compute the Word Embedding Topic Coherence (WETC) scores, a new metric displayed in the log that captures similarity among the top words in each topic effectively. The `ContentType` for the auxiliary channel is `text/plain`, with each line containing a single word, in the order corresponding to the integer IDs provided in the data. The vocabulary file must be named `vocab.txt` and currently only UTF-8 encoding is supported.

For inference, `text/csv`, `application/json`, `application/jsonlines`, and `application/x-recordio-protobuf` content types are supported. Sparse data can also be passed for `application/json` and `application/x-recordio-protobuf`. NTM inference returns `application/json` or `application/x-recordio-protobuf` *predictions*, which include the `topic_weights` vector for each observation.

See the [blog post](#) and the companion [notebook](#) for more details on using the auxiliary channel and the WETC scores. For more information on how to compute the WETC score, see [Coherence-Aware Neural Topic Modeling](#). We used the pairwise WETC described in this paper for the Amazon SageMaker Neural Topic Model.

For more information on input and output file formats, see [NTM Response Formats \(p. 1462\)](#) for inference and the [NTM Sample Notebooks \(p. 1459\)](#).

## EC2 Instance Recommendation for the NTM Algorithm

NTM training supports both GPU and CPU instance types. We recommend GPU instances, but for certain workloads, CPU instances may result in lower training costs. CPU instances should be sufficient for inference.

## NTM Sample Notebooks

For a sample notebook that uses the SageMaker NTM algorithm to uncover topics in documents from a synthetic data source where the topic distributions are known, see the [Introduction to Basic Functionality of NTM](#). For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see [Use Amazon SageMaker Notebook Instances \(p. 120\)](#). Once you have created a notebook instance and opened it, select the **SageMaker Examples** tab to see a list of all the SageMaker samples. The topic modeling example notebooks using the NTM algorithms are located in the **Introduction to Amazon algorithms** section. To open a notebook, click on its **Use** tab and select **Create copy**.

## NTM Hyperparameters

Parameter Name	Description
<code>feature_dim</code>	The vocabulary size of the dataset. <b>Required</b> Valid values: Positive integer (min: 1, max: 1,000,000)
<code>num_topics</code>	The number of required topics. <b>Required</b> Valid values: Positive integer (min: 2, max: 1000)
<code>batch_norm</code>	Whether to use batch normalization during training. <b>Optional</b> Valid values: <i>true</i> or <i>false</i> Default value: <i>false</i>
<code>clip_gradient</code>	The maximum magnitude for each gradient component. <b>Optional</b> Valid values: Float (min: 1e-3) Default value: Infinity
<code>encoder_layers</code>	The number of layers in the encoder and the output size of each layer. When set to <i>auto</i> , the algorithm uses two layers of sizes 3 x <code>num_topics</code> and 2 x <code>num_topics</code> respectively. <b>Optional</b> Valid values: Comma-separated list of positive integers or <i>auto</i>

Parameter Name	Description
	Default value: <i>auto</i>
encoder_layers_activation	<p>The activation function to use in the encoder layers.</p> <p><b>Optional</b></p> <p>Valid values:</p> <ul style="list-style-type: none"> <li>• sigmoid: <a href="#">Sigmoid function</a></li> <li>• tanh: <a href="#">Hyperbolic tangent</a></li> <li>• relu: <a href="#">Rectified linear unit</a></li> </ul> <p>Default value: sigmoid</p>
epochs	<p>The maximum number of passes over the training data.</p> <p><b>Optional</b></p> <p>Valid values: Positive integer (min: 1)</p> <p>Default value: 50</p>
learning_rate	<p>The learning rate for the optimizer.</p> <p><b>Optional</b></p> <p>Valid values: Float (min: 1e-6, max: 1.0)</p> <p>Default value: 0.001</p>
mini_batch_size	<p>The number of examples in each mini batch.</p> <p><b>Optional</b></p> <p>Valid values: Positive integer (min: 1, max: 10000)</p> <p>Default value: 256</p>
num_patience_epochs	<p>The number of successive epochs over which early stopping criterion is evaluated. Early stopping is triggered when the change in the loss function drops below the specified tolerance within the last num_patience_epochs number of epochs. To disable early stopping, set num_patience_epochs to a value larger than epochs.</p> <p><b>Optional</b></p> <p>Valid values: Positive integer (min: 1)</p> <p>Default value: 3</p>

Parameter Name	Description
optimizer	<p>The optimizer to use for training.</p> <p><b>Optional</b></p> <p>Valid values:</p> <ul style="list-style-type: none"> <li>sgd: <a href="#">Stochastic gradient descent</a></li> <li>adam: <a href="#">Adaptive momentum estimation</a></li> <li>adagrad: <a href="#">Adaptive gradient algorithm</a></li> <li>adadelta: <a href="#">An adaptive learning rate algorithm</a></li> <li>rmsprop: <a href="#">Root mean square propagation</a></li> </ul> <p>Default value: adadelta</p>
rescale_gradient	<p>The rescale factor for gradient.</p> <p><b>Optional</b></p> <p>Valid values: float (min: 1e-3, max: 1.0)</p> <p>Default value: 1.0</p>
sub_sample	<p>The fraction of the training data to sample for training per epoch.</p> <p><b>Optional</b></p> <p>Valid values: Float (min: 0.0, max: 1.0)</p> <p>Default value: 1.0</p>
tolerance	<p>The maximum relative change in the loss function. Early stopping is triggered when change in the loss function drops below this value within the last num_patience_epochs number of epochs.</p> <p><b>Optional</b></p> <p>Valid values: Float (min: 1e-6, max: 0.1)</p> <p>Default value: 0.001</p>
weight_decay	<p>The weight decay coefficient. Adds L2 regularization.</p> <p><b>Optional</b></p> <p>Valid values: Float (min: 0.0, max: 1.0)</p> <p>Default value: 0.0</p>

## Tune an NTM Model

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

Amazon SageMaker NTM is an unsupervised learning algorithm that learns latent representations of large collections of discrete data, such as a corpus of documents. Latent representations use inferred variables that are not directly measured to model the observations in a dataset. Automatic model tuning on NTM helps you find the model that minimizes loss over the training or validation data. *Training loss* measures how well the model fits the training data. *Validation loss* measures how well the model can generalize to data that it is not trained on. Low training loss indicates that a model is a good fit to the training data. Low validation loss indicates that a model has not overfit the training data and so should be able to model documents successfully on which it has not been trained. Usually, it's preferable to have both losses be small. However, minimizing training loss too much might result in overfitting and increase validation loss, which would reduce the generality of the model.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker \(p. 1745\)](#).

### Metrics Computed by the NTM Algorithm

The NTM algorithm reports a single metric that is computed during training: `validation:total_loss`. The total loss is the sum of the reconstruction loss and Kullback-Leibler divergence. When tuning hyperparameter values, choose this metric as the objective.

Metric Name	Description	Optimization Direction
<code>validation:total_loss</code>	Total Loss on validation set	Minimize

### Tunable NTM Hyperparameters

You can tune the following hyperparameters for the NTM algorithm. Usually setting low `mini_batch_size` and small `learning_rate` values results in lower validation losses, although it might take longer to train. Low validation losses don't necessarily produce more coherent topics as interpreted by humans. The effect of other hyperparameters on training and validation loss can vary from dataset to dataset. To see which values are compatible, see [NTM Hyperparameters \(p. 1459\)](#).

Parameter Name	Parameter Type	Recommended Ranges
<code>encoder_layers_activation</code>	CategoricalParameterRanges	[ <code>'sigmoid'</code> , <code>'tanh'</code> , <code>'relu'</code> ]
<code>learning_rate</code>	ContinuousParameterRange	MinValue: <code>1e-4</code> , MaxValue: <code>0.1</code>
<code>mini_batch_size</code>	IntegerParameterRanges	MinValue: <code>16</code> , MaxValue: <code>2048</code>
<code>optimizer</code>	CategoricalParameterRanges	[ <code>'sgd'</code> , <code>'adam'</code> , <code>'adadelta'</code> ]
<code>rescale_gradient</code>	ContinuousParameterRange	MinValue: <code>0.1</code> , MaxValue: <code>1.0</code>
<code>weight_decay</code>	ContinuousParameterRange	MinValue: <code>0.0</code> , MaxValue: <code>1.0</code>

### NTM Response Formats

All Amazon SageMaker built-in algorithms adhere to the common input inference format described in [Common Data Formats - Inference](#). This topic contains a list of the available output formats for the SageMaker NTM algorithm.

## JSON Response Format

```
{  
    "predictions": [  
        {"topic_weights": [0.02, 0.1, 0,...]},  
        {"topic_weights": [0.25, 0.067, 0,...]}  
    ]  
}
```

## JSONLINES Response Format

```
{"topic_weights": [0.02, 0.1, 0,...]}  
{"topic_weights": [0.25, 0.067, 0,...]}
```

## RECORDIO Response Format

```
[  
    Record = {  
        features = {},  
        label = {  
            'topic_weights': {  
                keys: [],  
                values: [0.25, 0.067, 0, ...] # float32  
            }  
        }  
    },  
    Record = {  
        features = {},  
        label = {  
            'topic_weights': {  
                keys: [],  
                values: [0.25, 0.067, 0, ...] # float32  
            }  
        }  
    }  
]
```

## Object2Vec Algorithm

The Amazon SageMaker Object2Vec algorithm is a general-purpose neural embedding algorithm that is highly customizable. It can learn low-dimensional dense embeddings of high-dimensional objects. The embeddings are learned in a way that preserves the semantics of the relationship between pairs of objects in the original space in the embedding space. You can use the learned embeddings to efficiently compute nearest neighbors of objects and to visualize natural clusters of related objects in low-dimensional space, for example. You can also use the embeddings as features of the corresponding objects in downstream supervised tasks, such as classification or regression.

Object2Vec generalizes the well-known Word2Vec embedding technique for words that is optimized in the SageMaker [BlazingText algorithm \(p. 1364\)](#). For a blog post that discusses how to apply Object2Vec to some practical use cases, see [Introduction to Amazon SageMaker Object2Vec](#).

## I/O Interface for the Object2Vec Algorithm

You can use Object2Vec on many input data types, including the following examples.

Input Data Type	Example
Sentence-sentence pairs	"A soccer game with multiple males playing." and "Some men are playing a sport."
Labels-sequence pairs	The genre tags of the movie "Titanic", such as "Romance" and "Drama", and its short description: "James Cameron's Titanic is an epic, action-packed romance set against the ill-fated maiden voyage of the R.M.S. Titanic. She was the most luxurious liner of her era, a ship of dreams, which ultimately carried over 1,500 people to their death in the ice cold waters of the North Atlantic in the early hours of April 15, 1912."
Customer-customer pairs	The customer ID of Jane and customer ID of Jackie.
Product-product pairs	The product ID of football and product ID of basketball.
Item review user-item pairs	A user's ID and the items she has bought, such as apple, pear, and orange.

To transform the input data into the supported formats, you must preprocess it. Currently, Object2Vec natively supports two types of input:

- A discrete token, which is represented as a list of a single `integer-id`. For example, `[10]`.
- A sequences of discrete tokens, which is represented as a list of `integer-ids`. For example, `[0, 12, 10, 13]`.

The object in each pair can be asymmetric. For example, the pairs can be (token, sequence) or (token, token) or (sequence, sequence). For token inputs, the algorithm supports simple embeddings as compatible encoders. For sequences of token vectors, the algorithm supports the following as encoders:

- Average-pooled embeddings
- Hierarchical convolutional neural networks (CNNs),
- Multi-layered bidirectional long short-term memory (BiLSTMs)

The input label for each pair can be one of the following:

- A categorical label that expresses the relationship between the objects in the pair
- A score that expresses the strength of the similarity between the two objects

For categorical labels used in classification, the algorithm supports the cross-entropy loss function. For ratings/score-based labels used in regression, the algorithm supports the mean squared error (MSE) loss

function. Specify these loss functions with the `output_layer` hyperparameter when you create the model training job.

## EC2 Instance Recommendation for the Object2Vec Algorithm

The type of Amazon Elastic Compute Cloud (Amazon EC2) instance that you use depends on whether you are training or running inferences.

### Instance Recommendation for Training

When training a model using the Object2Vec algorithm on a CPU, start with an `ml.m5.2xlarge` instance. For training on a GPU, start with an `ml.p2.xlarge` instance. If the training takes too long on this instance, you can use a larger instance, such as an `ml.m5.4xlarge` or an `ml.m5.12xlarge` instance. Currently, the Object2Vec algorithm can train only on a single machine. However, it does offer support for multiple GPUs.

### Instance Recommendation for Inference

For inference with a trained Object2Vec model that has a deep neural network, we recommend using `ml.p3.2xlarge` GPU instance. Due to GPU memory scarcity, the `INFERENCE_PREFERRED_MODE` environment variable can be specified to optimize on whether the [the section called "GPU optimization: Classification or Regression" \(p. 1477\)](#) or [the section called "GPU optimization: Encoder Embeddings" \(p. 1478\)](#) inference network is loaded into GPU.

## Object2Vec Sample Notebooks

- [Using Object2Vec to Encode Sentences into Fixed Length Embeddings](#)
- [Using Object2Vec to learn document embeddings](#)

### Note

To run the notebooks on a notebook instance, see [Example Notebooks \(p. 131\)](#). To run the notebooks on Studio, see [Create or Open an Amazon SageMaker Studio Notebook \(p. 79\)](#).

## How Object2Vec Works

When using the Amazon SageMaker Object2Vec algorithm, you follow the standard workflow: process the data, train the model, and produce inferences.

### Topics

- [Step 1: Process Data \(p. 1465\)](#)
- [Step 2: Train a Model \(p. 1465\)](#)
- [Step 3: Produce Inferences \(p. 1466\)](#)

### Step 1: Process Data

During preprocessing, convert the data to the [JSON Lines](#) text file format specified in [Data Formats for Object2Vec Training \(p. 1477\)](#). To get the highest accuracy during training, also randomly shuffle the data before feeding it into the model. How you generate random permutations depends on the language. For python, you could use `np.random.shuffle`; for Unix, `shuf`.

### Step 2: Train a Model

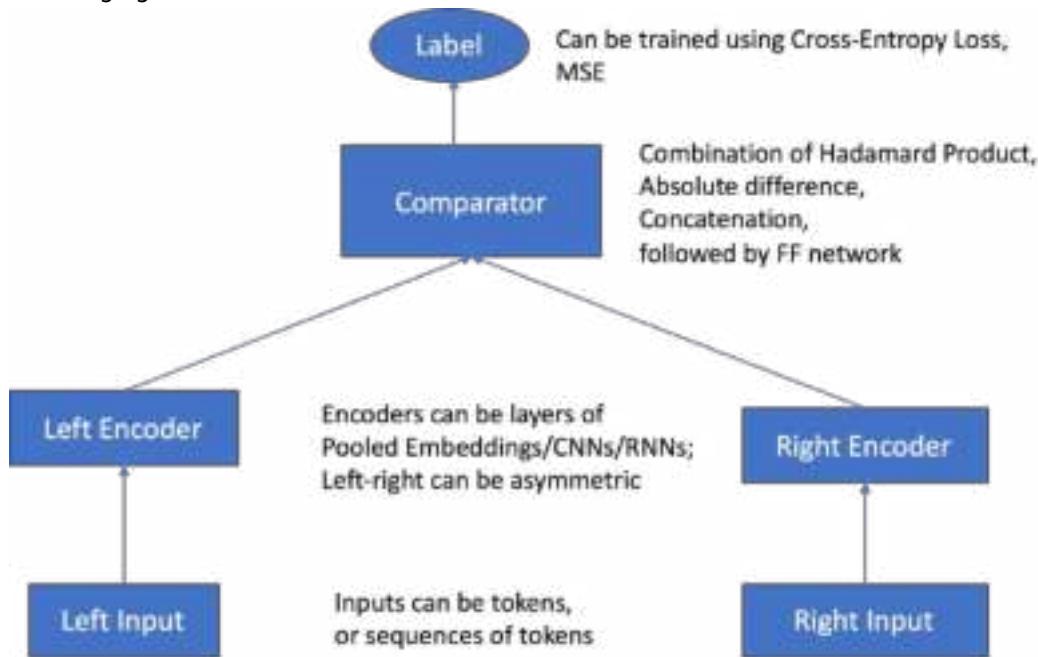

The SageMaker Object2Vec algorithm has the following main components:

- **Two input channels** – The input channels take a pair of objects of the same or different types as inputs, and pass them to independent and customizable encoders.

- **Two encoders** – The two encoders, enc0 and enc1, convert each object into a fixed-length embedding vector. The encoded embeddings of the objects in the pair are then passed into a comparator.
- **A comparator** – The comparator compares the embeddings in different ways and outputs scores that indicate the strength of the relationship between the paired objects. In the output score for a sentence pair. For example, 1 indicates a strong relationship between a sentence pair, and 0 represents a weak relationship.

During training, the algorithm accepts pairs of objects and their relationship labels or scores as inputs. The objects in each pair can be of different types, as described earlier. If the inputs to both encoders are composed of the same token-level units, you can use a shared token embedding layer by setting the `tied_token_embedding_weight` hyperparameter to `True` when you create the training job. This is possible, for example, when comparing sentences that both have word token-level units. To generate negative samples at a specified rate, set the `negative_sampling_rate` hyperparameter to the desired ratio of negative to positive samples. This hyperparameter expedites learning how to discriminate between the positive samples observed in the training data and the negative samples that are not likely to be observed.

Pairs of objects are passed through independent, customizable encoders that are compatible with the input types of corresponding objects. The encoders convert each object in a pair into a fixed-length embedding vector of equal length. The pair of vectors are passed to a comparator operator, which assembles the vectors into a single vector using the value specified in the `comparator_list` hyperparameter. The assembled vector then passes through a multilayer perceptron (MLP) layer, which produces an output that the loss function compares with the labels that you provided. This comparison evaluates the strength of the relationship between the objects in the pair as predicted by the model. The following figure shows this workflow.

Architecture of the Object2Vec Algorithm from Data Inputs to Scores

### Step 3: Produce Inferences

After the model is trained, you can use the trained encoder to preprocess input objects or to perform two types of inference:

- To convert singleton input objects into fixed-length embeddings using the corresponding encoder

- To predict the relationship label or score between a pair of input objects

The inference server automatically figures out which of the types is requested based on the input data. To get the embeddings as output, provide only one input. To predict the relationship label or score, provide both inputs in the pair.

## Object2Vec Hyperparameters

In the `CreateTrainingJob` request, you specify the training algorithm. You can also specify algorithm-specific hyperparameters as string-to-string maps. The following table lists the hyperparameters for the Object2Vec training algorithm.

Parameter Name	Description
<code>enc0_max_seq_len</code>	<p>The maximum sequence length for the enc0 encoder.</p> <p><b>Required</b></p> <p>Valid values: <math>1 \leq \text{integer} \leq 5000</math></p>
<code>enc0_vocab_size</code>	<p>The vocabulary size of enc0 tokens.</p> <p><b>Required</b></p> <p>Valid values: <math>2 \leq \text{integer} \leq 3000000</math></p>
<code>bucket_width</code>	<p>The allowed difference between data sequence length when bucketing is enabled. To enable bucketing, specify a non-zero value for this parameter.</p> <p><b>Optional</b></p> <p>Valid values: <math>0 \leq \text{integer} \leq 100</math></p> <p>Default value: 0 (no bucketing)</p>
<code>comparator_list</code>	<p>A list used to customize the way in which two embeddings are compared. The Object2Vec comparator operator layer takes the encodings from both encoders as inputs and outputs a single vector. This vector is a concatenation of subvectors. The string values passed to the <code>comparator_list</code> and the order in which they are passed determine how these subvectors are assembled. For example, if <code>comparator_list="hadamard, concat"</code>, then the comparator operator constructs the vector by concatenating the Hadamard product of two encodings and the concatenation of two encodings. If, on the other hand, <code>comparator_list="hadamard"</code>, then the comparator operator constructs the vector as the hadamard product of only two encodings.</p> <p><b>Optional</b></p> <p>Valid values: A string that contains any combination of the names of the three binary operators: <code>hadamard</code>, <code>concat</code>, or <code>abs_diff</code>. The Object2Vec algorithm currently requires that the two vector encodings have the same dimension. These operators produce the subvectors as follows:</p> <ul style="list-style-type: none"> <li>• <code>hadamard</code>: Constructs a vector as the <a href="#">Hadamard (element-wise) product</a> of two encodings.</li> </ul>

Parameter Name	Description
	<ul style="list-style-type: none"> <li>concat: Constructs a vector as the concatenation of two encodings.</li> <li>abs_diff: Constructs a vector as the absolute difference between two encodings.</li> </ul> <p>Default value: "hadamard, concat, abs_diff"</p>
dropout	<p>The dropout probability for network layers. <i>Dropout</i> is a form of regularization used in neural networks that reduces overfitting by trimming codependent neurons.</p> <p><b>Optional</b></p> <p>Valid values: <math>0.0 \leq \text{float} \leq 1.0</math></p> <p>Default value: 0.0</p>
early_stopping_patience	<p>The number of consecutive epochs without improvement allowed before early stopping is applied. Improvement is defined by with the <code>early_stopping_tolerance</code> hyperparameter.</p> <p><b>Optional</b></p> <p>Valid values: <math>1 \leq \text{integer} \leq 5</math></p> <p>Default value: 3</p>
early_stopping_tolerance	<p>The reduction in the loss function that an algorithm must achieve between consecutive epochs to avoid early stopping after the number of consecutive epochs specified in the <code>early_stopping_patience</code> hyperparameter concludes.</p> <p><b>Optional</b></p> <p>Valid values: <math>0.000001 \leq \text{float} \leq 0.1</math></p> <p>Default value: 0.01</p>
enc_dim	<p>The dimension of the output of the embedding layer.</p> <p><b>Optional</b></p> <p>Valid values: <math>4 \leq \text{integer} \leq 10000</math></p> <p>Default value: 4096</p>

Parameter Name	Description
enc0_network	<p>The network model for the enc0 encoder.</p> <p><b>Optional</b></p> <p>Valid values: hcnn, bilstm, or pooled_embedding</p> <ul style="list-style-type: none"> <li>• hcnn: A hierarchical convolutional neural network.</li> <li>• bilstm: A bidirectional long short-term memory network (biLSTM), in which the signal propagates backward and forward in time. This is an appropriate recurrent neural network (RNN) architecture for sequential learning tasks.</li> <li>• pooled_embedding: Averages the embeddings of all of the tokens in the input.</li> </ul> <p>Default value: hcnn</p>
enc0_cnn_filter_width	<p>The filter width of the convolutional neural network (CNN) enc0 encoder.</p> <p><b>Conditional</b></p> <p>Valid values: <math>1 \leq \text{integer} \leq 9</math></p> <p>Default value: 3</p>
enc0_freeze_pretrained_embedding	<p>Whether to freeze enc0 pretrained embedding weights.</p> <p><b>Conditional</b></p> <p>Valid values: True or False</p> <p>Default value: True</p>
enc0_layers	<p>The number of layers in the enc0 encoder.</p> <p><b>Conditional</b></p> <p>Valid values: auto or <math>1 \leq \text{integer} \leq 4</math></p> <ul style="list-style-type: none"> <li>• For hcnn, auto means 4.</li> <li>• For bilstm, auto means 1.</li> <li>• For pooled_embedding, auto ignores the number of layers.</li> </ul> <p>Default value: auto</p>
enc0_pretrained_embedding_file	<p>filename of the pretrained enc0 token embedding file in the auxiliary data channel.</p> <p><b>Conditional</b></p> <p>Valid values: String with alphanumeric characters, underscore, or period. [A-Za-z0-9\.\_\_]</p> <p>Default value: "" (empty string)</p>

Parameter Name	Description
enc0_token_embedding_dim	<p>The output dimension of the enc0 token embedding layer.</p> <p><b>Conditional</b></p> <p>Valid values: <math>2 \leq \text{integer} \leq 1000</math></p> <p>Default value: 300</p>
enc0_vocab_file	<p>The vocabulary file for mapping pretrained enc0 token embedding vectors to numerical vocabulary IDs.</p> <p><b>Conditional</b></p> <p>Valid values: String with alphanumeric characters, underscore, or period. [A-Za-z0-9\.\_]</p> <p>Default value: "" (empty string)</p>
enc1_network	<p>The network model for the enc1 encoder. If you want the enc1 encoder to use the same network model as enc0, including the hyperparameter values, set the value to enc0.</p> <p><b>Note</b> Even when the enc0 and enc1 encoder networks have symmetric architectures, you can't shared parameter values for these networks.</p> <p><b>Optional</b></p> <p>Valid values: enc0, hcnn, bilstm, or pooled_embedding</p> <ul style="list-style-type: none"> <li>• enc0: The network model for the enc0 encoder.</li> <li>• hcnn: A hierarchical convolutional neural network.</li> <li>• bilstm: A bidirectional LSTM, in which the signal propagates backward and forward in time. This is an appropriate recurrent neural network (RNN) architecture for sequential learning tasks.</li> <li>• pooled_embedding: The averages of the embeddings of all of the tokens in the input.</li> </ul> <p>Default value: enc0</p>
enc1_cnn_filter_width	<p>The filter width of the CNN enc1 encoder.</p> <p><b>Conditional</b></p> <p>Valid values: <math>1 \leq \text{integer} \leq 9</math></p> <p>Default value: 3</p>
enc1_freeze_pretrained_embedding	<p>Whether to freeze enc1 pretrained embedding weights.</p> <p><b>Conditional</b></p> <p>Valid values: True or False</p> <p>Default value: True</p>

Parameter Name	Description
enc1_layers	<p>The number of layers in the enc1 encoder.</p> <p><b>Conditional</b></p> <p>Valid values: auto or <math>1 \leq \text{integer} \leq 4</math></p> <ul style="list-style-type: none"> <li>For hcnn, auto means 4.</li> <li>For bilstm, auto means 1.</li> <li>For pooled_embedding, auto ignores the number of layers.</li> </ul> <p>Default value: auto</p>
enc1_max_seq_len	<p>The maximum sequence length for the enc1 encoder.</p> <p><b>Conditional</b></p> <p>Valid values: <math>1 \leq \text{integer} \leq 5000</math></p>
enc1_pretrained_embedding_file	<p>The filename of the enc1 pretrained token embedding file in the auxiliary data channel.</p> <p><b>Conditional</b></p> <p>Valid values: String with alphanumeric characters, underscore, or period. [A-Za-z0-9\.\_]</p> <p>Default value: "" (empty string)</p>
enc1_token_embedding_dim	<p>The output dimension of the enc1 token embedding layer.</p> <p><b>Conditional</b></p> <p>Valid values: <math>2 \leq \text{integer} \leq 1000</math></p> <p>Default value: 300</p>
enc1_vocab_file	<p>The vocabulary file for mapping pretrained enc1 token embeddings to vocabulary IDs.</p> <p><b>Conditional</b></p> <p>Valid values: String with alphanumeric characters, underscore, or period. [A-Za-z0-9\.\_]</p> <p>Default value: "" (empty string)</p>
enc1_vocab_size	<p>The vocabulary size of enc0 tokens.</p> <p><b>Conditional</b></p> <p>Valid values: <math>2 \leq \text{integer} \leq 3000000</math></p>

Parameter Name	Description
epochs	<p>The number of epochs to run for training.</p> <p><b>Optional</b></p> <p>Valid values: <math>1 \leq \text{integer} \leq 100</math></p> <p>Default value: 30</p>
learning_rate	<p>The learning rate for training.</p> <p><b>Optional</b></p> <p>Valid values: <math>1.0E-6 \leq \text{float} \leq 1.0</math></p> <p>Default value: 0.0004</p>
mini_batch_size	<p>The batch size that the dataset is split into for an <code>optimizer</code> during training.</p> <p><b>Optional</b></p> <p>Valid values: <math>1 \leq \text{integer} \leq 10000</math></p> <p>Default value: 32</p>
mlp_activation	<p>The type of activation function for the multilayer perceptron (MLP) layer.</p> <p><b>Optional</b></p> <p>Valid values: <code>tanh</code>, <code>relu</code>, or <code>linear</code></p> <ul style="list-style-type: none"> <li>• <code>tanh</code>: Hyperbolic tangent</li> <li>• <code>relu</code>: Rectified linear unit (ReLU)</li> <li>• <code>linear</code>: Linear function</li> </ul> <p>Default value: <code>linear</code></p>
mlp_dim	<p>The dimension of the output from MLP layers.</p> <p><b>Optional</b></p> <p>Valid values: <math>2 \leq \text{integer} \leq 10000</math></p> <p>Default value: 512</p>
mlp_layers	<p>The number of MLP layers in the network.</p> <p><b>Optional</b></p> <p>Valid values: <math>0 \leq \text{integer} \leq 10</math></p> <p>Default value: 2</p>

Parameter Name	Description
<code>negative_sampling_rate</code>	<p>The ratio of negative samples, generated to assist in training the algorithm, to positive samples that are provided by users. Negative samples represent data that is unlikely to occur in reality and are labelled negatively for training. They facilitate training a model to discriminate between the positive samples observed and the negative samples that are not. To specify the ratio of negative samples to positive samples used for training, set the value to a positive integer. For example, if you train the algorithm on input data in which all of the samples are positive and set <code>negative_sampling_rate</code> to 2, the Object2Vec algorithm internally generates two negative samples per positive sample. If you don't want to generate or use negative samples during training, set the value to 0.</p> <p><b>Optional</b></p> <p>Valid values: <math>0 \leq \text{integer}</math></p> <p>Default value: 0 (off)</p>
<code>num_classes</code>	<p>The number of classes for classification training. Amazon SageMaker ignores this hyperparameter for regression problems.</p> <p><b>Optional</b></p> <p>Valid values: <math>2 \leq \text{integer} \leq 30</math></p> <p>Default value: 2</p>
<code>optimizer</code>	<p>The optimizer type.</p> <p><b>Optional</b></p> <p>Valid values: <code>adadelta</code>, <code>adagrad</code>, <code>adam</code>, <code>sgd</code>, or <code>rmsprop</code>.</p> <ul style="list-style-type: none"> <li>• <code>adadelta</code>: A <a href="#">per-dimension learning rate method for gradient descent</a></li> <li>• <code>adagrad</code>: The <a href="#">adaptive gradient algorithm</a></li> <li>• <code>adam</code>: The <a href="#">adaptive moment estimation algorithm</a></li> <li>• <code>sgd</code>: <a href="#">Stochastic gradient descent</a></li> <li>• <code>rmsprop</code>: <a href="#">Root mean square propagation</a></li> </ul> <p>Default value: <code>adam</code></p>

Parameter Name	Description
output_layer	<p>The type of output layer where you specify that the task is regression or classification.</p> <p><b>Optional</b></p> <p>Valid values: <code>softmax</code> or <code>mean_squared_error</code></p> <ul style="list-style-type: none"> <li>• <code>softmax</code>: The <a href="#">Softmax function</a> used for classification.</li> <li>• <code>mean_squared_error</code>: The <a href="#">MSE</a> used for regression.</li> </ul> <p>Default value: <code>softmax</code></p>
tied_token_embedding_weight	<p>Whether to use a shared embedding layer for both encoders. If the inputs to both encoders use the same token-level units, use a shared token embedding layer. For example, for a collection of documents, if one encoder encodes sentences and another encodes whole documents, you can use a shared token embedding layer. That's because both sentences and documents are composed of word tokens from the same vocabulary.</p> <p><b>Optional</b></p> <p>Valid values: <code>True</code> or <code>False</code></p> <p>Default value: <code>False</code></p>
token_embedding_storage_type	<p>The mode of gradient update used during training: when the <code>dense</code> mode is used, the optimizer calculates the full gradient matrix for the token embedding layer even if most rows of the gradient are zero-valued. When <code>sparse</code> mode is used, the optimizer only stores rows of the gradient that are actually being used in the mini-batch. If you want the algorithm to perform lazy gradient updates, which calculate the gradients only in the non-zero rows and which speed up training, specify <code>row_sparse</code>. Setting the value to <code>row_sparse</code> constrains the values available for other hyperparameters, as follows:</p> <ul style="list-style-type: none"> <li>• The optimizer hyperparameter must be set to <code>adam</code>, <code>adagrad</code>, or <code>sgd</code>. Otherwise, the algorithm throws a <code>CustomerValueError</code>.</li> <li>• The algorithm automatically disables bucketing, setting the <code>bucket_width</code> hyperparameter to 0.</li> </ul> <p><b>Optional</b></p> <p>Valid values: <code>dense</code> or <code>row_sparse</code></p> <p>Default value: <code>dense</code></p>

Parameter Name	Description
weight_decay	<p>The weight decay parameter used for optimization.</p> <p><b>Optional</b></p> <p>Valid values: <math>0 \leq \text{float} \leq 10000</math></p> <p>Default value: 0 (no decay)</p>

## Tune an Object2Vec Model

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. For the objective metric, you use one of the metrics that the algorithm computes. Automatic model tuning searches the chosen hyperparameters to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker \(p. 1745\)](#).

### Metrics Computed by the Object2Vec Algorithm

The Object2Vec algorithm has both classification and regression metrics. The `output_layer` type determines which metric you can use for automatic model tuning.

#### Regressor Metrics Computed by the Object2Vec Algorithm

The algorithm reports a mean squared error regressor metric, which is computed during testing and validation. When tuning the model for regression tasks, choose this metric as the objective.

Metric Name	Description	Optimization Direction
<code>test:mean_squared_error</code>	The Mean Square Error	Minimize
<code>validation:mean_squared_error</code>	The Mean Square Error	Minimize

#### Classification Metrics Computed by the Object2Vec Algorithm

The Object2Vec algorithm reports accuracy and cross-entropy classification metrics, which are computed during test and validation. When tuning the model for classification tasks, choose one of these as the objective.

Metric Name	Description	Optimization Direction
<code>test:accuracy</code>	Accuracy	Maximize
<code>test:cross_entropy</code>	Cross-entropy	Minimize
<code>validation:accuracy</code>	Accuracy	Maximize
<code>validation:cross_entropy</code>	Cross-entropy	Minimize

### Tunable Object2Vec Hyperparameters

You can tune the following hyperparameters for the Object2Vec algorithm.

Hyperparameter Name	Hyperparameter Type	Recommended Ranges and Values	
dropout	ContinuousParameterRange	MinValue: 0.0, MaxValue: 1.0	
early_stopping_patience	IntegerParameterRange	MinValue: 1, MaxValue: 5	
early_stopping_tolerance	ContinuousParameterRange	MinValue: 0.001, MaxValue: 0.1	
enc_dim	IntegerParameterRange	MinValue: 4, MaxValue: 4096	
enc0_cnn_filter_width	IntegerParameterRange	MinValue: 1, MaxValue: 5	
enc0_layers	IntegerParameterRange	MinValue: 1, MaxValue: 4	
enc0_token_embedding_size	IntegerParameterRange	MinValue: 5, MaxValue: 300	
enc1_cnn_filter_width	IntegerParameterRange	MinValue: 1, MaxValue: 5	
enc1_layers	IntegerParameterRange	MinValue: 1, MaxValue: 4	
enc1_token_embedding_size	IntegerParameterRange	MinValue: 5, MaxValue: 300	
epochs	IntegerParameterRange	MinValue: 4, MaxValue: 20	
learning_rate	ContinuousParameterRange	MinValue: 1e-6, MaxValue: 1.0	
mini_batch_size	IntegerParameterRange	MinValue: 1, MaxValue: 8192	
mlp_activation	CategoricalParameterRanges	[tanh, relu, linear]	
mlp_dim	IntegerParameterRange	MinValue: 16, MaxValue: 1024	
mlp_layers	IntegerParameterRange	MinValue: 1, MaxValue: 4	
optimizer	CategoricalParameterRanges	[adagrad, adam, rmsprop, sgd, adadelta]	
weight_decay	ContinuousParameterRange	MinValue: 0.0, MaxValue: 1.0	

## Data Formats for Object2Vec Training

### Input: JSON Lines Request Format

Content-type: application/jsonlines

```
{"label": 0, "in0": [6, 17, 606, 19, 53, 67, 52, 12, 5, 10, 15, 10178, 7, 33, 652, 80, 15, 69, 821, 4], "in1": [16, 21, 13, 45, 14, 9, 80, 59, 164, 4]}  
{"label": 1, "in0": [22, 1016, 32, 13, 25, 11, 5, 64, 573, 45, 5, 80, 15, 67, 21, 7, 9, 107, 4], "in1": [22, 32, 13, 25, 1016, 573, 3252, 4]}  
{"label": 1, "in0": [774, 14, 21, 206], "in1": [21, 366, 125]}
```

The “in0” and “in1” are the inputs for encoder0 and encoder1, respectively. The same format is valid for both classification and regression problems. For regression, the field “label” can accept real valued inputs.

## Data Formats for Object2Vec Inference

### GPU optimization: Classification or Regression

Due to GPU memory scarcity, the INFERENCER\_PREFERRED\_MODE environment variable can be specified to optimize on whether the classification/regression or the [the section called “Output: Encoder Embeddings” \(p. 1479\)](#) inference network is loaded into GPU. If the majority of your inference is for classification or regression, specify INFERENCER\_PREFERRED\_MODE=classification. The following is a Batch Transform example of using 4 instances of p3.2xlarge that optimizes for classification/regression inference:

```
transformer = o2v.transformer(instance_count=4,  
                             instance_type="ml.p2.xlarge",  
                             max_concurrent_transforms=2,  
                             max_payload=1, # 1MB  
                             strategy='MultiRecord',  
                             env={'INFERENCER_PREFERRED_MODE': 'classification'}, # only  
                             useful with GPU  
                             output_path=output_s3_path)
```

### Input: Classification or Regression Request Format

Content-type: application/json

```
{  
    "instances" : [  
        {"in0": [6, 17, 606, 19, 53, 67, 52, 12, 5, 10, 15, 10178, 7, 33, 652, 80, 15, 69, 821, 4], "in1": [16, 21, 13, 45, 14, 9, 80, 59, 164, 4]},  
        {"in0": [22, 1016, 32, 13, 25, 11, 5, 64, 573, 45, 5, 80, 15, 67, 21, 7, 9, 107, 4], "in1": [22, 32, 13, 25, 1016, 573, 3252, 4]},  
        {"in0": [774, 14, 21, 206], "in1": [21, 366, 125]}  
    ]  
}
```

Content-type: application/jsonlines

```
{"in0": [6, 17, 606, 19, 53, 67, 52, 12, 5, 10, 15, 10178, 7, 33, 652, 80, 15, 69, 821, 4], "in1": [16, 21, 13, 45, 14, 9, 80, 59, 164, 4]}  
{"in0": [22, 1016, 32, 13, 25, 11, 5, 64, 573, 45, 5, 80, 15, 67, 21, 7, 9, 107, 4], "in1": [22, 32, 13, 25, 1016, 573, 3252, 4]}  
{"in0": [774, 14, 21, 206], "in1": [21, 366, 125]}
```

For classification problems, the length of the scores vector corresponds to `num_classes`. For regression problems, the length is 1.

### Output: Classification or Regression Response Format

Accept: application/json

```
{
    "predictions": [
        {
            "scores": [
                0.6533935070037842,
                0.07582679390907288,
                0.2707797586917877
            ]
        },
        {
            "scores": [
                0.026291321963071823,
                0.6577019095420837,
                0.31600672006607056
            ]
        }
    ]
}
```

Accept: application/jsonlines

```
{"scores": [0.195667684078216, 0.395351558923721, 0.408980727195739]}
{"scores": [0.251988261938095, 0.258233487606048, 0.489778339862823]}
{"scores": [0.280087798833847, 0.368331134319305, 0.351581096649169]}
```

In both the classification and regression formats, the scores apply to individual labels.

### Encoder Embeddings for Object2Vec

#### GPU optimization: Encoder Embeddings

An embedding is a mapping from discrete objects, such as words, to vectors of real numbers.

Due to GPU memory scarcity, the `INFERENCER_PREFERRED_MODE` environment variable can be specified to optimize on whether the [the section called “Inference Formats: Scoring” \(p. 1477\)](#) or the encoder embedding inference network is loaded into GPU. If the majority of your inference is for encoder embeddings, specify `INFERENCER_PREFERRED_MODE=embedding`. The following is a Batch Transform example of using 4 instances of p3.2xlarge that optimizes for encoder embedding inference:

```
transformer = o2v.transformer(instance_count=4,
                             instance_type="ml.p2.xlarge",
                             max_concurrent_transforms=2,
                             max_payload=1, # 1MB
                             strategy='MultiRecord',
                             env={'INFERENCER_PREFERRED_MODE': 'embedding'}, # only useful
                             with GPU
                             output_path=output_s3_path)
```

### Input: Encoder Embeddings

Content-type: application/json; infer\_max\_seqlens=<FWD-LENGTH>,<BCK-LENGTH>

Where <FWD-LENGTH> and <BCK-LENGTH> are integers in the range [1,5000] and define the maximum sequence lengths for the forward and backward encoder.

```
{
  "instances" : [
    {"in0": [6, 17, 606, 19, 53, 67, 52, 12, 5, 10, 15, 10178, 7, 33, 652, 80, 15, 69, 821, 4]}, {
      {"in0": [22, 1016, 32, 13, 25, 11, 5, 64, 573, 45, 5, 80, 15, 67, 21, 7, 9, 107, 4]}, {
        {"in0": [774, 14, 21, 206]}
    ]
  }
}
```

Content-type: application/jsonlines; infer\_max\_seqlens=<FWD-LENGTH>,<BCK-LENGTH>

Where <FWD-LENGTH> and <BCK-LENGTH> are integers in the range [1,5000] and define the maximum sequence lengths for the forward and backward encoder.

```
{"in0": [6, 17, 606, 19, 53, 67, 52, 12, 5, 10, 15, 10178, 7, 33, 652, 80, 15, 69, 821, 4]}
{"in0": [22, 1016, 32, 13, 25, 11, 5, 64, 573, 45, 5, 80, 15, 67, 21, 7, 9, 107, 4]}
{"in0": [774, 14, 21, 206]}
```

In both of these formats, you specify only one input type: “in0” or “in1.” The inference service then invokes the corresponding encoder and outputs the embeddings for each of the instances.

### Output: Encoder Embeddings

Content-type: application/json

```
{
  "predictions": [
    {"embeddings":
[0.057368703186511,0.030703511089086,0.099890425801277,0.063688032329082,0.026327300816774,0.0036375711
      {"embeddings":
[0.150190666317939,0.05145975202322,0.098204270005226,0.064249359071254,0.056249320507049,0.01513972133
    ]
  }
}
```

Content-type: application/jsonlines

```
{"embeddings":
[0.057368703186511,0.030703511089086,0.099890425801277,0.063688032329082,0.026327300816774,0.0036375711
{"embeddings":
[0.150190666317939,0.05145975202322,0.098204270005226,0.064249359071254,0.056249320507049,0.01513972133}
```

The vector length of the embeddings output by the inference service is equal to the value of one of the following hyperparameters that you specify at training time: enc0\_token\_embedding\_dim, enc1\_token\_embedding\_dim, or enc\_dim.

## Object Detection Algorithm

The Amazon SageMaker Object Detection algorithm detects and classifies objects in images using a single deep neural network. It is a supervised learning algorithm that takes images as input and identifies all instances of objects within the image scene. The object is categorized into one of the classes in a specified collection with a confidence score that it belongs to the class. Its location and scale in the image are indicated by a rectangular bounding box. It uses the [Single Shot multibox Detector \(SSD\)](#) framework and supports two base networks: [VGG](#) and [ResNet](#). The network can be trained from scratch, or trained with models that have been pre-trained on the [ImageNet](#) dataset.

## Input/Output Interface for the Object Detection Algorithm

The SageMaker Object Detection algorithm supports both RecordIO (`application/x-recordio`) and image (`image/png`, `image/jpeg`, and `application/x-image`) content types for training in file mode and supports RecordIO (`application/x-recordio`) for training in pipe mode. However you can also train in pipe mode using the image files (`image/png`, `image/jpeg`, and `application/x-image`), without creating RecordIO files, by using the augmented manifest format. The recommended input format for the Amazon SageMaker object detection algorithms is [Apache MXNet RecordIO](#). However, you can also use raw images in `.jpg` or `.png` format. The algorithm supports only `application/x-image` for inference.

### Note

To maintain better interoperability with existing deep learning frameworks, this differs from the protobuf data formats commonly used by other Amazon SageMaker algorithms.

See the [Object Detection Sample Notebooks \(p. 1482\)](#) for more details on data formats.

### Train with the RecordIO Format

If you use the RecordIO format for training, specify both train and validation channels as values for the `InputDataConfig` parameter of the [CreateTrainingJob](#) request. Specify one RecordIO (.rec) file in the train channel and one RecordIO file in the validation channel. Set the content type for both channels to `application/x-recordio`. An example of how to generate RecordIO file can be found in the object detection sample notebook. You can also use tools from the [MXNet's GluonCV](#) to generate RecordIO files for popular datasets like the [PASCAL Visual Object Classes](#) and [Common Objects in Context \(COCO\)](#).

### Train with the Image Format

If you use the image format for training, specify `train`, `validation`, `train_annotation`, and `validation_annotation` channels as values for the `InputDataConfig` parameter of [CreateTrainingJob](#) request. Specify the individual image data (.jpg or .png) files for the train and validation channels. For annotation data, you can use the JSON format. Specify the corresponding .json files in the `train_annotation` and `validation_annotation` channels. Set the content type for all four channels to `image/png` or `image/jpeg` based on the image type. You can also use the content type `application/x-image` when your dataset contains both .jpg and .png images. The following is an example of a .json file.

```
{  
    "file": "your_image_directory/sample_image1.jpg",  
    "image_size": [  
        {  
            "width": 500,  
            "height": 400,  
            "depth": 3  
        }  
    ],  
    "annotations": [  
        {  
            "class_id": 0,  
            "left": 111,  
            "top": 134,  
            "width": 61,  
            "height": 128  
        }  
    ]  
}
```

```

},
{
    "class_id": 0,
    "left": 161,
    "top": 250,
    "width": 79,
    "height": 143
},
{
    "class_id": 1,
    "left": 101,
    "top": 185,
    "width": 42,
    "height": 130
}
],
"categories": [
{
    "class_id": 0,
    "name": "dog"
},
{
    "class_id": 1,
    "name": "cat"
}
]
}

```

Each image needs a .json file for annotation, and the .json file should have the same name as the corresponding image. The name of above .json file should be "sample\_image1.json". There are four properties in the annotation .json file. The property "file" specifies the relative path of the image file. For example, if your training images and corresponding .json files are stored in s3://*your\_bucket*/train/sample\_image and s3://*your\_bucket*/train\_annotation, specify the path for your train and train\_annotation channels as s3://*your\_bucket*/train and s3://*your\_bucket*/train\_annotation, respectively.

In the .json file, the relative path for an image named sample\_image1.jpg should be sample\_image/sample\_image1.jpg. The "image\_size" property specifies the overall image dimensions. The SageMaker object detection algorithm currently only supports 3-channel images. The "annotations" property specifies the categories and bounding boxes for objects within the image. Each object is annotated by a "class\_id" index and by four bounding box coordinates ("left", "top", "width", "height"). The "left" (x-coordinate) and "top" (y-coordinate) values represent the upper-left corner of the bounding box. The "width" (x-coordinate) and "height" (y-coordinate) values represent the dimensions of the bounding box. The origin (0, 0) is the upper-left corner of the entire image. If you have multiple objects within one image, all the annotations should be included in a single .json file. The "categories" property stores the mapping between the class index and class name. The class indices should be numbered successively and the numbering should start with 0. The "categories" property is optional for the annotation .json file

### Train with Augmented Manifest Image Format

The augmented manifest format enables you to do training in pipe mode using image files without needing to create RecordIO files. You need to specify both train and validation channels as values for the `InputDataConfig` parameter of the `CreateTrainingJob` request. While using the format, an S3 manifest file needs to be generated that contains the list of images and their corresponding annotations. The manifest file format should be in `JSON Lines` format in which each line represents one sample. The images are specified using the '`source-ref`' tag that points to the S3 location of the image. The annotations are provided under the "`AttributeNames`" parameter value as specified in the `CreateTrainingJob` request. It can also contain additional metadata under the `metadata` tag, but these are ignored by the algorithm. In the following example, the "`AttributeNames`" are contained in the list [`"source-ref"`, `"bounding-box"`]:

```
{"source-ref": "s3://your_bucket/image1.jpg", "bounding-box": {"image_size": [{"width": 500, "height": 400, "depth": 3}], "annotations": [{"class_id": 0, "left": 111, "top": 134, "width": 61, "height": 128}, {"class_id": 5, "left": 161, "top": 250, "width": 80, "height": 50}]}, "bounding-box-metadata": {"class-map": {"0": "dog", "5": "horse"}, "type": "groundtruth/object-detection"}}, {"source-ref": "s3://your_bucket/image2.jpg", "bounding-box": {"image_size": [{"width": 400, "height": 300, "depth": 3}], "annotations": [{"class_id": 1, "left": 100, "top": 120, "width": 43, "height": 78}]}, "bounding-box-metadata": {"class-map": {"1": "cat"}, "type": "groundtruth/object-detection"}}}
```

The order of "AttributeNames" in the input files matters when training the Object Detection algorithm. It accepts piped data in a specific order, with `image` first, followed by `annotations`. So the "AttributeNames" in this example are provided with "source-ref" first, followed by "bounding-box". When using Object Detection with Augmented Manifest, the value of parameter `RecordWrapperType` must be set as "RecordIO".

For more information on augmented manifest files, see [Provide Dataset Metadata to Training Jobs with an Augmented Manifest File \(p. 1864\)](#).

### Incremental Training

You can also seed the training of a new model with the artifacts from a model that you trained previously with SageMaker. Incremental training saves training time when you want to train a new model with the same or similar data. SageMaker object detection models can be seeded only with another built-in object detection model trained in SageMaker.

To use a pretrained model, in the `CreateTrainingJob` request, specify the `ChannelName` as "model" in the `InputDataConfig` parameter. Set the `ContentType` for the model channel to `application/x-sagemaker-model`. The input hyperparameters of both the new model and the pretrained model that you upload to the model channel must have the same settings for the `base_network` and `num_classes` input parameters. These parameters define the network architecture. For the pretrained model file, use the compressed model artifacts (in `.tar.gz` format) output by SageMaker. You can use either RecordIO or image formats for input data.

For a sample notebook that shows how to use incremental training with the SageMaker object detection algorithm, see [SageMaker Object Detection Incremental Training](#) sample notebook. For more information on incremental training and for instructions on how to use it, see [Incremental Training in Amazon SageMaker \(p. 1855\)](#).

### EC2 Instance Recommendation for the Object Detection Algorithm

For object detection, we support the following GPU instances for training: `ml.p2.xlarge`, `ml.p2.8xlarge`, `ml.p2.16xlarge`, `ml.p3.2xlarge`, `ml.p3.8xlarge` and `ml.p3.16xlarge`. We recommend using GPU instances with more memory for training with large batch sizes. You can also run the algorithm on multi-GPU and multi-machine settings for distributed training. However, both CPU (such as C5 and M5) and GPU (such as P2 and P3) instances can be used for the inference. All the supported instance types for inference are itemized on [Amazon SageMaker ML Instance Types](#).

### Object Detection Sample Notebooks

For a sample notebook that shows how to use the SageMaker Object Detection algorithm to train and host a model on the COCO dataset using the Single Shot multibox Detector algorithm, see [Object Detection using the Image and JSON format](#). For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see [Use Amazon SageMaker Notebook Instances \(p. 120\)](#). Once you have created a notebook instance and opened it, select the `SageMaker Examples` tab to see a list of all the SageMaker samples. The object detection example notebook using the Object Detection algorithm is located in the `Introduction to Amazon Algorithms` section. To open a notebook, click on its `Use` tab and select `Create copy`.

## How Object Detection Works

The object detection algorithm identifies and locates all instances of objects in an image from a known collection of object categories. The algorithm takes an image as input and outputs the category that the object belongs to, along with a confidence score that it belongs to the category. The algorithm also predicts the object's location and scale with a rectangular bounding box. Amazon SageMaker Object Detection uses the [Single Shot multibox Detector \(SSD\)](#) algorithm that takes a convolutional neural network (CNN) pretrained for classification task as the base network. SSD uses the output of intermediate layers as features for detection.

Various CNNs such as [VGG](#) and [ResNet](#) have achieved great performance on the image classification task. Object detection in Amazon SageMaker supports both VGG-16 and ResNet-50 as a base network for SSD. The algorithm can be trained in full training mode or in transfer learning mode. In full training mode, the base network is initialized with random weights and then trained on user data. In transfer learning mode, the base network weights are loaded from pretrained models.

The object detection algorithm uses standard data augmentation operations, such as flip, rescale, and jitter, on the fly internally to help avoid overfitting.

## Object Detection Hyperparameters

In the [CreateTrainingJob](#) request, you specify the training algorithm that you want to use. You can also specify algorithm-specific hyperparameters that are used to help estimate the parameters of the model from a training dataset. The following table lists the hyperparameters provided by Amazon SageMaker for training the object detection algorithm. For more information about how object training works, see [How Object Detection Works \(p. 1483\)](#).

Parameter Name	Description
<code>num_classes</code>	<p>The number of output classes. This parameter defines the dimensions of the network output and is typically set to the number of classes in the dataset.</p> <p><b>Required</b></p> <p>Valid values: positive integer</p>
<code>num_training_samples</code>	<p>The number of training examples in the input dataset.</p> <p><b>Note</b> If there is a mismatch between this value and the number of samples in the training set, then the behavior of the <code>lr_scheduler_step</code> parameter will be undefined and distributed training accuracy may be affected.</p> <p><b>Required</b></p> <p>Valid values: positive integer</p>
<code>base_network</code>	<p>The base network architecture to use.</p> <p><b>Optional</b></p> <p>Valid values: 'vgg-16' or 'resnet-50'</p> <p>Default value: 'vgg-16'</p>
<code>early_stopping</code>	True to use early stopping logic during training. False not to use it.

Parameter Name	Description
	<b>Optional</b> Valid values: <code>True</code> or <code>False</code> Default value: <code>False</code>
<code>early_stopping_min_epochs</code>	The minimum number of epochs that must be run before the early stopping logic can be invoked. It is used only when <code>early_stopping = True</code> . <b>Optional</b> Valid values: positive integer Default value: 10
<code>early_stopping_patience</code>	The number of epochs to wait before ending training if no improvement, as defined by the <code>early_stopping_tolerance</code> hyperparameter, is made in the relevant metric. It is used only when <code>early_stopping = True</code> . <b>Optional</b> Valid values: positive integer Default value: 5
<code>early_stopping_tolerance</code>	The tolerance value that the relative improvement in <code>validation:mAP</code> , the mean average precision (mAP), is required to exceed to avoid early stopping. If the ratio of the change in the mAP divided by the previous best mAP is smaller than the <code>early_stopping_tolerance</code> value set, early stopping considers that there is no improvement. It is used only when <code>early_stopping = True</code> . <b>Optional</b> Valid values: $0 \leq \text{float} \leq 1$ Default value: 0.0
<code>image_shape</code>	The image size for input images. We rescale the input image to a square image with this size. We recommend using 300 and 512 for better performance. <b>Optional</b> Valid values: positive integer $\geq 300$ Default: 300
<code>epochs</code>	The number of training epochs. <b>Optional</b> Valid values: positive integer Default: 30

Parameter Name	Description
<code>freeze_layer_pattern</code>	<p>The regular expression (regex) for freezing layers in the base network. For example, if we set <code>freeze_layer_pattern = "^(conv1_ conv2_).*</code>", then any layers with a name that contains "conv1_" or "conv2_" are frozen, which means that the weights for these layers are not updated during training. The layer names can be found in the network symbol files <a href="#">vgg16-symbol.json</a> and <a href="#">resnet-50-symbol.json</a>. Freezing a layer means that its weights can not be modified further. This can reduce training time significantly in exchange for modest losses in accuracy. This technique is commonly used in transfer learning where the lower layers in the base network do not need to be retrained.</p> <p><b>Optional</b></p> <p>Valid values: string</p> <p>Default: No layers frozen.</p>
<code>kv_store</code>	<p>The weight update synchronization mode used for distributed training. The weights can be updated either synchronously or asynchronously across machines. Synchronous updates typically provide better accuracy than asynchronous updates but can be slower. See the <a href="#">Distributed Training</a> MXNet tutorial for details.</p> <p><b>Note</b>  This parameter is not applicable to single machine training.</p> <p><b>Optional</b></p> <p>Valid values: 'dist_sync' or 'dist_async'</p> <ul style="list-style-type: none"> <li>'dist_sync': The gradients are synchronized after every batch with all the workers. With 'dist_sync', batch-size now means the batch size used on each machine. So if there are n machines and we use batch size b, then dist_sync behaves like a single machine with batch size n*b.</li> <li>'dist_async': Performs asynchronous updates. The weights are updated whenever gradients are received from any machine and the weight updates are atomic. However, the order is not guaranteed.</li> </ul> <p>Default: -</p>

Parameter Name	Description
<code>label_width</code>	<p>The force padding label width used to sync across training and validation data. For example, if one image in the data contains at most 10 objects, and each object's annotation is specified with 5 numbers, [class_id, left, top, width, height], then the <code>label_width</code> should be no smaller than <math>(10*5 + \text{header information length})</math>. The header information length is usually 2. We recommend using a slightly larger <code>label_width</code> for the training, such as 60 for this example.</p> <p><b>Optional</b></p> <p>Valid values: Positive integer large enough to accommodate the largest annotation information length in the data.</p> <p>Default: 350</p>
<code>learning_rate</code>	<p>The initial learning rate.</p> <p><b>Optional</b></p> <p>Valid values: float in (0, 1]</p> <p>Default: 0.001</p>
<code>lr_scheduler_factor</code>	<p>The ratio to reduce learning rate. Used in conjunction with the <code>lr_scheduler_step</code> parameter defined as <math>\text{lr\_new} = \text{lr\_old} * \text{lr\_scheduler\_factor}</math>.</p> <p><b>Optional</b></p> <p>Valid values: float in (0, 1)</p> <p>Default: 0.1</p>
<code>lr_scheduler_step</code>	<p>The epochs at which to reduce the learning rate. The learning rate is reduced by <code>lr_scheduler_factor</code> at epochs listed in a comma-delimited string: "epoch1, epoch2, ...". For example, if the value is set to "10, 20" and the <code>lr_scheduler_factor</code> is set to 1/2, then the learning rate is halved after 10th epoch and then halved again after 20th epoch.</p> <p><b>Optional</b></p> <p>Valid values: string</p> <p>Default: empty string</p>

Parameter Name	Description
mini_batch_size	<p>The batch size for training. In a single-machine multi-gpu setting, each GPU handles <code>mini_batch_size/num_gpu</code> training samples. For the multi-machine training in <code>dist_sync</code> mode, the actual batch size is <code>mini_batch_size*number of machines</code>. A large <code>mini_batch_size</code> usually leads to faster training, but it may cause out of memory problem. The memory usage is related to <code>mini_batch_size</code>, <code>image_shape</code>, and <code>base_network</code> architecture. For example, on a single p3.2xlarge instance, the largest <code>mini_batch_size</code> without an out of memory error is 32 with the <code>base_network</code> set to "resnet-50" and an <code>image_shape</code> of 300. With the same instance, you can use 64 as the <code>mini_batch_size</code> with the base network vgg-16 and an <code>image_shape</code> of 300.</p> <p><b>Optional</b></p> <p>Valid values: positive integer</p> <p>Default: 32</p>
momentum	<p>The momentum for sgd. Ignored for other optimizers.</p> <p><b>Optional</b></p> <p>Valid values: float in (0, 1]</p> <p>Default: 0.9</p>
nms_threshold	<p>The non-maximum suppression threshold.</p> <p><b>Optional</b></p> <p>Valid values: float in (0, 1]</p> <p>Default: 0.45</p>
optimizer	<p>The optimizer types. For details on optimizer values, see <a href="#">MXNet's API</a>.</p> <p><b>Optional</b></p> <p>Valid values: ['sgd', 'adam', 'rmsprop', 'adadelta']</p> <p>Default: 'sgd'</p>
overlap_threshold	<p>The evaluation overlap threshold.</p> <p><b>Optional</b></p> <p>Valid values: float in (0, 1]</p> <p>Default: 0.5</p>

Parameter Name	Description
use_pretrained_model	<p>Indicates whether to use a pre-trained model for training. If set to 1, then the pre-trained model with corresponding architecture is loaded and used for training. Otherwise, the network is trained from scratch.</p> <p><b>Optional</b></p> <p>Valid values: 0 or 1</p> <p>Default: 1</p>
weight_decay	<p>The weight decay coefficient for sgd and rmsprop. Ignored for other optimizers.</p> <p><b>Optional</b></p> <p>Valid values: float in (0, 1)</p> <p>Default: 0.0005</p>

## Tune an Object Detection Model

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker \(p. 1745\)](#).

### Metrics Computed by the Object Detection Algorithm

The object detection algorithm reports on a single metric during training: validation:mAP. When tuning a model, choose this metric as the objective metric.

Metric Name	Description	Optimization Direction
validation:mAP	Mean Average Precision (mAP) computed on the validation set.	Maximize

### Tunable Object Detection Hyperparameters

Tune the Amazon SageMaker object detection model with the following hyperparameters. The hyperparameters that have the greatest impact on the object detection objective metric are: mini\_batch\_size, learning\_rate, and optimizer.

Parameter Name	Parameter Type	Recommended Ranges
learning_rate	ContinuousParameterRange	MinValue: 1e-6, MaxValue: 0.5
mini_batch_size	IntegerParameterRanges	MinValue: 8, MaxValue: 64

Parameter Name	Parameter Type	Recommended Ranges
momentum	ContinuousParameterRange	MinValue: 0.0, MaxValue: 0.999
optimizer	CategoricalParameterRanges	['sgd', 'adam', 'rmsprop', 'adadelta']
weight_decay	ContinuousParameterRange	MinValue: 0.0, MaxValue: 0.999

## Object Detection Request and Response Formats

### Request Format

Query a trained model by using the model's endpoint. The endpoint takes .jpg and .png image formats with `image/jpeg` and `image/png` content-types.

### Response Formats

The response is the class index with a confidence score and bounding box coordinates for all objects within the image encoded in JSON format. The following is an example of response .json file:

```
{"prediction": [
    [4.0, 0.86419455409049988, 0.3088374733924866, 0.07030484080314636, 0.7110607028007507,
     0.9345266819000244],
    [0.0, 0.73376623392105103, 0.5714187026023865, 0.40427327156066895, 0.827075183391571,
     0.9712159633636475],
    [4.0, 0.32643985450267792, 0.3677481412887573, 0.034883320331573486, 0.6318609714508057,
     0.5967587828636169],
    [8.0, 0.22552496790885925, 0.6152569651603699, 0.5722782611846924, 0.882301390171051,
     0.8985623121261597],
    [3.0, 0.42260299175977707, 0.019305512309074402, 0.08386176824569702,
     0.39093565940856934, 0.9574796557426453]
]}
```

Each row in this .json file contains an array that represents a detected object. Each of these object arrays consists of a list of six numbers. The first number is the predicted class label. The second number is the associated confidence score for the detection. The last four numbers represent the bounding box coordinates [xmin, ymin, xmax, ymax]. These output bounding box corner indices are normalized by the overall image size. Note that this encoding is different than that use by the input .json format. For example, in the first entry of the detection result, 0.3088374733924866 is the left coordinate (x-coordinate of upper-left corner) of the bounding box as a ratio of the overall image width, 0.07030484080314636 is the top coordinate (y-coordinate of upper-left corner) of the bounding box as a ratio of the overall image height, 0.7110607028007507 is the right coordinate (x-coordinate of lower-right corner) of the bounding box as a ratio of the overall image width, and 0.9345266819000244 is the bottom coordinate (y-coordinate of lower-right corner) of the bounding box as a ratio of the overall image height.

To avoid unreliable detection results, you might want to filter out the detection results with low confidence scores. In the [object detection sample notebook](#), we provide scripts to remove the low confidence detections. Scripts are also provided to plot the bounding boxes on the original image.

For batch transform, the response is in JSON format, where the format is identical to the JSON format described above. The detection results of each image is represented as a JSON file. For example:

```
{"prediction": [[label_id, confidence_score, xmin, ymin, xmax, ymax], [label_id,
confidence_score, xmin, ymin, xmax, ymax]]}
```

For more details on training and inference, see the [Object Detection Sample Notebooks \(p. 1482\)](#).

### OUTPUT: JSON Response Format

accept: application/json;annotation=1

```
{  
    "image_size": [  
        {  
            "width": 500,  
            "height": 400,  
            "depth": 3  
        }  
    ],  
    "annotations": [  
        {  
            "class_id": 0,  
            "score": 0.943,  
            "left": 111,  
            "top": 134,

            "width": 79,  
            "height": 143  
        },  
        {  
            "class_id": 1,  
            "score": 0.0133,  
            "left": 101,  
            "top": 185,  
            "width": 42,  
            "height": 130  
        }  
    ]  
}
```

## Principal Component Analysis (PCA) Algorithm

PCA is an unsupervised machine learning algorithm that attempts to reduce the dimensionality (number of features) within a dataset while still retaining as much information as possible. This is done by finding a new set of features called *components*, which are composites of the original features that are uncorrelated with one another. They are also constrained so that the first component accounts for the largest possible variability in the data, the second component the second most variability, and so on.

In Amazon SageMaker, PCA operates in two modes, depending on the scenario:

- **regular:** For datasets with sparse data and a moderate number of observations and features.
- **randomized:** For datasets with both a large number of observations and features. This mode uses an approximation algorithm.

PCA uses tabular data.

The rows represent observations you want to embed in a lower dimensional space. The columns represent features that you want to find a reduced approximation for. The algorithm calculates the

covariance matrix (or an approximation thereof in a distributed manner), and then performs the singular value decomposition on this summary to produce the principal components.

## Input/Output Interface for the PCA Algorithm

For training, PCA expects data provided in the train channel, and optionally supports a dataset passed to the test dataset, which is scored by the final algorithm. Both `recordIO-wrapped-protobuf` and `CSV` formats are supported for training. You can use either File mode or Pipe mode to train models on data that is formatted as `recordIO-wrapped-protobuf` or as `CSV`.

For inference, PCA supports `text/csv`, `application/json`, and `application/x-recordio-protobuf`. Results are returned in either `application/json` or `application/x-recordio-protobuf` format with a vector of "projections."

For more information on input and output file formats, see [PCA Response Formats \(p. 1493\)](#) for inference and the [PCA Sample Notebooks \(p. 1491\)](#).

## EC2 Instance Recommendation for the PCA Algorithm

PCA supports both GPU and CPU computation. Which instance type is most performant depends heavily on the specifics of the input data.

## PCA Sample Notebooks

For a sample notebook that shows how to use the SageMaker Principal Component Analysis algorithm to analyze the images of handwritten digits from zero to nine in the MNIST dataset, see [An Introduction to PCA with MNIST](#). For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see [Use Amazon SageMaker Notebook Instances \(p. 120\)](#). Once you have created a notebook instance and opened it, select the **SageMaker Examples** tab to see a list of all the SageMaker samples. The topic modeling example notebooks using the NTM algorithms are located in the **Introduction to Amazon algorithms** section. To open a notebook, click on its **Use** tab and select **Create copy**.

## How PCA Works

Principal Component Analysis (PCA) is a learning algorithm that reduces the dimensionality (number of features) within a dataset while still retaining as much information as possible.

PCA reduces dimensionality by finding a new set of features called *components*, which are composites of the original features, but are uncorrelated with one another. The first component accounts for the largest possible variability in the data, the second component the second most variability, and so on.

It is an unsupervised dimensionality reduction algorithm. In unsupervised learning, labels that might be associated with the objects in the training dataset aren't used.

Given the input of a matrix with rows  $\mathbb{F}_1, \dots, \mathbb{F}_n$  each of dimension  $1 \times d$ , the data is partitioned into mini-batches of rows and distributed among the training nodes (workers). Each worker then computes a summary of its data. The summaries of the different workers are then unified into a single solution at the end of the computation.

## Modes

The Amazon SageMaker PCA algorithm uses either of two modes to calculate these summaries, depending on the situation:

- **regular**: for datasets with sparse data and a moderate number of observations and features.
- **randomized**: for datasets with both a large number of observations and features. This mode uses an approximation algorithm.

As the algorithm's last step, it performs the singular value decomposition on the unified solution, from which the principal components are then derived.

### Mode 1: Regular

The workers jointly compute both  $\sum x_i^T x_i$  and  $\sum x_i$ .

#### Note

Because  $x_i$  are  $1 \times d$  row vectors,  $x_i^T x_i$  is a matrix (not a scalar). Using row vectors within the code allows us to obtain efficient caching.

The covariance matrix is computed as  $\sum x_i^T x_i - (1/n)(\sum x_i)^T \sum x_i$ , and its top `num_components` singular vectors form the model.

#### Note

If `subtract_mean` is `False`, we avoid computing and subtracting  $\sum x_i$ .

Use this algorithm when the dimension  $d$  of the vectors is small enough so that  $x_i$  can fit in memory.

### Mode 2: Randomized

When the number of features in the input dataset is large, we use a method to approximate the covariance metric. For every mini-batch  $X_i$  of dimension  $b \times d$ , we randomly initialize a  $(\text{num\_components} + \text{extra\_components}) \times b$  matrix that we multiply by each mini-batch, to create a  $(\text{num\_components} + \text{extra\_components}) \times d$  matrix. The sum of these matrices is computed by the workers, and the servers perform SVD on the final  $(\text{num\_components} + \text{extra\_components}) \times d$  matrix. The top right `num_components` singular vectors of it are the approximation of the top singular vectors of the input matrix.

Let  $t = \text{num\_components} + \text{extra\_components}$ . Given a mini-batch  $X_i$  of dimension  $b \times d$ , the worker draws a random matrix  $H_i$  of dimension  $t \times b$ . Depending on whether the environment uses a GPU or CPU and the dimension size, the matrix is either a random sign matrix where each entry is  $+/-1$  or a *FJLT* (fast Johnson Lindenstrauss transform; for information, see [FJLT Transforms](#) and the follow-up papers). The worker then computes  $H_i X_i$  and maintains  $B = \sum H_i X_i$ . The worker also maintains  $H^T$ , the sum of columns of  $H_1, \dots, H_T$  ( $T$  being the total number of mini-batches), and  $s$ , the sum of all input rows. After processing the entire shard of data, the worker sends the server  $B$ ,  $h$ ,  $s$ , and  $n$  (the number of input rows).

Denote the different inputs to the server as  $B, h, s, n$ . The server computes  $B, h, s, n$  the sums of the respective inputs. It then computes  $C = B - (1/n)h^T h$ , and finds its singular value decomposition. The top-right singular vectors and singular values of  $C$  are used as the approximate solution to the problem.

## PCA Hyperparameters

In the `CreateTrainingJob` request, you specify the training algorithm. You can also specify algorithm-specific HyperParameters as string-to-string maps. The following table lists the hyperparameters for the PCA training algorithm provided by Amazon SageMaker. For more information about how PCA works, see [How PCA Works \(p. 1491\)](#).

Parameter Name	Description
<code>feature_dim</code>	<p>Input dimension.</p> <p><b>Required</b></p> <p>Valid values: positive integer</p>
<code>mini_batch_size</code>	<p>Number of rows in a mini-batch.</p> <p><b>Required</b></p> <p>Valid values: positive integer</p>
<code>num_components</code>	<p>The number of principal components to compute.</p> <p><b>Required</b></p> <p>Valid values: positive integer</p>
<code>algorithm_mode</code>	<p>Mode for computing the principal components.</p> <p><b>Optional</b></p> <p>Valid values: <i>regular</i> or <i>randomized</i></p> <p>Default value: <i>regular</i></p>
<code>extra_components</code>	<p>As the value increases, the solution becomes more accurate but the runtime and memory consumption increase linearly. The default, -1, means the maximum of 10 and <code>num_components</code>. Valid for <i>randomized</i> mode only.</p> <p><b>Optional</b></p> <p>Valid values: Non-negative integer or -1</p> <p>Default value: -1</p>
<code>subtract_mean</code>	<p>Indicates whether the data should be unbiased both during training and at inference.</p> <p><b>Optional</b></p> <p>Valid values: One of <i>true</i> or <i>false</i></p> <p>Default value: <i>true</i></p>

## PCA Response Formats

All Amazon SageMaker built-in algorithms adhere to the common input inference format described in [Common Data Formats - Inference](#). This topic contains a list of the available output formats for the SageMaker PCA algorithm.

### JSON Response Format

Accept—application/json

{

```

    "projections": [
        {
            "projection": [1.0, 2.0, 3.0, 4.0, 5.0]
        },
        {
            "projection": [6.0, 7.0, 8.0, 9.0, 0.0]
        },
        ....
    ]
}

```

### JSONLINES Response Format

Accept—application/jsonlines

```

{ "projection": [1.0, 2.0, 3.0, 4.0, 5.0] }
{ "projection": [6.0, 7.0, 8.0, 9.0, 0.0] }

```

### RECORDIO Response Format

Accept—application/x-recordio-protobuf

```

[
    Record = {
        features = {},
        label = {
            'projection': {
                keys: [],
                values: [1.0, 2.0, 3.0, 4.0, 5.0]
            }
        }
    },
    Record = {
        features = {},
        label = {
            'projection': {
                keys: [],
                values: [1.0, 2.0, 3.0, 4.0, 5.0]
            }
        }
    }
]

```

## Random Cut Forest (RCF) Algorithm

Amazon SageMaker Random Cut Forest (RCF) is an unsupervised algorithm for detecting anomalous data points within a data set. These are observations which diverge from otherwise well-structured or patterned data. Anomalies can manifest as unexpected spikes in time series data, breaks in periodicity, or unclassifiable data points. They are easy to describe in that, when viewed in a plot, they are often easily distinguishable from the "regular" data. Including these anomalies in a data set can drastically increase the complexity of a machine learning task since the "regular" data can often be described with a simple model.

With each data point, RCF associates an anomaly score. Low score values indicate that the data point is considered "normal." High values indicate the presence of an anomaly in the data. The definitions of "low" and "high" depend on the application but common practice suggests that scores beyond three standard deviations from the mean score are considered anomalous.

While there are many applications of anomaly detection algorithms to one-dimensional time series data such as traffic volume analysis or sound volume spike detection, RCF is designed to work with arbitrary-

dimensional input. Amazon SageMaker RCF scales well with respect to number of features, data set size, and number of instances.

## Input/Output Interface for the RCF Algorithm

Amazon SageMaker Random Cut Forest supports the `train` and `test` data channels. The optional `test` channel is used to compute accuracy, precision, recall, and F1-score metrics on labeled data. Train and test data content types can be either `application/x-recordio-protobuf` or `text/csv` formats. For the test data, when using `text/csv` format, the content must be specified as `text/csv;label_size=1` where the first column of each row represents the anomaly label: "1" for an anomalous data point and "0" for a normal data point. You can use either File mode or Pipe mode to train RCF models on data that is formatted as `recordIO-wrapped-protobuf` or as CSV

Also note that the `train` channel only supports `S3DataDistributionType=ShardedByS3Key` and the `test` channel only supports `S3DataDistributionType=FullyReplicated`. The S3 distribution type can be specified using the [Amazon SageMaker Python SDK](#) as follows:

```
import sagemaker

# specify Random Cut Forest training job information and hyperparameters
rcf = sagemaker.estimator.Estimator(...)

# explicitly specify "ShardedByS3Key" distribution type
train_data = sagemaker.inputs.s3_input(
    s3_data=s3_training_data_location,
    content_type='text/csv;label_size=0',
    distribution='ShardedByS3Key')

# run the training job on input data stored in S3
rcf.fit({'train': train_data})
```

To avoid common errors around execution roles, ensure that you have the execution roles required, `AmazonSageMakerFullAccess` and `AmazonEC2ContainerRegistryFullAccess`. To avoid common errors around your image not existing or its permissions being incorrect, ensure that your ECR image is not larger than the allocated disk space on the training instance. To avoid this, run your training job on an instance that has sufficient disk space. In addition, if your ECR image is from a different Amazon account's Elastic Container Service (ECS) repository, and you do not set repository permissions to grant access, this will result in an error. See the [ECR repository permissions](#) for more information on setting a repository policy statement.

See the [S3DataSource](#) for more information on customizing the S3 data source attributes. Finally, in order to take advantage of multi-instance training the training data must be partitioned into at least as many files as instances.

For inference, RCF supports `application/x-recordio-protobuf`, `text/csv` and `application/json` input data content types. See the [Common Data Formats for Built-in Algorithms \(p. 1354\)](#)

documentation for more information. RCF inference returns application/x-recordio-protobuf or application/json formatted output. Each record in these output data contains the corresponding anomaly scores for each input data point. See [Common Data Formats--Inference](#) for more information.

For more information on input and output file formats, see [RCF Response Formats \(p. 1500\)](#) for inference and the [RCF Sample Notebooks \(p. 1496\)](#).

## Instance Recommendations for the RCF Algorithm

For training, we recommend the m1.m4, m1.c4, and m1.c5 instance families. For inference we recommend using a m1.c5.xl instance type in particular, for maximum performance as well as minimized cost per hour of usage. Although the algorithm could technically run on GPU instance types it does not take advantage of GPU hardware.

## RCF Sample Notebooks

For an example of how to train an RCF model and perform inferences with it, see the [An Introduction to SageMaker Random Cut Forests](#) notebook. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see [Use Amazon SageMaker Notebook Instances \(p. 120\)](#). Once you have created a notebook instance and opened it, select the **SageMaker Examples** tab to see a list of all the SageMaker samples. To open a notebook, click on its **Use** tab and select **Create copy**.

## How RCF Works

Amazon SageMaker Random Cut Forest (RCF) is an unsupervised algorithm for detecting anomalous data points within a dataset. These are observations which diverge from otherwise well-structured or patterned data. Anomalies can manifest as unexpected spikes in time series data, breaks in periodicity, or unclassifiable data points. They are easy to describe in that, when viewed in a plot, they are often easily distinguishable from the "regular" data. Including these anomalies in a dataset can drastically increase the complexity of a machine learning task since the "regular" data can often be described with a simple model.

The main idea behind the RCF algorithm is to create a forest of trees where each tree is obtained using a partition of a sample of the training data. For example, a random sample of the input data is first determined. The random sample is then partitioned according to the number of trees in the forest. Each tree is given such a partition and organizes that subset of points into a k-d tree. The anomaly score assigned to a data point by the tree is defined as the expected change in complexity of the tree as a result adding that point to the tree; which, in approximation, is inversely proportional to the resulting depth of the point in the tree. The random cut forest assigns an anomaly score by computing the average score from each constituent tree and scaling the result with respect to the sample size. The RCF algorithm is based on the one described in reference [1].

## Sample Data Randomly

The first step in the RCF algorithm is to obtain a random sample of the training data. In particular, suppose we want a sample of size  $K$  from  $N$  total data points. If the training data is small enough, the entire dataset can be used, and we could randomly draw  $K$  elements from this set. However, frequently the training data is too large to fit all at once, and this approach isn't feasible. Instead, we use a technique called reservoir sampling.

[Reservoir sampling](#) is an algorithm for efficiently drawing random samples from a dataset  $S = \{S_1, \dots, S_N\}$  where the elements in the dataset can only be observed one at a time or in batches. In fact, reservoir sampling works even when  $N$  is not known *a priori*. If only one sample is requested, such as when  $K = 1$ , the algorithm is like this:

### Algorithm: Reservoir Sampling

- Input: dataset or data stream  $S = \{S_1, \dots, S_N\}$
- Initialize the random sample  $X = S_1$
- For each observed sample  $S_n, n = 2, \dots, N$ :
  - Pick a uniform random number  $\xi \in [0, 1]$
  - If  $\xi < 1/n$ 
    - Set  $X = S_n$
- Return  $X$

This algorithm selects a random sample such that  $P(X = S_n) = 1/N$  for all  $n = 1, \dots, N$ . When  $K > 1$  the algorithm is more complicated. Additionally, a distinction must be made between random sampling that is with and without replacement. RCF performs an augmented reservoir sampling without replacement on the training data based on the algorithms described in [2].

### Train a RCF Model and Produce Inferences

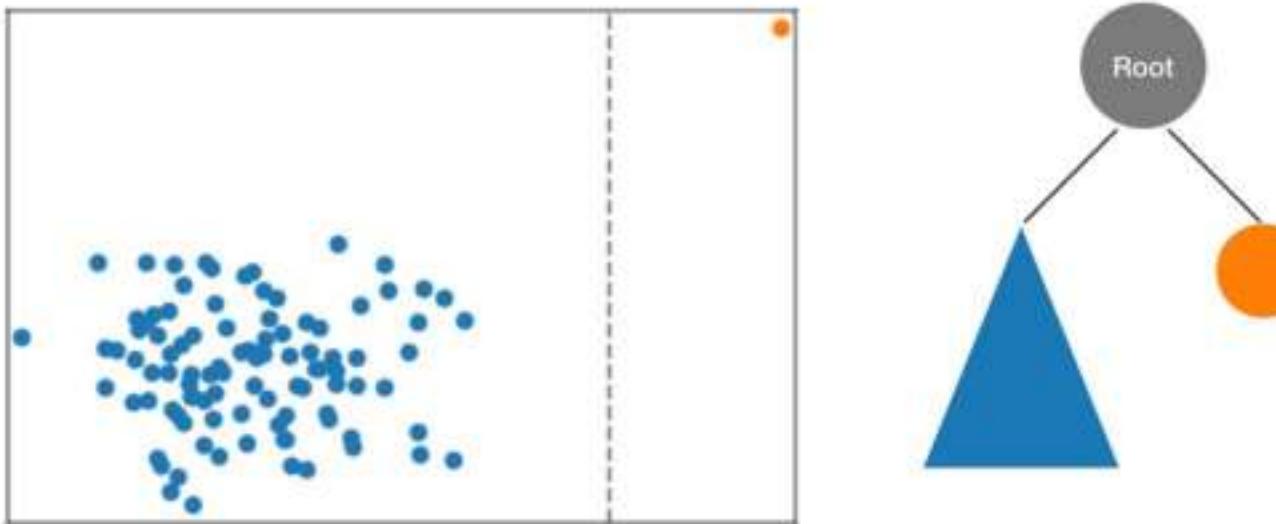

The next step in RCF is to construct a random cut forest using the random sample of data. First, the sample is partitioned into a number of equal-sized partitions equal to the number of trees in the forest. Then, each partition is sent to an individual tree. The tree recursively organizes its partition into a binary tree by partitioning the data domain into bounding boxes.

This procedure is best illustrated with an example. Suppose a tree is given the following two-dimensional dataset. The corresponding tree is initialized to the root node:

A two-dimensional dataset where the majority of data lies in a cluster (blue) except for one anomalous data point (orange). The tree is initialized with a root node.

The RCF algorithm organizes these data in a tree by first computing a bounding box of the data, selecting a random dimension (giving more weight to dimensions with higher "variance"), and then randomly determining the position of a hyperplane "cut" through that dimension. The two resulting subspaces define their own sub tree. In this example, the cut happens to separate a lone point from the remainder of the sample. The first level of the resulting binary tree consists of two nodes, one which will consist of the subtree of points to the left of the initial cut and the other representing the single point on the right.

A random cut partitioning the two-dimensional dataset. An anomalous data point is more likely to lie isolated in a bounding box at a smaller tree depth than other points.

Bounding boxes are then computed for the left and right halves of the data and the process is repeated until every leaf of the tree represents a single data point from the sample. Note that if the lone point is sufficiently far away then it is more likely that a random cut would result in point isolation. This observation provides the intuition that tree depth is, loosely speaking, inversely proportional to the anomaly score.

When performing inference using a trained RCF model the final anomaly score is reported as the average across scores reported by each tree. Note that it is often the case that the new data point does not already reside in the tree. To determine the score associated with the new point the data point is inserted into the given tree and the tree is efficiently (and temporarily) reassembled in a manner equivalent to the training process described above. That is, the resulting tree is as if the input data point were a member of the sample used to construct the tree in the first place. The reported score is inversely proportional to the depth of the input point within the tree.

### Choose Hyperparameters

The primary hyperparameters used to tune the RCF model are `num_trees` and `num_samples_per_tree`. Increasing `num_trees` has the effect of reducing the noise observed in anomaly scores since the final score is the average of the scores reported by each tree. While the optimal value is application-dependent we recommend using 100 trees to begin with as a balance between score noise and model complexity. Note that inference time is proportional to the number of trees. Although training time is also affected it is dominated by the reservoir sampling algorithm describe above.

The parameter `num_samples_per_tree` is related to the expected density of anomalies in the dataset. In particular, `num_samples_per_tree` should be chosen such that  $1/\text{num\_samples\_per\_tree}$  approximates the ratio of anomalous data to normal data. For example, if 256 samples are used in each tree then we expect our data to contain anomalies  $1/256$  or approximately 0.4% of the time. Again, an optimal value for this hyperparameter is dependent on the application.

## RCF Hyperparameters

In the [CreateTrainingJob](#) request, you specify the training algorithm. You can also specify algorithm-specific hyperparameters as string-to-string maps. The following table lists the hyperparameters for the Amazon SageMaker RCF algorithm. For more information, including recommendations on how to choose hyperparameters, see [How RCF Works \(p. 1496\)](#).

Parameter Name	Description
<code>feature_dim</code>	<p>The number of features in the data set. (If you use the <a href="#">Random Cut Forest</a> estimator, this value is calculated for you and need not be specified.)</p> <p><b>Required</b></p> <p>Valid values: Positive integer (min: 1, max: 10000)</p>
<code>eval_metrics</code>	<p>A list of metrics used to score a labeled test data set. The following metrics can be selected for output:</p> <ul style="list-style-type: none"> <li><code>accuracy</code> - returns fraction of correct predictions.</li> <li><code>precision_recall_fscore</code> - returns the positive and negative precision, recall, and F1-scores.</li> </ul> <p><b>Optional</b></p> <p>Valid values: a list with possible values taken from <code>accuracy</code> or <code>precision_recall_fscore</code>.</p> <p>Default value: Both <code>accuracy</code>, <code>precision_recall_fscore</code> are calculated.</p>
<code>num_samples_per_tree</code>	<p>Number of random samples given to each tree from the training data set.</p> <p><b>Optional</b></p> <p>Valid values: Positive integer (min: 1, max: 2048)</p> <p>Default value: 256</p>
<code>num_trees</code>	<p>Number of trees in the forest.</p> <p><b>Optional</b></p> <p>Valid values: Positive integer (min: 50, max: 1000)</p> <p>Default value: 100</p>

## Tune an RCF Model

*Automatic model tuning*, also known as hyperparameter tuning or hyperparameter optimization, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset.

You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

The Amazon SageMaker RCF algorithm is an unsupervised anomaly-detection algorithm that requires a labeled test dataset for hyperparameter optimization. RCF calculates anomaly scores for test datapoints and then labels the datapoints as anomalous if their scores are beyond three standard deviations from the mean score. This is known as the three-sigma limit heuristic. The F1-score is based on the difference between calculated labels and actual labels. The hyperparameter tuning job finds the model that maximizes that score. The success of hyperparameter optimization depends on the applicability of the three-sigma limit heuristic to the test dataset.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker \(p. 1745\)](#).

### Metrics Computed by the RCF Algorithm

The RCF algorithm computes the following metric during training. When tuning the model, choose this metric as the objective metric.

Metric Name	Description	Optimization Direction
test:f1	F1-score on the test dataset, based on the difference between calculated labels and actual labels.	Maximize

### Tunable RCF Hyperparameters

You can tune a RCF model with the following hyperparameters.

Parameter Name	Parameter Type	Recommended Ranges
num_samples_per_tree	IntegerParameterRanges	MinValue: 1, MaxValue:2048
num_trees	IntegerParameterRanges	MinValue: 50, MaxValue:1000

### RCF Response Formats

All Amazon SageMaker built-in algorithms adhere to the common input inference format described in [Common Data Formats - Inference](#). Note that SageMaker Random Cut Forest supports both dense and sparse JSON and RecordIO formats. This topic contains a list of the available output formats for the SageMaker RCF algorithm.

#### JSON Response Format

ACCEPT: application/json.

```
{
```

```
"scores": [  
  
    {"score": 0.02},  
  
    {"score": 0.25}  
  
]  
  
}
```

### JSONLINES Response Format

ACCEPT: application/jsonlines.

```
{"score": 0.02},  
{"score": 0.25}
```

### RECORDIO Response Format

ACCEPT: application/x-recordio-protobuf.

```
[  
  
    Record = {  
  
        features = {},  
  
        label = {  
  
            'score': {  
  
                keys: [],  
  
                values: [0.25] # float32  
  
            }  
  
        }  
  
    }  
  
]
```

```
        },  
  
        Record = {  
  
            features = {},  
  
            label = {  
  
                'score': {  
  
                    keys: [],  
  
                    values: [0.23] # float32  
  
                }  
  
            }  
  
        }  
  
    ]
```

## Semantic Segmentation Algorithm

The SageMaker semantic segmentation algorithm provides a fine-grained, pixel-level approach to developing computer vision applications. It tags every pixel in an image with a class label from a predefined set of classes. Tagging is fundamental for understanding scenes, which is critical to an increasing number of computer vision applications, such as self-driving vehicles, medical imaging diagnostics, and robot sensing.

For comparison, the SageMaker [Image Classification Algorithm \(p. 1399\)](#) is a supervised learning algorithm that analyzes only whole images, classifying them into one of multiple output categories. The [Object Detection Algorithm \(p. 1479\)](#) is a supervised learning algorithm that detects and classifies all instances of an object in an image. It indicates the location and scale of each object in the image with a rectangular bounding box.

Because the semantic segmentation algorithm classifies every pixel in an image, it also provides information about the shapes of the objects contained in the image. The segmentation output is represented as a grayscale image, called a *segmentation mask*. A segmentation mask is a grayscale image with the same shape as the input image.

The SageMaker semantic segmentation algorithm is built using the [MXNet Gluon framework](#) and the [Gluon CV toolkit](#), and provides you with a choice of three build-in algorithms to train a deep neural network. You can use the [Fully-Convolutional Network \(FCN\) algorithm](#), [Pyramid Scene Parsing \(PSP\) algorithm](#), or [DeepLabV3](#).

Each of the three algorithms has two distinct components:

- The *backbone* (or *encoder*)—A network that produces reliable activation maps of features.
- The *decoder*—A network that constructs the segmentation mask from the encoded activation maps.

You also have a choice of backbones for the FCN, PSP, and DeepLabV3 algorithms: [ResNet50](#) or [ResNet101](#). These backbones include pretrained artifacts that were originally trained on the [ImageNet](#) classification task. You can fine-tune these backbones for segmentation using your own data. Or, you can initialize and train these networks from scratch using only your own data. The decoders are never pretrained.

To deploy the trained model for inference, use the SageMaker hosting service. During inference, you can request the segmentation mask either as a PNG image or as a set of probabilities for each class for each pixel. You can use these masks as part of a larger pipeline that includes additional downstream image processing or other applications.

## Semantic Segmentation Sample Notebooks

For a sample Jupyter notebook that uses the SageMaker semantic segmentation algorithm to train a model and deploy it to perform inferences, see the [Semantic Segmentation Example](#). For instructions on how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see [Use Amazon SageMaker Notebook Instances \(p. 120\)](#).

To see a list of all of the SageMaker samples, create and open a notebook instance, and choose the [SageMaker Examples](#) tab. The example semantic segmentation notebooks are located under [Introduction to Amazon algorithms](#). To open a notebook, choose its **Use** tab, and choose **Create copy**.

## [Input/Output Interface for the Semantic Segmentation Algorithm](#)

SageMaker semantic segmentation expects the customer's training dataset to be on [Amazon Simple Storage Service \(Amazon S3\)](#). Once trained, it produces the resulting model artifacts on Amazon S3. The input interface format for the SageMaker semantic segmentation is similar to that of most standardized semantic segmentation benchmarking datasets. The dataset in Amazon S3 is expected to be presented in two channels, one for `train` and one for `validation` using four directories, two for images and two for annotations. Annotations are expected to be uncompressed PNG images. The dataset might also have a label map that describes how the annotation mappings are established. If not, the algorithm uses a default. It also supports the augmented manifest image format (`application/x-image`) for training in Pipe input mode straight from Amazon S3. For inference, an endpoint accepts images with an `image/jpg` content type.

### How Training Works

The training data is split into four directories: `train`, `train_annotation`, `validation`, and `validation_annotation`. There is a channel for each of these directories. The dataset also expected

to have one `label_map.json` file per channel for `train_annotation` and `validation_annotation` respectively. If you don't provide these JSON files, SageMaker provides the default set label map.

The dataset specifying these files should look similar to the following example:

```
s3://bucket_name
|
|- train
  |
  |- 0000.jpg
  |- coffee.jpg
|- validation
  |
  |- 00a0.jpg
  |- bananna.jpg
|- train_annotation
  |
  |- 0000.png
  |- coffee.png
|- validation_annotation
  |
  |- 00a0.png
  |- bananna.png
|- label_map
  |
  |- train_label_map.json
  |- validation_label_map.json
```

Every JPG image in the `train` and `validation` directories has a corresponding PNG label image with the same name in the `train_annotation` and `validation_annotation` directories. This naming convention helps the algorithm to associate a label with its corresponding image during training. The `train`, `train_annotation`, `validation`, and `validation_annotation` channels are mandatory. The annotations are single-channel PNG images. The format works as long as the metadata (modes) in the image helps the algorithm read the annotation images into a single-channel 8-bit unsigned integer. For more information on our support for modes, see the [Python Image Library documentation](#). We recommend using the 8-bit pixel, true color `P` mode.

The image that is encoded is a simple 8-bit integer when using modes. To get from this mapping to a map of a label, the algorithm uses one mapping file per channel, called the *label map*. The label map is used to map the values in the image with actual label indices. In the default label map, which is provided by default if you don't provide one, the pixel value in an annotation matrix (image) directly index the label. These images can be grayscale PNG files or 8-bit indexed PNG files. The label map file for the unscaled default case is the following:

```
{
  "scale": "1"
}
```

To provide some contrast for viewing, some annotation software scales the label images by a constant amount. To support this, the SageMaker semantic segmentation algorithm provides a rescaling option to scale down the values to actual label values. When scaling down doesn't convert the value to an appropriate integer, the algorithm defaults to the greatest integer less than or equal to the scale value. The following code shows how to set the scale value to rescale the label values:

```
{
  "scale": "3"
}
```

The following example shows how this `"scale"` value is used to rescale the `encoded_label` values of the input annotation image when they are mapped to the `mapped_label` values to be used in training.

The label values in the input annotation image are 0, 3, 6, with scale 3, so they are mapped to 0, 1, 2 for training:

```
encoded_label = [0, 3, 6]
mapped_label = [0, 1, 2]
```

In some cases, you might need to specify a particular color mapping for each class. Use the map option in the label mapping as shown in the following example of a `label_map` file:

```
{
  "map": {
    "0": 5,
    "1": 0,
    "2": 2
  }
}
```

This label mapping for this example is:

```
encoded_label = [0, 5, 2]
mapped_label = [1, 0, 2]
```

With label mappings, you can use different annotation systems and annotation software to obtain data without a lot of preprocessing. You can provide one label map per channel. The files for a label map in the `label_map` channel must follow the naming conventions for the four directory structure. If you don't provide a label map, the algorithm assumes a scale of 1 (the default).

### Training with the Augmented Manifest Format

The augmented manifest format enables you to do training in Pipe mode using image files without needing to create RecordIO files. The augmented manifest file contains data objects and should be in [JSON Lines](#) format, as described in the [CreateTrainingJob](#) request. Each line in the manifest is an entry containing the Amazon S3 URI for the image and the URI for the annotation image.

Each JSON object in the manifest file must contain a `source-ref` key. The `source-ref` key should contain the value of the Amazon S3 URI to the image. The labels are provided under the `AttributeNames` parameter value as specified in the [CreateTrainingJob](#) request. It can also contain additional metadata under the `metadata` tag, but these are ignored by the algorithm. In the example below, the `AttributeNames` are contained in the list of image and annotation references `[ "source-ref", "city-streets-ref" ]`. These names must have `-ref` appended to them. When using the Semantic Segmentation algorithm with Augmented Manifest, the value of the `RecordWrapperType` parameter must be `"RecordIO"` and value of the `ContentType` parameter must be `application/x-recordio`.

```
{"source-ref": "S3 bucket location", "city-streets-ref": "S3 bucket location", "city-streets-metadata": {"job-name": "label-city-streets", }}
```

For more information on augmented manifest files, see [Provide Dataset Metadata to Training Jobs with an Augmented Manifest File \(p. 1864\)](#).

### Incremental Training

You can also seed the training of a new model with a model that you trained previously using SageMaker. This incremental training saves training time when you want to train a new model with the same or similar data. Currently, incremental training is supported only for models trained with the built-in SageMaker Semantic Segmentation.

To use your own pre-trained model, specify the `ChannelName` as "model" in the `InputDataConfig` for the [CreateTrainingJob](#) request. Set the `ContentType` for the model channel to `application/x-sagemaker-model`. The `backbone`, `algorithm`, `crop_size`, and `num_classes` input parameters that define the network architecture must be consistently specified in the input hyperparameters of the new model and the pre-trained model that you upload to the model channel. For the pretrained model file, you can use the compressed (.tar.gz) artifacts from SageMaker outputs. You can only use Image formats for input data. For more information on incremental training and for instructions on how to use it, see [Incremental Training in Amazon SageMaker \(p. 1855\)](#).

### Produce Inferences

To query a trained model that is deployed to an endpoint, you need to provide an image and an `AcceptType` that denotes the type of output required. The endpoint takes JPEG images with an `image/jpeg` content type. If you request an `AcceptType` of `image/png`, the algorithm outputs a PNG file with a segmentation mask in the same format as the labels themselves. If you request an accept type of `application/x-recordio-protobuf`, the algorithm returns class probabilities encoded in recordio-protobuf format. The latter format outputs a 3D tensor where the third dimension is the same size as the number of classes. This component denotes the probability of each class label for each pixel.

## EC2 Instance Recommendation for the Semantic Segmentation Algorithm

The SageMaker semantic segmentation algorithm only supports GPU instances for training, and we recommend using GPU instances with more memory for training with large batch sizes. The algorithm can be trained using [P2/P3 EC2 Amazon Elastic Compute Cloud \(Amazon EC2\)](#) instances in single machine configurations. It supports the following GPU instances for training:

- `ml.p2.xlarge`
- `ml.p2.8xlarge`
- `ml.p2.16xlarge`
- `ml.p3.2xlarge`
- `ml.p3.8xlarge`
- `ml.p3.16xlarge`

For inference, you can use either CPU instances (such as `c5` and `m5`) and GPU instances (such as `p2` and `p3`) or both. For information about the instance types that provide varying combinations of CPU, GPU, memory, and networking capacity for inference, see [Amazon SageMaker ML Instance Types](#).

### Semantic Segmentation Hyperparameters

The following tables list the hyperparameters supported by the Amazon SageMaker semantic segmentation algorithm for network architecture, data inputs, and training. You specify Semantic Segmentation for training in the `AlgorithmName` of the [CreateTrainingJob](#) request.

#### Network Architecture Hyperparameters

Parameter Name	Description
<code>backbone</code>	<p>The backbone to use for the algorithm's encoder component.</p> <p><b>Optional</b></p> <p>Valid values: <code>resnet-50</code>, <code>resnet-101</code></p> <p>Default value: <code>resnet-50</code></p>

Parameter Name	Description
use_pretrained_model	<p>Whether a pretrained model is to be used for the backbone.</p> <p><b>Optional</b></p> <p>Valid values: <code>True</code>, <code>False</code></p> <p>Default value: <code>True</code></p>
algorithm	<p>The algorithm to use for semantic segmentation.</p> <p><b>Optional</b></p> <p>Valid values:</p> <ul style="list-style-type: none"> <li>• <code>fcn</code>: <a href="#">Fully-Convolutional Network (FCN) algorithm</a></li> <li>• <code>psp</code>: <a href="#">Pyramid Scene Parsing (PSP) algorithm</a></li> <li>• <code>deeplab</code>: <a href="#">DeepLab V3 algorithm</a></li> </ul> <p>Default value: <code>fcn</code></p>

## Data Hyperparameters

Parameter Name	Description
num_classes	<p>The number of classes to segment.</p> <p><b>Required</b></p> <p>Valid values: <math>2 \leq</math> positive integer <math>\leq 254</math></p>
num_training_samples	<p>The number of samples in the training data. The algorithm uses this value to set up the learning rate scheduler.</p> <p><b>Required</b></p> <p>Valid values: positive integer</p>
base_size	<p>Defines how images are rescaled before cropping. Images are rescaled such that the long size length is set to <code>base_size</code> multiplied by a random number from 0.5 to 2.0, and the short size is computed to preserve the aspect ratio.</p> <p><b>Optional</b></p> <p>Valid values: positive integer <math>&gt; 16</math></p> <p>Default value: 520</p>
crop_size	<p>The image size for input during training. We randomly rescale the input image based on <code>base_size</code>, and then take a random square crop with side length equal to <code>crop_size</code>. The <code>crop_size</code> will be automatically rounded up to multiples of 8.</p> <p><b>Optional</b></p> <p>Valid values: positive integer <math>&gt; 16</math></p>

Parameter Name	Description
	Default value: 240

### Training Hyperparameters

Parameter Name	Description
early_stopping	<p>Whether to use early stopping logic during training.</p> <p><b>Optional</b></p> <p>Valid values: True, False</p> <p>Default value: False</p>
early_stopping_min_epochs	<p>The minimum number of epochs that must be run.</p> <p><b>Optional</b></p> <p>Valid values: integer</p> <p>Default value: 5</p>
early_stopping_patience	<p>The number of epochs that meet the tolerance for lower performance before the algorithm enforces an early stop.</p> <p><b>Optional</b></p> <p>Valid values: integer</p> <p>Default value: 4</p>
early_stopping_tolerance	<p>If the relative improvement of the score of the training job, the mIOU, is smaller than this value, early stopping considers the epoch as not improved. This is used only when <code>early_stopping = True</code>.</p> <p><b>Optional</b></p> <p>Valid values: <math>0 \leq \text{float} \leq 1</math></p> <p>Default value: 0.0</p>
epochs	<p>The number of epochs with which to train.</p> <p><b>Optional</b></p> <p>Valid values: positive integer</p> <p>Default value: 10</p>
gamma1	<p>The decay factor for the moving average of the squared gradient for <code>rmsprop</code>. Used only for <code>rmsprop</code>.</p> <p><b>Optional</b></p> <p>Valid values: <math>0 \leq \text{float} \leq 1</math></p> <p>Default value: 0.9</p>

Parameter Name	Description
gamma2	<p>The momentum factor for <code>rmsprop</code>.</p> <p><b>Optional</b></p> <p>Valid values: <math>0 \leq \text{float} \leq 1</math></p> <p>Default value: 0.9</p>
learning_rate	<p>The initial learning rate.</p> <p><b>Optional</b></p> <p>Valid values: <math>0 &lt; \text{float} \leq 1</math></p> <p>Default value: 0.001</p>
lr_scheduler	<p>The shape of the learning rate schedule that controls its decrease over time.</p> <p><b>Optional</b></p> <p>Valid values:</p> <ul style="list-style-type: none"> <li>• <code>step</code>: A stepwise decay, where the learning rate is reduced (multiplied) by the <code>lr_scheduler_factor</code> after epochs specified by <code>lr_scheduler_step</code>.</li> <li>• <code>poly</code>: A smooth decay using a polynomial function.</li> <li>• <code>cosine</code>: A smooth decay using a cosine function.</li> </ul> <p>Default value: <code>poly</code></p>
lr_scheduler_factor	<p>If <code>lr_scheduler</code> is set to <code>step</code>, the ratio by which to reduce (multipy) the <code>learning_rate</code> after each of the epochs specified by the <code>lr_scheduler_step</code>. Otherwise, ignored.</p> <p><b>Optional</b></p> <p>Valid values: <math>0 \leq \text{float} \leq 1</math></p> <p>Default value: 0.1</p>
lr_scheduler_step	<p>A comma delimited list of the epochs after which the <code>learning_rate</code> is reduced (multiplied) by an <code>lr_scheduler_factor</code>. For example, if the value is set to "10, 20", then the <code>learning_rate</code> is reduced by <code>lr_scheduler_factor</code> after the 10th epoch and again by this factor after 20th epoch.</p> <p><b>Conditionally Required</b> if <code>lr_scheduler</code> is set to <code>step</code>. Otherwise, ignored.</p> <p>Valid values: string</p> <p>Default value: (No default, as the value is required when used.)</p>

Parameter Name	Description
mini_batch_size	<p>The batch size for training. Using a large <code>mini_batch_size</code> usually results in faster training, but it might cause you to run out of memory. Memory usage is affected by the values of the <code>mini_batch_size</code> and <code>image_shape</code> parameters, and the backbone architecture.</p> <p><b>Optional</b></p> <p>Valid values: positive integer</p> <p>Default value: 16</p>
momentum	<p>The momentum for the <code>sgd</code> optimizer. When you use other optimizers, the semantic segmentation algorithm ignores this parameter.</p> <p><b>Optional</b></p> <p>Valid values: <math>0 &lt; \text{float} \leq 1</math></p> <p>Default value: 0.9</p>
optimizer	<p>The type of optimizer. For more information about an optimizer, choose the appropriate link:</p> <ul style="list-style-type: none"> <li>• <code>adam</code>: <a href="#">Adaptive momentum estimation</a></li> <li>• <code>adagrad</code>: <a href="#">Adaptive gradient descent</a></li> <li>• <code>nag</code>: <a href="#">Nesterov accelerated gradient</a></li> <li>• <code>rmsprop</code>: <a href="#">Root mean square propagation</a></li> <li>• <code>sgd</code>: <a href="#">Stochastic gradient descent</a></li> </ul> <p><b>Optional</b></p> <p>Valid values: <code>adam</code>, <code>adagrad</code>, <code>nag</code>, <code>rmsprop</code>, <code>sgd</code></p> <p>Default value: <code>sgd</code></p>
syncbn	<p>If set to <code>True</code>, the batch normalization mean and variance are computed over all the samples processed across the GPUs.</p> <p><b>Optional</b></p> <p>Valid values: <code>True</code>, <code>False</code></p> <p>Default value: <code>False</code></p>

Parameter Name	Description
validation_mini_batch	<p>The batch size for validation. A large <code>mini_batch_size</code> usually results in faster training, but it might cause you to run out of memory. Memory usage is affected by the values of the <code>mini_batch_size</code> and <code>image_shape</code> parameters, and the backbone architecture.</p> <ul style="list-style-type: none"> <li>To score the validation on the entire image without cropping the images, set this parameter to 1. Use this option if you want to measure performance on the entire image as a whole.</li> </ul> <p><b>Note</b> Setting the <code>validation_mini_batch_size</code> parameter to 1 causes the algorithm to create a new network model for every image. This might slow validation and training.</p> <ul style="list-style-type: none"> <li>To crop images to the size specified in the <code>crop_size</code> parameter, even during evaluation, set this parameter to a value greater than 1.</li> </ul> <p><b>Optional</b> Valid values: positive integer Default value: 16</p>
weight_decay	<p>The weight decay coefficient for the <code>sgd</code> optimizer. When you use other optimizers, the algorithm ignores this parameter.</p> <p><b>Optional</b> Valid values: <math>0 &lt; \text{float} &lt; 1</math> Default value: 0.0001</p>

## Tuning a Semantic Segmentation Model

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

### Metrics Computed by the Semantic Segmentation Algorithm

The semantic segmentation algorithm reports two validation metrics. When tuning hyperparameter values, choose one of these metrics as the objective.

Metric Name	Description	Optimization Direction
validation:mIOU	The area of the intersection of the predicted segmentation and the ground truth divided by the area of union between them for images in the validation set. Also known as the Jaccard Index.	Maximize
validation:pixel_accuracy	The percentage of pixels that are correctly classified in images from the validation set.	Maximize

## Tunable Semantic Segmentation Hyperparameters

You can tune the following hyperparameters for the semantic segmentation algorithm.

Parameter Name	Parameter Type	Recommended Ranges
learning_rate	ContinuousParameterRange	MinValue: 1e-4, MaxValue: 1e-1
mini_batch_size	IntegerParameterRanges	MinValue: 1, MaxValue: 128
momentum	ContinuousParameterRange	MinValue: 0.9, MaxValue: 0.999
optimzer	CategoricalParameterRanges	['sgd', 'adam', 'adadelta']
weight_decay	ContinuousParameterRange	MinValue: 1e-5, MaxValue: 1e-3

## Sequence-to-Sequence Algorithm

Amazon SageMaker Sequence to Sequence is a supervised learning algorithm where the input is a sequence of tokens (for example, text, audio) and the output generated is another sequence of tokens. Example applications include: machine translation (input a sentence from one language and predict what that sentence would be in another language), text summarization (input a longer string of words and predict a shorter string of words that is a summary), speech-to-text (audio clips converted into output sentences in tokens). Recently, problems in this domain have been successfully modeled with deep neural networks that show a significant performance boost over previous methodologies. Amazon SageMaker seq2seq uses Recurrent Neural Networks (RNNs) and Convolutional Neural Network (CNN) models with attention as encoder-decoder architectures.

## Input/Output Interface for the Sequence-to-Sequence Algorithm

### Training

SageMaker seq2seq expects data in RecordIO-Protobuf format. However, the tokens are expected as integers, not as floating points, as is usually the case.

A script to convert data from tokenized text files to the protobuf format is included in [the seq2seq example notebook](#). In general, it packs the data into 32-bit integer tensors and generates the necessary vocabulary files, which are needed for metric calculation and inference.

After preprocessing is done, the algorithm can be invoked for training. The algorithm expects three channels:

- **train:** It should contain the training data (for example, the `train.rec` file generated by the preprocessing script).

- validation: It should contain the validation data (for example, the `val.rec` file generated by the preprocessing script).
- vocab: It should contain two vocabulary files (`vocab.src.json` and `vocab.trg.json`)

If the algorithm doesn't find data in any of these three channels, training results in an error.

### Inference

For hosted endpoints, inference supports two data formats. To perform inference using space separated text tokens, use the `application/json` format. Otherwise, use the `recordio-protobuf` format to work with the integer encoded data. Both modes support batching of input data. `application/json` format also allows you to visualize the attention matrix.

- `application/json`: Expects the input in JSON format and returns the output in JSON format. Both content and accept types should be `application/json`. Each sequence is expected to be a string with whitespace separated tokens. This format is recommended when the number of source sequences in the batch is small. It also supports the following additional configuration options:

`configuration: {attention_matrix: true}`: Returns the attention matrix for the particular input sequence.

- `application/x-recordio-protobuf`: Expects the input in `recordio-protobuf` format and returns the output in `recordio-protobuf` format. Both content and accept types should be `applications/x-recordio-protobuf`. For this format, the source sequences must be converted into a list of integers for subsequent protobuf encoding. This format is recommended for bulk inference.

For batch transform, inference supports JSON Lines format. Batch transform expects the input in JSON Lines format and returns the output in JSON Lines format. Both content and accept types should be `application/jsonlines`. The format for input is as follows:

```
content-type: application/jsonlines

{"source": "source_sequence_0"}
{"source": "source_sequence_1"}
```

The format for response is as follows:

```
accept: application/jsonlines

{"target": "predicted_sequence_0"}
{"target": "predicted_sequence_1"}
```

For additional details on how to serialize and deserialize the inputs and outputs to specific formats for inference, see the [Sequence-to-Sequence Sample Notebooks \(p. 1513\)](#).

## EC2 Instance Recommendation for the Sequence-to-Sequence Algorithm

Currently Amazon SageMaker seq2seq is only supported on GPU instance types and is only set up to train on a single machine. But it does also offer support for multiple GPUs.

### Sequence-to-Sequence Sample Notebooks

For a sample notebook that shows how to use the SageMaker Sequence to Sequence algorithm to train a English-German translation model, see [Machine Translation English-German Example Using SageMaker Seq2Seq](#). For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see [Use Amazon SageMaker Notebook Instances \(p. 120\)](#). Once you have created a notebook instance and opened it, select the **SageMaker Examples** tab to see a list of all the

SageMaker samples. The topic modeling example notebooks using the NTM algorithms are located in the **Introduction to Amazon algorithms** section. To open a notebook, click on its **Use** tab and select **Create copy**.

## How Sequence-to-Sequence Works

Typically, a neural network for sequence-to-sequence modeling consists of a few layers, including:

- An **embedding layer**. In this layer, the input matrix, which is input tokens encoded in a sparse way (for example, one-hot encoded) are mapped to a dense feature layer. This is required because a high-dimensional feature vector is more capable of encoding information regarding a particular token (word for text corpora) than a simple one-hot-encoded vector. It is also a standard practice to initialize this embedding layer with a pre-trained word vector like [FastText](#) or [Glove](#) or to initialize it randomly and learn the parameters during training.
- An **encoder layer**. After the input tokens are mapped into a high-dimensional feature space, the sequence is passed through an encoder layer to compress all the information from the input embedding layer (of the entire sequence) into a fixed-length feature vector. Typically, an encoder is made of RNN-type networks like long short-term memory (LSTM) or gated recurrent units (GRU). ([Colah's blog](#) explains LSTM in a great detail.)
- A **decoder layer**. The decoder layer takes this encoded feature vector and produces the output sequence of tokens. This layer is also usually built with RNN architectures (LSTM and GRU).

The whole model is trained jointly to maximize the probability of the target sequence given the source sequence. This model was first introduced by [Sutskever et al.](#) in 2014.

**Attention mechanism.** The disadvantage of an encoder-decoder framework is that model performance decreases as and when the length of the source sequence increases because of the limit of how much information the fixed-length encoded feature vector can contain. To tackle this problem, in 2015, Bahdanau et al. proposed the [attention mechanism](#). In an attention mechanism, the decoder tries to find the location in the encoder sequence where the most important information could be located and uses that information and previously decoded words to predict the next token in the sequence.

For more in details, see the whitepaper [Effective Approaches to Attention-based Neural Machine Translation](#) by Luong, et al. that explains and simplifies calculations for various attention mechanisms. Additionally, the whitepaper [Google's Neural Machine Translation System: Bridging the Gap between Human and Machine Translation](#) by Wu, et al. describes Google's architecture for machine translation, which uses skip connections between encoder and decoder layers.

## Sequence-to-Sequence Hyperparameters

Parameter Name	Description
<code>batch_size</code>	<p>Mini batch size for gradient descent.</p> <p><b>Optional</b></p> <p>Valid values: positive integer</p> <p>Default value: 64</p>
<code>beam_size</code>	<p>Length of the beam for beam search. Used during training for computing <code>bleu</code> and used during inference.</p> <p><b>Optional</b></p> <p>Valid values: positive integer</p> <p>Default value: 5</p>

Parameter Name	Description
bleu_sample_size	<p>Number of instances to pick from validation dataset to decode and compute bleu score during training. Set to -1 to use full validation set (if bleu is chosen as optimized_metric).</p> <p><b>Optional</b></p> <p>Valid values: integer</p> <p>Default value: 0</p>
bucket_width	<p>Returns (source,target) buckets up to (max_seq_len_source,max_seq_len_target). The longer side of the data uses steps of bucket_width while the shorter side uses steps scaled down by the average target/source length ratio. If one sided reaches its maximum length before the other, width of extra buckets on that side is fixed to that side of max_len.</p> <p><b>Optional</b></p> <p>Valid values: positive integer</p> <p>Default value: 10</p>
bucketing_enabled	<p>Set to false to disable bucketing, unroll to maximum length.</p> <p><b>Optional</b></p> <p>Valid values: true or false</p> <p>Default value: true</p>
checkpoint_frequency_num_batches	<p>Checkpoint and evaluate every x batches. This checkpointing hyperparameter is passed to the SageMaker's seq2seq algorithm for early stopping and retrieving the best model. The algorithm's checkpointing runs locally in the algorithm's training container and is not compatible with SageMaker checkpointing. The algorithm temporarily saves checkpoints to a local path and stores the best model artifact to the model output path in S3 after the training job has stopped.</p> <p><b>Optional</b></p> <p>Valid values: positive integer</p> <p>Default value: 1000</p>

Parameter Name	Description
<code>checkpoint_threshold</code>	<p>Maximum number of checkpoints model is allowed to not improve in <code>optimized_metric</code> on validation dataset before training is stopped. This checkpointing hyperparameter is passed to the SageMaker's seq2seq algorithm for early stopping and retrieving the best model. The algorithm's checkpointing runs locally in the algorithm's training container and is not compatible with SageMaker checkpointing. The algorithm temporarily saves checkpoints to a local path and stores the best model artifact to the model output path in S3 after the training job has stopped.</p> <p><b>Optional</b></p> <p>Valid values: positive integer</p> <p>Default value: 3</p>
<code>clip_gradient</code>	<p>Clip absolute gradient values greater than this. Set to negative to disable.</p> <p><b>Optional</b></p> <p>Valid values: float</p> <p>Default value: 1</p>
<code>cnn_activation_type</code>	<p>The <code>cnn</code> activation type to be used.</p> <p><b>Optional</b></p> <p>Valid values: String. One of <code>glu</code>, <code>relu</code>, <code>softrelu</code>, <code>sigmoid</code>, or <code>tanh</code>.</p> <p>Default value: <code>glu</code></p>
<code>cnn_hidden_dropout</code>	<p>Dropout probability for dropout between convolutional layers.</p> <p><b>Optional</b></p> <p>Valid values: Float. Range in [0,1].</p> <p>Default value: 0</p>
<code>cnn_kernel_width_decoder</code>	<p>Kernel width for the <code>cnn</code> decoder.</p> <p><b>Optional</b></p> <p>Valid values: positive integer</p> <p>Default value: 5</p>

Parameter Name	Description
cnn_kernel_width_encoder	<p>Kernel width for the <code>cnn</code> encoder.</p> <p><b>Optional</b></p> <p>Valid values: positive integer</p> <p>Default value: 3</p>
cnn_num_hidden	<p>Number of <code>cnn</code> hidden units for encoder and decoder.</p> <p><b>Optional</b></p> <p>Valid values: positive integer</p> <p>Default value: 512</p>
decoder_type	<p>Decoder type.</p> <p><b>Optional</b></p> <p>Valid values: String. Either <code>rnn</code> or <code>cnn</code>.</p> <p>Default value: <code>rnn</code></p>
embed_dropout_source	<p>Dropout probability for source side embeddings.</p> <p><b>Optional</b></p> <p>Valid values: Float. Range in [0,1].</p> <p>Default value: 0</p>
embed_dropout_target	<p>Dropout probability for target side embeddings.</p> <p><b>Optional</b></p> <p>Valid values: Float. Range in [0,1].</p> <p>Default value: 0</p>
encoder_type	<p>Encoder type. The <code>rnn</code> architecture is based on attention mechanism by Bahdanau et al. and <code>cnn</code> architecture is based on Gehring et al.</p> <p><b>Optional</b></p> <p>Valid values: String. Either <code>rnn</code> or <code>cnn</code>.</p> <p>Default value: <code>rnn</code></p>
fixed_rate_lr_half_life	<p>Half life for learning rate in terms of number of checkpoints for <code>fixed_rate_*</code> schedulers.</p> <p><b>Optional</b></p> <p>Valid values: positive integer</p> <p>Default value: 10</p>

Parameter Name	Description
<code>learning_rate</code>	<p>Initial learning rate.</p> <p><b>Optional</b></p> <p>Valid values: float</p> <p>Default value: 0.0003</p>
<code>loss_type</code>	<p>Loss function for training.</p> <p><b>Optional</b></p> <p>Valid values: String. <code>cross-entropy</code></p> <p>Default value: <code>cross-entropy</code></p>
<code>lr_scheduler_type</code>	<p>Learning rate scheduler type. <code>plateau_reduce</code> means reduce the learning rate whenever <code>optimized_metric</code> on <code>validation_accuracy</code> plateaus. <code>inv_t</code> is inverse time decay. <math>\text{learning\_rate}/(1+\text{decay\_rate}^t)</math></p> <p><b>Optional</b></p> <p>Valid values: String. One of <code>plateau_reduce</code>, <code>fixed_rate_inv_t</code>, or <code>fixed_rate_inv_sqrt_t</code>.</p> <p>Default value: <code>plateau_reduce</code></p>
<code>max_num_batches</code>	<p>Maximum number of updates/batches to process. -1 for infinite.</p> <p><b>Optional</b></p> <p>Valid values: integer</p> <p>Default value: -1</p>
<code>max_num_epochs</code>	<p>Maximum number of epochs to pass through training data before fitting is stopped. Training continues until this number of epochs even if validation accuracy is not improving if this parameter is passed. Ignored if not passed.</p> <p><b>Optional</b></p> <p>Valid values: Positive integer and less than or equal to <code>max_num_epochs</code>.</p> <p>Default value: none</p>
<code>max_seq_len_source</code>	<p>Maximum length for the source sequence length. Sequences longer than this length are truncated to this length.</p> <p><b>Optional</b></p> <p>Valid values: positive integer</p> <p>Default value: 100</p>

Parameter Name	Description
max_seq_len_target	<p>Maximum length for the target sequence length. Sequences longer than this length are truncated to this length.</p> <p><b>Optional</b></p> <p>Valid values: positive integer</p> <p>Default value: 100</p>
min_num_epochs	<p>Minimum number of epochs the training must run before it is stopped via <code>early_stopping</code> conditions.</p> <p><b>Optional</b></p> <p>Valid values: positive integer</p> <p>Default value: 0</p>
momentum	<p>Momentum constant used for <code>sgd</code>. Don't pass this parameter if you are using <code>adam</code> or <code>rmsprop</code>.</p> <p><b>Optional</b></p> <p>Valid values: float</p> <p>Default value: none</p>
num_embed_source	<p>Embedding size for source tokens.</p> <p><b>Optional</b></p> <p>Valid values: positive integer</p> <p>Default value: 512</p>
num_embed_target	<p>Embedding size for target tokens.</p> <p><b>Optional</b></p> <p>Valid values: positive integer</p> <p>Default value: 512</p>
num_layers_decoder	<p>Number of layers for Decoder <code>rnn</code> or <code>cnn</code>.</p> <p><b>Optional</b></p> <p>Valid values: positive integer</p> <p>Default value: 1</p>
num_layers_encoder	<p>Number of layers for Encoder <code>rnn</code> or <code>cnn</code>.</p> <p><b>Optional</b></p> <p>Valid values: positive integer</p> <p>Default value: 1</p>

Parameter Name	Description
optimized_metric	<p>Metrics to optimize with early stopping.</p> <p><b>Optional</b></p> <p>Valid values: String. One of <code>perplexity</code>, <code>accuracy</code>, or <code>bleu</code>.</p> <p>Default value: <code>perplexity</code></p>
optimizer_type	<p>Optimizer to choose from.</p> <p><b>Optional</b></p> <p>Valid values: String. One of <code>adam</code>, <code>sgd</code>, or <code>rmsprop</code>.</p> <p>Default value: <code>adam</code></p>
plateau_reduce_lr_factor	<p>Factor to multiply learning rate with (for <code>plateau_reduce</code>).</p> <p><b>Optional</b></p> <p>Valid values: float</p> <p>Default value: 0.5</p>
plateau_reduce_lr_threshold	<p>For <code>plateau_reduce</code> scheduler, multiply learning rate with reduce factor if <code>optimized_metric</code> didn't improve for this many checkpoints.</p> <p><b>Optional</b></p> <p>Valid values: positive integer</p> <p>Default value: 3</p>
rnn_attention_in_upper_layers	<p>Pass the attention to upper layers of <code>rnn</code>, like Google NMT paper. Only applicable if more than one layer is used.</p> <p><b>Optional</b></p> <p>Valid values: boolean (<code>true</code> or <code>false</code>)</p> <p>Default value: <code>true</code></p>
rnn_attention_num_hidden	<p>Number of hidden units for attention layers. defaults to <code>rnn_num_hidden</code>.</p> <p><b>Optional</b></p> <p>Valid values: positive integer</p> <p>Default value: <code>rnn_num_hidden</code></p>

Parameter Name	Description
rnn_attention_type	<p>Attention model for encoders. <code>mlp</code> refers to concat and bilinear refers to general from the Luong et al. paper.</p> <p><b>Optional</b></p> <p>Valid values: String. One of <code>dot</code>, <code>fixed</code>, <code>mlp</code>, or <code>bilinear</code>.</p> <p>Default value: <code>mlp</code></p>
rnn_cell_type	<p>Specific type of <code>rnn</code> architecture.</p> <p><b>Optional</b></p> <p>Valid values: String. Either <code>lstm</code> or <code>gru</code>.</p> <p>Default value: <code>lstm</code></p>
rnn_decoder_state_init	<p>How to initialize <code>rnn</code> decoder states from encoders.</p> <p><b>Optional</b></p> <p>Valid values: String. One of <code>last</code>, <code>avg</code>, or <code>zero</code>.</p> <p>Default value: <code>last</code></p>
rnn_first_residual_layer	<p>First <code>rnn</code> layer to have a residual connection, only applicable if number of layers in encoder or decoder is more than 1.</p> <p><b>Optional</b></p> <p>Valid values: positive integer</p> <p>Default value: 2</p>
rnn_num_hidden	<p>The number of <code>rnn</code> hidden units for encoder and decoder. This must be a multiple of 2 because the algorithm uses bi-directional Long Term Short Term Memory (LSTM) by default.</p> <p><b>Optional</b></p> <p>Valid values: positive even integer</p> <p>Default value: 1024</p>
rnn_residual_connections	<p>Add residual connection to stacked <code>rnn</code>. Number of layers should be more than 1.</p> <p><b>Optional</b></p> <p>Valid values: boolean (<code>true</code> or <code>false</code>)</p> <p>Default value: <code>false</code></p>

Parameter Name	Description
<code>rnn_decoder_hidden_dropout</code>	<p>Dropout probability for hidden state that combines the context with the <i>rnn</i> hidden state in the decoder.</p> <p><b>Optional</b></p> <p>Valid values: Float. Range in [0,1].</p> <p>Default value: 0</p>
<code>training_metric</code>	<p>Metrics to track on training on validation data.</p> <p><b>Optional</b></p> <p>Valid values: String. Either <code>perplexity</code> or <code>accuracy</code>.</p> <p>Default value: <code>perplexity</code></p>
<code>weight_decay</code>	<p>Weight decay constant.</p> <p><b>Optional</b></p> <p>Valid values: float</p> <p>Default value: 0</p>
<code>weight_init_scale</code>	<p>Weight initialization scale (for <code>uniform</code> and <code>xavier</code> initialization).</p> <p><b>Optional</b></p> <p>Valid values: float</p> <p>Default value: 2.34</p>
<code>weight_init_type</code>	<p>Type of weight initialization.</p> <p><b>Optional</b></p> <p>Valid values: String. Either <code>uniform</code> or <code>xavier</code>.</p> <p>Default value: <code>xavier</code></p>
<code>xavier_factor_type</code>	<p>Xavier factor type.</p> <p><b>Optional</b></p> <p>Valid values: String. One of <code>in</code>, <code>out</code>, or <code>avg</code>.</p> <p>Default value: <code>in</code></p>

## Tune a Sequence-to-Sequence Model

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker \(p. 1745\)](#).

### Metrics Computed by the Sequence-to-Sequence Algorithm

The sequence to sequence algorithm reports three metrics that are computed during training. Choose one of them as an objective to optimize when tuning the hyperparameter values.

Metric Name	Description	Optimization Direction
validation:accuracy	Accuracy computed on the validation dataset.	Maximize
validation:bleu	Bleu score computed on the validation dataset. Because BLEU computation is expensive, you can choose to compute BLEU on a random subsample of the validation dataset to speed up the overall training process. Use the <code>bleu_sample_size</code> parameter to specify the subsample.	Maximize
validation:perplexity	Perplexity, is a loss function computed on the validation dataset. Perplexity measures the cross-entropy between an empirical sample and the distribution predicted by a model and so provides a measure of how well a model predicts the sample values, Models that are good at predicting a sample have a low perplexity.	Minimize

### Tunable Sequence-to-Sequence Hyperparameters

You can tune the following hyperparameters for the SageMaker Sequence to Sequence algorithm. The hyperparameters that have the greatest impact on sequence to sequence objective metrics are: `batch_size`, `optimizer_type`, `learning_rate`, `num_layers_encoder`, and `num_layers_decoder`.

Parameter Name	Parameter Type	Recommended Ranges
<code>num_layers_encoder</code>	IntegerParameterRange	[1-10]
<code>num_layers_decoder</code>	IntegerParameterRange	[1-10]
<code>batch_size</code>	CategoricalParameterRange	[16,32,64,128,256,512,1024,2048]
<code>optimizer_type</code>	CategoricalParameterRange	['adam', 'sgd', 'rmsprop']
<code>weight_init_type</code>	CategoricalParameterRange	['xavier', 'uniform']
<code>weight_init_scale</code>	ContinuousParameterRange	For the xavier type: MinValue: 2.0, MaxValue: 3.0 For the uniform type: MinValue: -1.0, MaxValue: 1.0
<code>learning_rate</code>	ContinuousParameterRange	MinValue: 0.00005, MaxValue: 0.2
<code>weight_decay</code>	ContinuousParameterRange	MinValue: 0.0, MaxValue: 0.1

Parameter Name	Parameter Type	Recommended Ranges
momentum	ContinuousParameterRange	MinValue: 0.5, MaxValue: 0.9
clip_gradient	ContinuousParameterRange	MinValue: 1.0, MaxValue: 5.0
rnn_num_hidden	CategoricalParameterRange	Applicable only to recurrent neural networks (RNNs). [128,256,512,1024,2048]
cnn_num_hidden	CategoricalParameterRange	Applicable only to convolutional neural networks (CNNs). [128,256,512,1024,2048]
num_embed_source	IntegerParameterRange	[256-512]
num_embed_target	IntegerParameterRange	[256-512]
embed_dropout_source	ContinuousParameterRange	MinValue: 0.0, MaxValue: 0.5
embed_dropout_target	ContinuousParameterRange	MinValue: 0.0, MaxValue: 0.5
rnn_decoder_hidden_dropout	ContinuousParameterRange	MinValue: 0.0, MaxValue: 0.5
cnn_hidden_dropout	ContinuousParameterRange	MinValue: 0.0, MaxValue: 0.5
lr_scheduler_type	CategoricalParameterRange	['plateau_reduce', 'fixed_rate_inv_t', 'fixed_rate_inv_sqrt_t']
plateau_reduce_lr_factor	ContinuousParameterRange	MinValue: 0.1, MaxValue: 0.5
plateau_reduce_lr_threshold	IntegerParameterRange	[1-5]
fixed_rate_lr_half_life	IntegerParameterRange	[10-30]

## XGBoost Algorithm

The [XGBoost](#) (eXtreme Gradient Boosting) is a popular and efficient open-source implementation of the gradient boosted trees algorithm. Gradient boosting is a supervised learning algorithm that attempts to accurately predict a target variable by combining an ensemble of estimates from a set of simpler and weaker models. The XGBoost algorithm performs well in machine learning competitions because of its robust handling of a variety of data types, relationships, distributions, and the variety of hyperparameters that you can fine-tune. You can use XGBoost for regression, classification (binary and multiclass), and ranking problems.

You can use the new release of the XGBoost algorithm either as a Amazon SageMaker built-in algorithm or as a framework to run training scripts in your local environments. This implementation has a smaller memory footprint, better logging, improved hyperparameter validation, and an expanded set of metrics than the original versions. It provides an XGBoost estimator that executes a training script in a

managed XGBoost environment. The current release of SageMaker XGBoost is based on the original XGBoost versions 0.90, 1.0, and 1.2.

## Supported versions

- Framework (open source) mode: 0.90-1, 0.90-2, 1.0-1, 1.2-1, 1.2-2, 1.3-1
- Algorithm mode: 0.90-1, 0.90-2, 1.0-1, 1.2-1, 1.2-2, 1.3-1

### Note

XGBoost 1.1 is not supported on SageMaker because XGBoost 1.1 has a broken capability to run prediction when the test input has fewer features than the training data in LIBSVM inputs. This capability has been restored in XGBoost 1.2. Consider using SageMaker XGBoost 1.2-2 or later.

## How to Use SageMaker XGBoost

With SageMaker, you can use XGBoost as a built-in algorithm or framework. By using XGBoost as a framework, you have more flexibility and access to more advanced scenarios, such as k-fold cross-validation, because you can customize your own training scripts.

### • Use XGBoost as a framework

Use XGBoost as a framework to run your customized training scripts that can incorporate additional data processing into your training jobs. In the following code example, you can find how SageMaker Python SDK provides the XGBoost API as a framework in the same way it provides other framework APIs, such as TensorFlow, MXNet, and PyTorch.

SageMaker Python SDK v1

```
import boto3
import sagemaker
from sagemaker.xgboost.estimator import XGBoost
from sagemaker.session import s3_input, Session

# initialize hyperparameters
hyperparameters = {
    "max_depth": "5",
    "eta": "0.2",
    "gamma": "4",
    "min_child_weight": "6",
    "subsample": "0.7",
    "verbosity": "1",
    "objective": "reg:linear",
    "num_round": "50"}

# set an output path where the trained model will be saved
bucket = sagemaker.Session().default_bucket()
prefix = 'DEMO-xgboost-as-a-framework'
output_path = 's3://{}//{}//{}//{}//output'.format(bucket, prefix, 'abalone-xgb-framework')

# construct a SageMaker XGBoost estimator
# specify the entry_point to your xgboost training script
estimator = XGBoost(entry_point = "your_xgboost_abalone_script.py",
                    framework_version='1.2-2',
                    hyperparameters=hyperparameters,
                    role=sagemaker.get_execution_role(),
                    instance_count=1,
                    instance_type='ml.m5.2xlarge',
                    output_path=output_path)

# define the data type and paths to the training and validation datasets
content_type = "libsvm"
```

```

train_input = s3_input("s3://{}:{}{}".format(bucket, prefix, 'train'),
                      content_type=content_type)
validation_input = s3_input("s3://{}:{}{}".format(bucket, prefix, 'validation'),
                           content_type=content_type)

# execute the XGBoost training job
estimator.fit({'train': train_input, 'validation': validation_input})

```

### SageMaker Python SDK v2

```

import boto3
import sagemaker
from sagemaker.xgboost.estimator import XGBoost
from sagemaker.session import Session
from sagemaker.inputs import TrainingInput

# initialize hyperparameters
hyperparameters = {
    "max_depth": "5",
    "eta": "0.2",
    "gamma": "4",
    "min_child_weight": "6",
    "subsample": "0.7",
    "verbosity": "1",
    "objective": "reg:linear",
    "num_round": "50"}

# set an output path where the trained model will be saved
bucket = sagemaker.Session().default_bucket()
prefix = 'DEMO-xgboost-as-a-framework'
output_path = 's3://{}:{}{}/output'.format(bucket, prefix, 'abalone-xgb-framework')

# construct a SageMaker XGBoost estimator
# specify the entry_point to your xgboost training script
estimator = XGBoost(entry_point = "your_xgboost_abalone_script.py",
                     framework_version='1.2-2',
                     hyperparameters=hyperparameters,
                     role=sagemaker.get_execution_role(),
                     instance_count=1,
                     instance_type='ml.m5.2xlarge',
                     output_path=output_path)

# define the data type and paths to the training and validation datasets
content_type = "libsvm"
train_input = TrainingInput("s3://{}:{}{}".format(bucket, prefix, 'train'),
                           content_type=content_type)
validation_input = TrainingInput("s3://{}:{}{}".format(bucket, prefix,
                                                     'validation'), content_type=content_type)

# execute the XGBoost training job
estimator.fit({'train': train_input, 'validation': validation_input})

```

For an end-to-end example of using SageMaker XGBoost as a framework, see [Regression with Amazon SageMaker XGBoost](#)

- **Use XGBoost as a built-in algorithm**

Use the XGBoost built-in algorithm to build an XGBoost training container as shown in the following code example. You can automatically spot the XGBoost built-in algorithm image URI using the SageMaker `image_uris.retrieve` API (or the `get_image_uri` API if using [Amazon SageMaker Python SDK](#) version 1). If you want to ensure if the `image_uris.retrieve` API finds the correct URI, see [Common parameters for built-in algorithms](#) and look up `xgboost` from the full list of built-in algorithm image URIs and available regions.

After specifying the XGBoost image URI, you can use the XGBoost container to construct an estimator using the SageMaker Estimator API and initiate a training job. This XGBoost built-in algorithm mode does not incorporate your own XGBoost training script and runs directly on the input datasets.

#### SageMaker Python SDK v1

```

import sagemaker
import boto3
from sagemaker.amazon.amazon_estimator import get_image_uri
from sagemaker.session import s3_input, Session

# initialize hyperparameters
hyperparameters = {
    "max_depth": "5",
    "eta": "0.2",
    "gamma": "4",
    "min_child_weight": "6",
    "subsample": "0.7",
    "objective": "reg:squarederror",
    "num_round": "50"}

# set an output path where the trained model will be saved
bucket = sagemaker.Session().default_bucket()
prefix = 'DEMO-xgboost-as-a-built-in-algo'
output_path = 's3://{}//{}//{}//output'.format(bucket, prefix, 'abalone-xgb-built-in-algo')

# this line automatically looks for the XGBoost image URI and builds an XGBoost
# container.
# specify the repo_version depending on your preference.
xgboost_container = get_image_uri(boto3.Session().region_name,
                                   'xgboost',
                                   repo_version='1.2-2')

# construct a SageMaker estimator that calls the xgboost-container
estimator = sagemaker.estimator.Estimator(image_name=xgboost_container,
                                           hyperparameters=hyperparameters,
                                           role=sagemaker.get_execution_role(),
                                           instance_count=1,
                                           instance_type='ml.m5.2xlarge',
                                           train_volume_size=5, # 5 GB
                                           output_path=output_path)

# define the data type and paths to the training and validation datasets
content_type = "libsvm"
train_input = s3_input("s3://{}//{}//{}//".format(bucket, prefix, 'train'),
                      content_type=content_type)
validation_input = s3_input("s3://{}//{}//{}//".format(bucket, prefix, 'validation'),
                           content_type=content_type)

# execute the XGBoost training job
estimator.fit({'train': train_input, 'validation': validation_input})

```

#### SageMaker Python SDK v2

```

import sagemaker
import boto3
from sagemaker import image_uris
from sagemaker.session import Session
from sagemaker.inputs import TrainingInput

# initialize hyperparameters
hyperparameters = {

```

```

    "max_depth": "5",
    "eta": "0.2",
    "gamma": "4",
    "min_child_weight": "6",
    "subsample": "0.7",
    "objective": "reg:squarederror",
    "num_round": "50"}
```

```

# set an output path where the trained model will be saved
bucket = sagemaker.Session().default_bucket()
prefix = 'DEMO-xgboost-as-a-built-in-algo'
output_path = 's3://{}//{}//{}//output'.format(bucket, prefix, 'abalone-xgb-built-in-algo')

# this line automatically looks for the XGBoost image URI and builds an XGBoost
# container.
# specify the repo_version depending on your preference.
xgboost_container = sagemaker.image_uris.retrieve("xgboost", region, "1.2-2")

# construct a SageMaker estimator that calls the xgboost-container
estimator = sagemaker.estimator.Estimator(image_uri=xgboost_container,
                                            hyperparameters=hyperparameters,
                                            role=sagemaker.get_execution_role(),
                                            instance_count=1,
                                            instance_type='ml.m5.2xlarge',
                                            volume_size=5, # 5 GB
                                            output_path=output_path)

# define the data type and paths to the training and validation datasets
content_type = "libsvm"
train_input = TrainingInput("s3://{}//{}//{}//".format(bucket, prefix, 'train'),
                           content_type=content_type)
validation_input = TrainingInput("s3://{}//{}//{}//".format(bucket, prefix,
                           'validation'), content_type=content_type)

# execute the XGBoost training job
estimator.fit({'train': train_input, 'validation': validation_input})
```

For more information about how to set up the XGBoost as a built-in algorithm, see the following notebook examples.

- [Managed Spot Training for XGBoost](#)
- [Regression with Amazon SageMaker XGBoost \(Parquet input\)](#)

## Input/Output Interface for the XGBoost Algorithm

Gradient boosting operates on tabular data, with the rows representing observations, one column representing the target variable or label, and the remaining columns representing features.

The SageMaker implementation of XGBoost supports CSV and libsvm formats for training and inference:

- For Training ContentType, valid inputs are *text/libsvm* (default) or *text/csv*.
- For Inference ContentType, valid inputs are *text/libsvm* (default) or *text/csv*.

### Note

For CSV training, the algorithm assumes that the target variable is in the first column and that the CSV does not have a header record.

For CSV inference, the algorithm assumes that CSV input does not have the label column.

For libsvm training, the algorithm assumes that the label is in the first column. Subsequent columns contain the zero-based index value pairs for features. So each row has the format:

<label> <index0>:<value0> <index1>:<value1> ... Inference requests for libsvm might not have labels in the libsvm format.

This differs from other SageMaker algorithms, which use the protobuf training input format to maintain greater consistency with standard XGBoost data formats.

For CSV training input mode, the total memory available to the algorithm (Instance Count \* the memory available in the `InstanceType`) must be able to hold the training dataset. For libsvm training input mode, it's not required, but we recommend it.

SageMaker XGBoost uses the Python pickle module to serialize/deserialize the model, which can be used for saving/loading the model.

### To use a model trained with SageMaker XGBoost in open source XGBoost

- Use the following Python code:

```
import pickle as pkl
import tarfile

t = tarfile.open('model.tar.gz', 'r:gz')
t.extractall()

model = pkl.load(open(model_file_path, 'rb'))

# prediction with test data
pred = model.predict(dtest)
```

### To differentiate the importance of labelled data points use Instance Weight Supports

- SageMaker XGBoost allows customers to differentiate the importance of labelled data points by assigning each instance a weight value. For `text/libsvm` input, customers can assign weight values to data instances by attaching them after the labels. For example, `label:weight idx_0:val_0 idx_1:val_1...`. For `text/csv` input, customers need to turn on the `csv_weights` flag in the parameters and attach weight values in the column after labels. For example: `label,weight,val_0,val_1,...`.

## EC2 Instance Recommendation for the XGBoost Algorithm

SageMaker XGBoost 1.0-1 or earlier currently only trains using CPUs. It is a memory-bound (as opposed to compute-bound) algorithm. So, a general-purpose compute instance (for example, M5) is a better choice than a compute-optimized instance (for example, C4). Further, we recommend that you have enough total memory in selected instances to hold the training data. Although it supports the use of disk space to handle data that does not fit into main memory (the out-of-core feature available with the libsvm input mode), writing cache files onto disk slows the algorithm processing time.

SageMaker XGBoost version 1.2 or later supports single-instance GPU training. Despite higher per-instance costs, GPUs train more quickly, making them more cost effective. To take advantage of GPU training, specify the instance type as one of the GPU instances (for example, P3) and set the `tree_method` hyperparameter to `gpu_hist` in your existing XGBoost script. SageMaker currently does not support multi-GPU training.

## XGBoost Sample Notebooks

The following table outlines a variety of sample notebooks that address different use cases of Amazon SageMaker XGBoost algorithm.

Notebook Title	Description
<a href="#">How to Create a Custom XGBoost container?</a>	This notebook shows you how to build a custom XGBoost Container with Amazon SageMaker Batch Transform.
<a href="#">An Introduction to Feature Processing, Training and Inference</a>	This notebook shows you how to build a Machine Learning (ML) Pipeline using Spark Feature Transformers and do real-time inference using Amazon SageMaker Batch Transform.
<a href="#">Regression with XGBoost using Parquet</a>	This notebook shows you how to use the Abalone dataset in Parquet to train a XGBoost model.
<a href="#">How to Train and Host a Multiclass Classification Model?</a>	This notebook shows how to use the MNIST dataset to train and host a multiclass classification model.
<a href="#">How to train a Model for Customer Churn Prediction?</a>	This notebook shows you how to train a model to Predict Mobile Customer Departure in an effort to identify unhappy customers.
<a href="#">An Introduction to Amazon SageMaker Managed Spot infrastructure for XGBoost Training</a>	This notebook shows you how to use Spot Instances for training with a XGBoost Container.
<a href="#">How to use Amazon SageMaker Debugger to debug XGBoost Training Jobs?</a>	This notebook shows you how to use Amazon SageMaker Debugger to monitor training jobs to detect inconsistencies.
<a href="#">How to use Amazon SageMaker Debugger to debug XGBoost Training Jobs in Real-Time?</a>	This notebook shows you how to use the MNIST dataset and Amazon SageMaker Debugger to perform real-time analysis of XGBoost training jobs while training jobs are running.

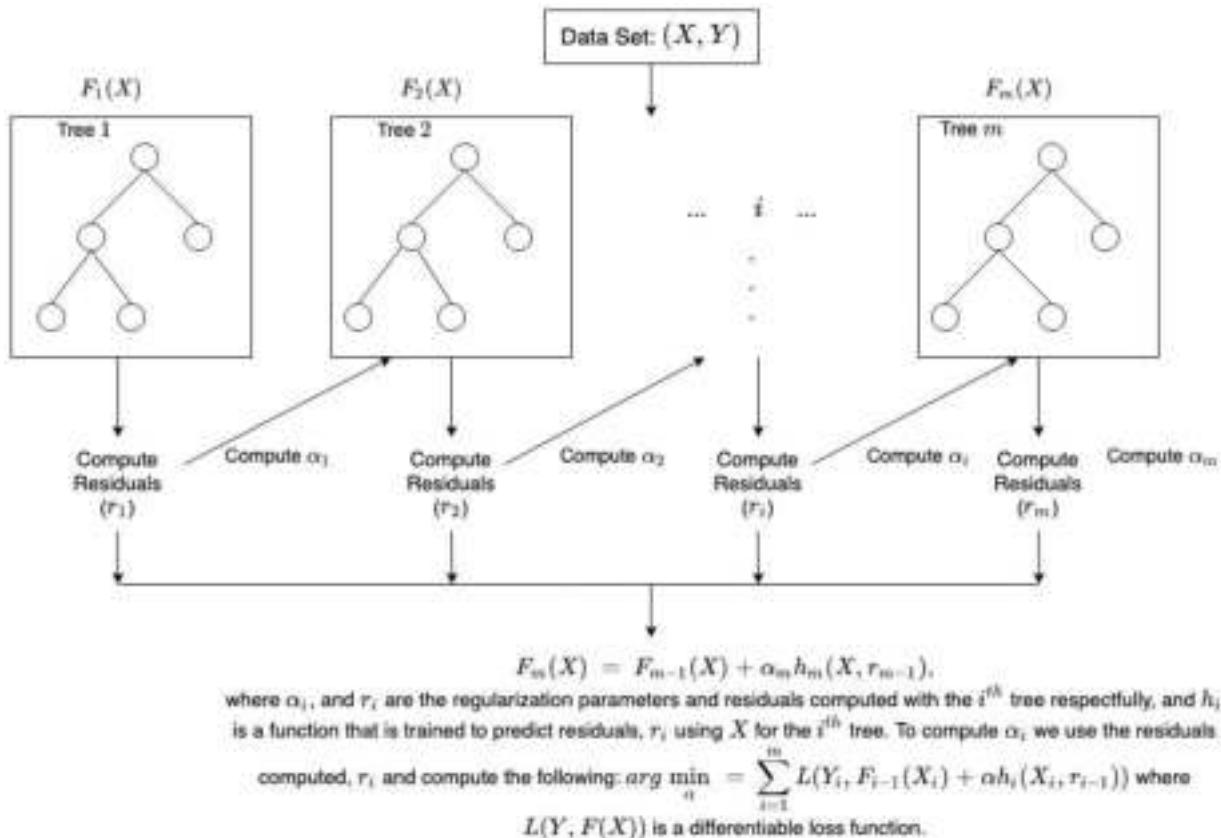

For instructions on how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see [Use Amazon SageMaker Notebook Instances \(p. 120\)](#). After you have created a notebook instance and opened it, choose the **SageMaker Examples** tab to see a list of all of the SageMaker samples. The topic modeling example notebooks using the linear learning algorithm are located in the **Introduction to Amazon algorithms** section. To open a notebook, choose its **Use** tab and choose **Create copy**.

## How XGBoost Works

XGBoost is a popular and efficient open-source implementation of the gradient boosted trees algorithm. Gradient boosting is a supervised learning algorithm, which attempts to accurately predict a target variable by combining the estimates of a set of simpler, weaker models.

When using **gradient boosting** for regression, the weak learners are regression trees, and each regression tree maps an input data point to one of its leafs that contains a continuous score. XGBoost minimizes a regularized (L1 and L2) objective function that combines a convex loss function (based on the difference between the predicted and target outputs) and a penalty term for model complexity (in other words, the regression tree functions). The training proceeds iteratively, adding new trees that predict the residuals or errors of prior trees that are then combined with previous trees to make the final prediction. It's called gradient boosting because it uses a gradient descent algorithm to minimize the loss when adding new models.

Below is a brief illustration on how gradient tree boosting works.

For more detail on XGBoost, see:

- [XGBoost: A Scalable Tree Boosting System](#)
- [Gradient Tree Boosting](#)
- [Introduction to Boosted Trees](#)

## XGBoost Hyperparameters

The following table contains the subset of hyperparameters that are required or most commonly used for the Amazon SageMaker XGBoost algorithm. These are parameters that are set by users to facilitate the estimation of model parameters from data. The required hyperparameters that must be set are listed first, in alphabetical order. The optional hyperparameters that can be set are listed next, also in alphabetical order. The SageMaker XGBoost algorithm is an implementation of the open-source DMLC XGBoost package. Currently SageMaker supports version 1.2-2. For details about full set of hyperparameter that can be configured for this version of XGBoost, see [XGBoost Parameters](#).

Parameter Name	Description
num_class	The number of classes. <b>Required</b> if objective is set to <i>multi:softmax</i> or <i>multi:softprob</i> . Valid values: integer
num_round	The number of rounds to run the training.

Parameter Name	Description
	<b>Required</b> Valid values: integer
alpha	L1 regularization term on weights. Increasing this value makes models more conservative. <b>Optional</b> Valid values: float Default value: 0
base_score	The initial prediction score of all instances, global bias. <b>Optional</b> Valid values: float Default value: 0.5
booster	Which booster to use. The <code>gbtree</code> and <code>dart</code> values use a tree-based model, while <code>gblinear</code> uses a linear function. <b>Optional</b> Valid values: String. One of <code>gbtree</code> , <code>gblinear</code> , or <code>dart</code> . Default value: <code>gbtree</code>
colsample_bylevel	Subsample ratio of columns for each split, in each level. <b>Optional</b> Valid values: Float. Range: [0,1]. Default value: 1
colsample_bynode	Subsample ratio of columns from each node. <b>Optional</b> Valid values: Float. Range: (0,1]. Default value: 1
colsample_bytree	Subsample ratio of columns when constructing each tree. <b>Optional</b> Valid values: Float. Range: [0,1]. Default value: 1

Parameter Name	Description
<code>csv_weights</code>	<p>When this flag is enabled, XGBoost differentiates the importance of instances for csv input by taking the second column (the column after labels) in training data as the instance weights.</p> <p><b>Optional</b></p> <p>Valid values: 0 or 1</p> <p>Default value: 0</p>
<code>deterministic_histogram</code>	<p>When this flag is enabled, XGBoost builds histogram on GPU deterministically. Used only if <code>tree_method</code> is set to <code>gpu_hist</code>.</p> <p>For a full list of valid inputs, please refer to <a href="#">XGBoost Parameters</a>.</p> <p><b>Optional</b></p> <p>Valid values: String. Range: <code>true</code> or <code>false</code></p> <p>Default value: <code>true</code></p>
<code>early_stopping_rounds</code>	<p>The model trains until the validation score stops improving. Validation error needs to decrease at least every <code>early_stopping_rounds</code> to continue training. SageMaker hosting uses the best model for inference.</p> <p><b>Optional</b></p> <p>Valid values: integer</p> <p>Default value: -</p>
<code>eta</code>	<p>Step size shrinkage used in updates to prevent overfitting. After each boosting step, you can directly get the weights of new features. The <code>eta</code> parameter actually shrinks the feature weights to make the boosting process more conservative.</p> <p><b>Optional</b></p> <p>Valid values: Float. Range: [0,1].</p> <p>Default value: 0.3</p>
<code>eval_metric</code>	<p>Evaluation metrics for validation data. A default metric is assigned according to the objective:</p> <ul style="list-style-type: none"> <li>• <code>rmse</code>: for regression</li> <li>• <code>error</code>: for classification</li> <li>• <code>map</code>: for ranking</li> </ul> <p>For a list of valid inputs, see <a href="#">XGBoost Learning Task Parameters</a>.</p> <p><b>Optional</b></p> <p>Valid values: string</p> <p>Default value: Default according to objective.</p>

Parameter Name	Description
gamma	<p>Minimum loss reduction required to make a further partition on a leaf node of the tree. The larger, the more conservative the algorithm is.</p> <p><b>Optional</b></p> <p>Valid values: Float. Range: <math>[0, \infty)</math>.</p> <p>Default value: 0</p>
grow_policy	<p>Controls the way that new nodes are added to the tree. Currently supported only if <code>tree_method</code> is set to <code>hist</code>.</p> <p><b>Optional</b></p> <p>Valid values: String. Either <code>depthwise</code> or <code>lossguide</code>.</p> <p>Default value: <code>depthwise</code></p>
interaction_constraints	<p>Specify groups of variables that are allowed to interact.</p> <p><b>Optional</b></p> <p>Valid values: Nested list of integers. Each integer represents a feature, and each nested list contains features that are allowed to interact e.g., <code>[[1,2], [3,4,5]]</code>.</p> <p>Default value: None</p>
lambda	<p>L2 regularization term on weights. Increasing this value makes models more conservative.</p> <p><b>Optional</b></p> <p>Valid values: float</p> <p>Default value: 1</p>
lambda_bias	<p>L2 regularization term on bias.</p> <p><b>Optional</b></p> <p>Valid values: Float. Range: <math>[0.0, 1.0]</math>.</p> <p>Default value: 0</p>
max_bin	<p>Maximum number of discrete bins to bucket continuous features. Used only if <code>tree_method</code> is set to <code>hist</code>.</p> <p><b>Optional</b></p> <p>Valid values: integer</p> <p>Default value: 256</p>

Parameter Name	Description
max_delta_step	<p>Maximum delta step allowed for each tree's weight estimation. When a positive integer is used, it helps make the update more conservative. The preferred option is to use it in logistic regression. Set it to 1-10 to help control the update.</p> <p><b>Optional</b></p> <p>Valid values: Integer. Range: <math>[0, \infty)</math>.</p> <p>Default value: 0</p>
max_depth	<p>Maximum depth of a tree. Increasing this value makes the model more complex and likely to be overfit. 0 indicates no limit. A limit is required when <code>grow_policy=depth-wise</code>.</p> <p><b>Optional</b></p> <p>Valid values: Integer. Range: <math>[0, \infty)</math></p> <p>Default value: 6</p>
max_leaves	<p>Maximum number of nodes to be added. Relevant only if <code>grow_policy</code> is set to <code>lossguide</code>.</p> <p><b>Optional</b></p> <p>Valid values: integer</p> <p>Default value: 0</p>
min_child_weight	<p>Minimum sum of instance weight (hessian) needed in a child. If the tree partition step results in a leaf node with the sum of instance weight less than <code>min_child_weight</code>, the building process gives up further partitioning. In linear regression models, this simply corresponds to a minimum number of instances needed in each node. The larger the algorithm, the more conservative it is.</p> <p><b>Optional</b></p> <p>Valid values: Float. Range: <math>[0, \infty)</math>.</p> <p>Default value: 1</p>
monotone_constraints	<p>Specifies monotonicity constraints on any feature.</p> <p><b>Optional</b></p> <p>Valid values: Tuple of Integers. Valid integers: -1 (decreasing constraint), 0 (no constraint), 1 (increasing constraint).</p> <p>E.g., (0, 1): No constraint on first predictor, and an increasing constraint on the second. (-1, 1): Decreasing constraint on first predictor, and an increasing constraint on the second.</p> <p>Default value: (0, 0)</p>

Parameter Name	Description
normalize_type	<p>Type of normalization algorithm.</p> <p><b>Optional</b></p> <p>Valid values: Either <i>tree</i> or <i>forest</i>.</p> <p>Default value: <i>tree</i></p>
nthread	<p>Number of parallel threads used to run <i>xgboost</i>.</p> <p><b>Optional</b></p> <p>Valid values: integer</p> <p>Default value: Maximum number of threads.</p>
objective	<p>Specifies the learning task and the corresponding learning objective. Examples: <code>reg:logistic</code>, <code>multi:softmax</code>, <code>reg:squarederror</code>. For a full list of valid inputs, refer to <a href="#">XGBoost Learning Task Parameters</a>.</p> <p><b>Optional</b></p> <p>Valid values: string</p> <p>Default value: <code>reg:squarederror</code></p>
one_drop	<p>When this flag is enabled, at least one tree is always dropped during the dropout.</p> <p><b>Optional</b></p> <p>Valid values: 0 or 1</p> <p>Default value: 0</p>
process_type	<p>The type of boosting process to run.</p> <p><b>Optional</b></p> <p>Valid values: String. Either <code>default</code> or <code>update</code>.</p> <p>Default value: <code>default</code></p>
rate_drop	<p>The dropout rate that specifies the fraction of previous trees to drop during the dropout.</p> <p><b>Optional</b></p> <p>Valid values: Float. Range: [0.0, 1.0].</p> <p>Default value: 0.0</p>

Parameter Name	Description
<code>refresh_leaf</code>	<p>This is a parameter of the 'refresh' updater plug-in. When set to <code>true</code>(1), tree leaves and tree node stats are updated. When set to <code>false</code>(0), only tree node stats are updated.</p> <p><b>Optional</b></p> <p>Valid values: 0/1</p> <p>Default value: 1</p>
<code>sample_type</code>	<p>Type of sampling algorithm.</p> <p><b>Optional</b></p> <p>Valid values: Either <code>uniform</code> or <code>weighted</code>.</p> <p>Default value: <code>uniform</code></p>
<code>scale_pos_weight</code>	<p>Controls the balance of positive and negative weights. It's useful for unbalanced classes. A typical value to consider: <code>sum(negative cases) / sum(positive cases)</code>.</p> <p><b>Optional</b></p> <p>Valid values: float</p> <p>Default value: 1</p>
<code>seed</code>	<p>Random number seed.</p> <p><b>Optional</b></p> <p>Valid values: integer</p> <p>Default value: 0</p>
<code>single_precision_histogram</code>	<p>When this flag is enabled, XGBoost uses single precision to build histograms instead of double precision. Used only if <code>tree_method</code> is set to <code>hist</code> or <code>gpu_hist</code>.</p> <p>For a full list of valid inputs, please refer to <a href="#">XGBoost Parameters</a>.</p> <p><b>Optional</b></p> <p>Valid values: String. Range: <code>true</code> or <code>false</code></p> <p>Default value: <code>false</code></p>
<code>sketch_eps</code>	<p>Used only for approximate greedy algorithm. This translates into <math>O(1 / \text{sketch\_eps})</math> number of bins. Compared to directly select number of bins, this comes with theoretical guarantee with sketch accuracy.</p> <p><b>Optional</b></p> <p>Valid values: Float, Range: [0, 1].</p> <p>Default value: 0.03</p>

Parameter Name	Description
skip_drop	<p>Probability of skipping the dropout procedure during a boosting iteration.</p> <p><b>Optional</b></p> <p>Valid values: Float. Range: [0.0, 1.0].</p> <p>Default value: 0.0</p>
subsample	<p>Subsample ratio of the training instance. Setting it to 0.5 means that XGBoost randomly collects half of the data instances to grow trees. This prevents overfitting.</p> <p><b>Optional</b></p> <p>Valid values: Float. Range: [0,1].</p> <p>Default value: 1</p>
tree_method	<p>The tree construction algorithm used in XGBoost.</p> <p><b>Optional</b></p> <p>Valid values: One of <code>auto</code>, <code>exact</code>, <code>approx</code>, <code>hist</code>, or <code>gpu_hist</code>.</p> <p>Default value: <code>auto</code></p>
tweedie_variance_power	<p>Parameter that controls the variance of the Tweedie distribution.</p> <p><b>Optional</b></p> <p>Valid values: Float. Range: (1, 2).</p> <p>Default value: 1.5</p>
updater	<p>A comma-separated string that defines the sequence of tree updaters to run. This provides a modular way to construct and to modify the trees.</p> <p>For a full list of valid inputs, please refer to <a href="#">XGBoost Parameters</a>.</p> <p><b>Optional</b></p> <p>Valid values: comma-separated string.</p> <p>Default value: <code>grow_colmaker</code>, <code>prune</code></p>
verbosity	<p>Verbosity of printing messages.</p> <p>Valid values: 0 (silent), 1 (warning), 2 (info), 3 (debug).</p> <p><b>Optional</b></p> <p>Default value: 1</p>

## Tune an XGBoost Model

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your training and validation datasets. You choose three types of hyperparameters:

- a learning objective function to optimize during model training
- an eval\_metric to use to evaluate model performance during validation
- a set of hyperparameters and a range of values for each to use when tuning the model automatically

You choose the evaluation metric from set of evaluation metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the evaluation metric.

**Note**

Automatic model tuning for XGBoost 0.90 is only available from the Amazon SageMaker SDKs, not from the SageMaker console.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker \(p. 1745\)](#).

### Evaluation Metrics Computed by the XGBoost Algorithm

The XGBoost algorithm computes the following metrics to use for model validation. When tuning the model, choose one of these metrics to evaluate the model. For full list of valid eval\_metric values, refer to [XGBoost Learning Task Parameters](#)

Metric Name	Description	Optimization Direction
validation:accuracy	Classification rate, calculated as #(right)/#(all cases).	Maximize
validation:auc	Area under the curve.	Maximize
validation:error	Binary classification error rate, calculated as #(wrong cases)/#(all cases).	Minimize
validation:f1	Indicator of classification accuracy, calculated as the harmonic mean of precision and recall.	Maximize
validation:logloss	Negative log-likelihood.	Minimize
validation:mae	Mean absolute error.	Minimize
validation:map	Mean average precision.	Maximize
validation:merror	Multiclass classification error rate, calculated as #(wrong cases)/#(all cases).	Minimize
validation:mlogloss	Negative log-likelihood for multiclass classification.	Minimize
validation:mse	Mean squared error.	Minimize
validation:ndcg	Normalized Discounted Cumulative Gain.	Maximize
validation:rmse	Root mean square error.	Minimize

## Tunable XGBoost Hyperparameters

Tune the XGBoost model with the following hyperparameters. The hyperparameters that have the greatest effect on optimizing the XGBoost evaluation metrics are: `alpha`, `min_child_weight`, `subsample`, `eta`, and `num_round`.

Parameter Name	Parameter Type	Recommended Ranges
<code>alpha</code>	ContinuousParameterRanges	MinValue: 0, MaxValue: 1000
<code>colsample_bylevel</code>	ContinuousParameterRanges	MinValue: 0.1, MaxValue: 1
<code>colsample_bynode</code>	ContinuousParameterRanges	MinValue: 0.1, MaxValue: 1
<code>colsample_bytree</code>	ContinuousParameterRanges	MinValue: 0.5, MaxValue: 1
<code>eta</code>	ContinuousParameterRanges	MinValue: 0.1, MaxValue: 0.5
<code>gamma</code>	ContinuousParameterRanges	MinValue: 0, MaxValue: 5
<code>lambda</code>	ContinuousParameterRanges	MinValue: 0, MaxValue: 1000
<code>max_delta_step</code>	IntegerParameterRanges	[0, 10]
<code>max_depth</code>	IntegerParameterRanges	[0, 10]
<code>min_child_weight</code>	ContinuousParameterRanges	MinValue: 0, MaxValue: 120
<code>num_round</code>	IntegerParameterRanges	[1, 4000]
<code>subsample</code>	ContinuousParameterRanges	MinValue: 0.5, MaxValue: 1

## Deprecated Versions of XGBoost and their Upgrades

This topic contains documentation for previous versions of Amazon SageMaker XGBoost that are still available but deprecated. It also provides instructions on how to upgrade deprecated versions of XGBoost, when possible, to more current versions.

### Topics

- [Upgrade XGBoost Version 0.90 to Version 1.2 \(p. 1540\)](#)
- [XGBoost Version 0.72 \(p. 1542\)](#)

### Upgrade XGBoost Version 0.90 to Version 1.2

If you are using the SageMaker Python SDK, to upgrade existing XGBoost 0.90 jobs to version 1.2, you must have version 2.x of the SDK installed and change the `XGBoost version` and `framework_version` parameters to 1.2-2. If you are using Boto3, you need to update the Docker image, and a few hyperparameters and learning objectives.

## Topics

- [Upgrade SageMaker Python SDK Version 1.x to Version 2.x \(p. 1541\)](#)
- [Change the image tag to 1.2-2 \(p. 1541\)](#)
- [Change Docker Image for Boto3 \(p. 1541\)](#)
- [Update Hyperparameters and Learning Objectives \(p. 1542\)](#)

## Upgrade SageMaker Python SDK Version 1.x to Version 2.x

If you are still using Version 1.x of the SageMaker Python SDK, you must upgrade version 2.x of the SageMaker Python SDK. For information on the latest version of the SageMaker Python SDK, see [Use Version 2.x of the SageMaker Python SDK](#). To install the latest version, run:

```
python -m pip install --upgrade sagemaker
```

## Change the image tag to 1.2-2

If you are using the SageMaker Python SDK and using the XGBoost build-in algorithm, change the version parameter in `image_uris.retrieve`.

```
from sagemaker import image_uris
image_uris.retrieve(framework="xgboost", region="us-west-2", version="1.2-2")

estimator = sagemaker.estimator.Estimator(image_uri=xgboost_container,
                                            hyperparameters=hyperparameters,
                                            role=sagemaker.get_execution_role(),
                                            instance_count=1,
                                            instance_type='ml.m5.2xlarge',
                                            volume_size=5, # 5 GB
                                            output_path=output_path)
```

If you are using the SageMaker Python SDK and using XGBoost as a framework to run your customized training scripts, change the `framework_version` parameter in the XGBoost API.

```
estimator = XGBoost(entry_point = "your_xgboost_abalone_script.py",
                     framework_version='1.2-2',
                     hyperparameters=hyperparameters,
                     role=sagemaker.get_execution_role(),
                     instance_count=1,
                     instance_type='ml.m5.2xlarge',
                     output_path=output_path)
```

`sagemaker.session.s3_input` in SageMaker Python SDK version 1.x has been renamed to `sagemaker.inputs.TrainingInput`. You must use `sagemaker.inputs.TrainingInput` as in the following example.

```
content_type = "libsvm"
train_input = TrainingInput("s3://{}//{}//{}//".format(bucket, prefix, 'train'),
                           content_type=content_type)
validation_input = TrainingInput("s3://{}//{}//{}//".format(bucket, prefix, 'validation'),
                                 content_type=content_type)
```

For the full list of SageMaker Python SDK version 2.x changes, see [Use Version 2.x of the SageMaker Python SDK](#).

## Change Docker Image for Boto3

If you are using Boto3 to train or deploy your model, change the docker image tag (0.90-1 or 0.90-2) to 1.2-2.

```
{  
    "AlgorithmSpecification": {  
        "TrainingImage": "746614075791.dkr.ecr.us-west-1.amazonaws.com/sagemaker-xgboost:1.2-2"  
    }  
    ...  
}
```

If you are using the SageMaker Python SDK to retrieve registry path, change the `version` parameter in `image_uris.retrieve`.

```
from sagemaker import image_uris  
image_uris.retrieve(framework="xgboost", region="us-west-2", version="1.2-2")
```

## Update Hyperparameters and Learning Objectives

The `silent` parameter has been deprecated and is no longer available in XGBoost 1.2 and later versions. Use `verbosity` instead. If you were using the `reg:linear` learning objective, it has been deprecated as well in favor of `reg:squarederror`. Use `reg:squarederror` instead.

```
hyperparameters = {  
    "verbosity": "2",  
    "objective": "reg:squarederror",  
    "num_round": "50",  
    ...  
}  
  
estimator = sagemaker.estimator.Estimator(image_uri=xgboost_container,  
                                         hyperparameters=hyperparameters,  
                                         ...)
```

## XGBoost Version 0.72

### Important

The XGBoost 0.72 is deprecated by Amazon SageMaker. You can still use this old version of XGBoost (as a built-in algorithm) by pulling its image URI as shown in the following code sample. For XGBoost, the image URI ending with `:1` is for the old version.

### SageMaker Python SDK v1

```
import boto3  
from sagemaker.amazon.amazon_estimator import get_image_uri  
  
xgb_image_uri = get_image_uri(boto3.Session().region_name, "xgboost",  
                           repo_version="1")
```

### SageMaker Python SDK v2

```
import boto3  
from sagemaker import image_uris  
  
xgb_image_uri = image_uris.retrieve("xgboost", boto3.Session().region_name, "1")
```

If you want to use newer versions, you have to explicitly specify the image URI tags (see [Supported versions \(p. 1525\)](#)).

This previous release of the Amazon SageMaker XGBoost algorithm is based on the 0.72 release. **XGBoost** (eXtreme Gradient Boosting) is a popular and efficient open-source implementation of

the gradient boosted trees algorithm. Gradient boosting is a supervised learning algorithm that attempts to accurately predict a target variable by combining the estimates of a set of simpler, weaker models. XGBoost has done remarkably well in machine learning competitions because it robustly handles a variety of data types, relationships, and distributions, and because of the large number of hyperparameters that can be tweaked and tuned for improved fits. This flexibility makes XGBoost a solid choice for problems in regression, classification (binary and multiclass), and ranking.

Customers should consider using the new release of [XGBoost Algorithm \(p. 1524\)](#). They can use it as a SageMaker built-in algorithm or as a framework to run scripts in their local environments as they would typically, for example, do with a Tensorflow deep learning framework. The new implementation has a smaller memory footprint, better logging, improved hyperparameter validation, and an expanded set of metrics. The earlier implementation of XGBoost remains available to customers if they need to postpone migrating to the new version. But this previous implementation will remain tied to the 0.72 release of XGBoost.

### [Input/Output Interface for the XGBoost Release 0.72](#)

Gradient boosting operates on tabular data, with the rows representing observations, one column representing the target variable or label, and the remaining columns representing features.

The SageMaker implementation of XGBoost supports CSV and libsvm formats for training and inference:

- For Training ContentType, valid inputs are *text/libsvm* (default) or *text/csv*.
- For Inference ContentType, valid inputs are *text/libsvm* or (the default) *text/csv*.

#### **Note**

For CSV training, the algorithm assumes that the target variable is in the first column and that the CSV does not have a header record. For CSV inference, the algorithm assumes that CSV input does not have the label column.

For libsvm training, the algorithm assumes that the label is in the first column. Subsequent columns contain the zero-based index value pairs for features. So each row has the format: <label> <index0>:<value0> <index1>:<value1> ... Inference requests for libsvm may or may not have labels in the libsvm format.

This differs from other SageMaker algorithms, which use the protobuf training input format to maintain greater consistency with standard XGBoost data formats.

For CSV training input mode, the total memory available to the algorithm (Instance Count \* the memory available in the `InstanceType`) must be able to hold the training dataset. For libsvm training input mode, it's not required, but we recommend it.

SageMaker XGBoost uses the Python pickle module to serialize/deserialize the model, which can be used for saving/loading the model.

### **To use a model trained with SageMaker XGBoost in open source XGBoost**

- Use the following Python code:

```
import pickle as pkl
import tarfile
import xgboost

t = tarfile.open('model.tar.gz', 'r:gz')
t.extractall()

model = pkl.load(open(model_file_path, 'rb'))

# prediction with test data
```

```
pred = model.predict(dttest)
```

## To differentiate the importance of labelled data points use Instance Weight Supports

- SageMaker XGBoost allows customers to differentiate the importance of labelled data points by assigning each instance a weight value. For `text/libsvm` input, customers can assign weight values to data instances by attaching them after the labels. For example, `label:weight idx_0:val_0 idx_1:val_1....` For `text/csv` input, customers need to turn on the `csv_weights` flag in the parameters and attach weight values in the column after labels. For example: `label,weight,val_0,val_1,...`.

## EC2 Instance Recommendation for the XGBoost Release 0.72

SageMaker XGBoost currently only trains using CPUs. It is a memory-bound (as opposed to compute-bound) algorithm. So, a general-purpose compute instance (for example, M4) is a better choice than a compute-optimized instance (for example, C4). Further, we recommend that you have enough total memory in selected instances to hold the training data. Although it supports the use of disk space to handle data that does not fit into main memory (the out-of-core feature available with the `libsvm` input mode), writing cache files onto disk slows the algorithm processing time.

### XGBoost Release 0.72 Sample Notebooks

For a sample notebook that shows how to use the latest version of SageMaker XGBoost as a built-in algorithm to train and host a regression model, see [Regression with Amazon SageMaker XGBoost algorithm](#). To use the 0.72 version of XGBoost, you need to change the version in the sample code to 0.72. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see [Use Amazon SageMaker Notebook Instances \(p. 120\)](#). Once you have created a notebook instance and opened it, select the **SageMaker Examples** tab to see a list of all the SageMaker samples. The topic modeling example notebooks using the XGBoost algorithms are located in the **Introduction to Amazon algorithms** section. To open a notebook, click on its **Use** tab and select **Create copy**.

### XGBoost Release 0.72 Hyperparameters

The following table contains the hyperparameters for the XGBoost algorithm. These are parameters that are set by users to facilitate the estimation of model parameters from data. The required hyperparameters that must be set are listed first, in alphabetical order. The optional hyperparameters that can be set are listed next, also in alphabetical order. The SageMaker XGBoost algorithm is an implementation of the open-source XGBoost package. Currently SageMaker supports version 0.72. For more detail about hyperparameter configuration for this version of XGBoost, see [XGBoost Parameters](#).

Parameter Name	Description
<code>num_class</code>	The number of classes. <b>Required</b> if <code>objective</code> is set to <code>multi:softmax</code> or <code>multi:softprob</code> . Valid values: integer
<code>num_round</code>	The number of rounds to run the training. <b>Required</b> Valid values: integer
<code>alpha</code>	L1 regularization term on weights. Increasing this value makes models more conservative.

Parameter Name	Description
	<b>Optional</b> Valid values: float Default value: 0
<code>base_score</code>	The initial prediction score of all instances, global bias. <b>Optional</b> Valid values: float Default value: 0.5
<code>booster</code>	Which booster to use. The <code>gbtree</code> and <code>dart</code> values use a tree-based model, while <code>gblinear</code> uses a linear function. <b>Optional</b> Valid values: String. One of <code>gbtree</code> , <code>gblinear</code> , or <code>dart</code> . Default value: <code>gbtree</code>
<code>colsample_bylevel</code>	Subsample ratio of columns for each split, in each level. <b>Optional</b> Valid values: Float. Range: [0,1]. Default value: 1
<code>colsample_bytree</code>	Subsample ratio of columns when constructing each tree. <b>Optional</b> Valid values: Float. Range: [0,1]. Default value: 1
<code>csv_weights</code>	When this flag is enabled, XGBoost differentiates the importance of instances for csv input by taking the second column (the column after labels) in training data as the instance weights. <b>Optional</b> Valid values: 0 or 1 Default value: 0
<code>early_stopping_rounds</code>	The model trains until the validation score stops improving. Validation error needs to decrease at least every <code>early_stopping_rounds</code> to continue training. SageMaker hosting uses the best model for inference. <b>Optional</b> Valid values: integer Default value: -

Parameter Name	Description
eta	<p>Step size shrinkage used in updates to prevent overfitting. After each boosting step, you can directly get the weights of new features. The eta parameter actually shrinks the feature weights to make the boosting process more conservative.</p> <p><b>Optional</b></p> <p>Valid values: Float. Range: [0,1].</p> <p>Default value: 0.3</p>
eval_metric	<p>Evaluation metrics for validation data. A default metric is assigned according to the objective:</p> <ul style="list-style-type: none"> <li>• <code>rmse</code>: for regression</li> <li>• <code>error</code>: for classification</li> <li>• <code>map</code>: for ranking</li> </ul> <p>For a list of valid inputs, see <a href="#">XGBoost Parameters</a>.</p> <p><b>Optional</b></p> <p>Valid values: string</p> <p>Default value: Default according to objective.</p>
gamma	<p>Minimum loss reduction required to make a further partition on a leaf node of the tree. The larger, the more conservative the algorithm is.</p> <p><b>Optional</b></p> <p>Valid values: Float. Range: [0,∞).</p> <p>Default value: 0</p>
grow_policy	<p>Controls the way that new nodes are added to the tree. Currently supported only if <code>tree_method</code> is set to <code>hist</code>.</p> <p><b>Optional</b></p> <p>Valid values: String. Either <code>depthwise</code> or <code>lossguide</code>.</p> <p>Default value: <code>depthwise</code></p>
lambda	<p>L2 regularization term on weights. Increasing this value makes models more conservative.</p> <p><b>Optional</b></p> <p>Valid values: float</p> <p>Default value: 1</p>

Parameter Name	Description
<code>lambda_bias</code>	<p>L2 regularization term on bias.</p> <p><b>Optional</b></p> <p>Valid values: Float. Range: [0.0, 1.0].</p> <p>Default value: 0</p>
<code>max_bin</code>	<p>Maximum number of discrete bins to bucket continuous features. Used only if <code>tree_method</code> is set to <code>hist</code>.</p> <p><b>Optional</b></p> <p>Valid values: integer</p> <p>Default value: 256</p>
<code>max_delta_step</code>	<p>Maximum delta step allowed for each tree's weight estimation. When a positive integer is used, it helps make the update more conservative. The preferred option is to use it in logistic regression. Set it to 1-10 to help control the update.</p> <p><b>Optional</b></p> <p>Valid values: Integer. Range: [0,∞).</p> <p>Default value: 0</p>
<code>max_depth</code>	<p>Maximum depth of a tree. Increasing this value makes the model more complex and likely to be overfit. 0 indicates no limit. A limit is required when <code>grow_policy=depth-wise</code>.</p> <p><b>Optional</b></p> <p>Valid values: Integer. Range: [0,∞)</p> <p>Default value: 6</p>
<code>max_leaves</code>	<p>Maximum number of nodes to be added. Relevant only if <code>grow_policy</code> is set to <code>lossguide</code>.</p> <p><b>Optional</b></p> <p>Valid values: integer</p> <p>Default value: 0</p>
<code>min_child_weight</code>	<p>Minimum sum of instance weight (hessian) needed in a child. If the tree partition step results in a leaf node with the sum of instance weight less than <code>min_child_weight</code>, the building process gives up further partitioning. In linear regression models, this simply corresponds to a minimum number of instances needed in each node. The larger the algorithm, the more conservative it is.</p> <p><b>Optional</b></p> <p>Valid values: Float. Range: [0,∞).</p> <p>Default value: 1</p>

Parameter Name	Description
normalize_type	<p>Type of normalization algorithm.</p> <p><b>Optional</b></p> <p>Valid values: Either <i>tree</i> or <i>forest</i>.</p> <p>Default value: <i>tree</i></p>
nthread	<p>Number of parallel threads used to run <i>xgboost</i>.</p> <p><b>Optional</b></p> <p>Valid values: integer</p> <p>Default value: Maximum number of threads.</p>
objective	<p>Specifies the learning task and the corresponding learning objective. Examples: <i>reg:logistic</i>, <i>reg:softmax</i>, <i>multi:squarederror</i>. For a full list of valid inputs, refer to <a href="#">XGBoost Parameters</a>.</p> <p><b>Optional</b></p> <p>Valid values: string</p> <p>Default value: <i>reg:squarederror</i></p>
one_drop	<p>When this flag is enabled, at least one tree is always dropped during the dropout.</p> <p><b>Optional</b></p> <p>Valid values: 0 or 1</p> <p>Default value: 0</p>
process_type	<p>The type of boosting process to run.</p> <p><b>Optional</b></p> <p>Valid values: String. Either <i>default</i> or <i>update</i>.</p> <p>Default value: <i>default</i></p>
rate_drop	<p>The dropout rate that specifies the fraction of previous trees to drop during the dropout.</p> <p><b>Optional</b></p> <p>Valid values: Float. Range: [0.0, 1.0].</p> <p>Default value: 0.0</p>

Parameter Name	Description
<code>refresh_leaf</code>	<p>This is a parameter of the 'refresh' updater plug-in. When set to <code>true</code> (1), tree leaves and tree node stats are updated. When set to <code>false</code>(0), only tree node stats are updated.</p> <p><b>Optional</b></p> <p>Valid values: 0/1</p> <p>Default value: 1</p>
<code>sample_type</code>	<p>Type of sampling algorithm.</p> <p><b>Optional</b></p> <p>Valid values: Either <code>uniform</code> or <code>weighted</code>.</p> <p>Default value: <code>uniform</code></p>
<code>scale_pos_weight</code>	<p>Controls the balance of positive and negative weights. It's useful for unbalanced classes. A typical value to consider: <code>sum(negative cases) / sum(positive cases)</code>.</p> <p><b>Optional</b></p> <p>Valid values: float</p> <p>Default value: 1</p>
<code>seed</code>	<p>Random number seed.</p> <p><b>Optional</b></p> <p>Valid values: integer</p> <p>Default value: 0</p>
<code>silent</code>	<p>0 means print running messages, 1 means silent mode.</p> <p>Valid values: 0 or 1</p> <p><b>Optional</b></p> <p>Default value: 0</p>
<code>sketch_eps</code>	<p>Used only for approximate greedy algorithm. This translates into <math>O(1 / \text{sketch\_eps})</math> number of bins. Compared to directly select number of bins, this comes with theoretical guarantee with sketch accuracy.</p> <p><b>Optional</b></p> <p>Valid values: Float, Range: [0, 1].</p> <p>Default value: 0.03</p>

Parameter Name	Description
<code>skip_drop</code>	<p>Probability of skipping the dropout procedure during a boosting iteration.</p> <p><b>Optional</b></p> <p>Valid values: Float. Range: [0.0, 1.0].</p> <p>Default value: 0.0</p>
<code>subsample</code>	<p>Subsample ratio of the training instance. Setting it to 0.5 means that XGBoost randomly collects half of the data instances to grow trees. This prevents overfitting.</p> <p><b>Optional</b></p> <p>Valid values: Float. Range: [0,1].</p> <p>Default value: 1</p>
<code>tree_method</code>	<p>The tree construction algorithm used in XGBoost.</p> <p><b>Optional</b></p> <p>Valid values: One of <code>auto</code>, <code>exact</code>, <code>approx</code>, or <code>hist</code>.</p> <p>Default value: <code>auto</code></p>
<code>tweedie_variance_power</code>	<p>Parameter that controls the variance of the Tweedie distribution.</p> <p><b>Optional</b></p> <p>Valid values: Float. Range: (1, 2).</p> <p>Default value: 1.5</p>
<code>updater</code>	<p>A comma-separated string that defines the sequence of tree updaters to run. This provides a modular way to construct and to modify the trees.</p> <p>For a full list of valid inputs, please refer to <a href="#">XGBoost Parameters</a>.</p> <p><b>Optional</b></p> <p>Valid values: comma-separated string.</p> <p>Default value: <code>grow_colmaker</code>, <code>prune</code></p>

## Tune an XGBoost Release 0.72 Model

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your training and validation datasets. You choose three types of hyperparameters:

- a learning objective function to optimize during model training
- an `eval_metric` to use to evaluate model performance during validation
- a set of hyperparameters and a range of values for each to use when tuning the model automatically

You choose the evaluation metric from set of evaluation metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the evaluation metric.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker \(p. 1745\)](#).

### Metrics Computed by the XGBoost Release 0.72 Algorithm

The XGBoost algorithm based on version 0.72 computes the following nine metrics to use for model validation. When tuning the model, choose one of these metrics to evaluate the model. For full list of valid `eval_metric` values, refer to [XGBoost Learning Task Parameters](#)

Metric Name	Description	Optimization Direction
<code>validation:auc</code>	Area under the curve.	Maximize
<code>validation:error</code>	Binary classification error rate, calculated as #(wrong cases)/#(all cases).	Minimize
<code>validation:logloss</code>	Negative log-likelihood.	Minimize
<code>validation:mae</code>	Mean absolute error.	Minimize
<code>validation:map</code>	Mean average precision.	Maximize
<code>validation:merror</code>	Multiclass classification error rate, calculated as #(wrong cases)/#(all cases).	Minimize
<code>validation:mlogloss</code>	Negative log-likelihood for multiclass classification.	Minimize
<code>validation:ndcg</code>	Normalized Discounted Cumulative Gain.	Maximize
<code>validation:rmse</code>	Root mean square error.	Minimize

### Tunable XGBoost Release 0.72 Hyperparameters

Tune the XGBoost model with the following hyperparameters. The hyperparameters that have the greatest effect on optimizing the XGBoost evaluation metrics are: `alpha`, `min_child_weight`, `subsample`, `eta`, and `num_round`.

Parameter Name	Parameter Type	Recommended Ranges
<code>alpha</code>	ContinuousParameterRanges	MinValue: 0, MaxValue: 1000
<code>colsample_bylevel</code>	ContinuousParameterRanges	MinValue: 0.1, MaxValue: 1
<code>colsample_bytree</code>	ContinuousParameterRanges	MinValue: 0.5, MaxValue: 1
<code>eta</code>	ContinuousParameterRanges	MinValue: 0.1, MaxValue: 0.5
<code>gamma</code>	ContinuousParameterRanges	MinValue: 0, MaxValue: 5

Parameter Name	Parameter Type	Recommended Ranges
lambda	ContinuousParameterRanges	MinValue: 0, MaxValue: 1000
max_delta_step	IntegerParameterRanges	[0, 10]
max_depth	IntegerParameterRanges	[0, 10]
min_child_weight	ContinuousParameterRanges	MinValue: 0, MaxValue: 120
num_round	IntegerParameterRanges	[1, 4000]
subsample	ContinuousParameterRanges	MinValue: 0.5, MaxValue: 1

## Use Reinforcement Learning with Amazon SageMaker

Reinforcement learning (RL) combines fields such as computer science, neuroscience, and psychology to determine how to map situations to actions to maximize a numerical reward signal. This notion of a reward signal in RL stems from neuroscience research into how the human brain makes decisions about which actions maximize reward and minimize punishment. In most situations, humans are not given explicit instructions on which actions to take, but instead must learn both which actions yield the most immediate rewards, and how those actions influence future situations and consequences.

The problem of RL is formalized using Markov decision processes (MDPs) that originate from dynamical systems theory. MDPs aim to capture high-level details of a real problem that a learning agent encounters over some period of time in attempting to achieve some ultimate goal. The learning agent should be able to determine the current state of its environment and identify possible actions that affect the learning agent's current state. Furthermore, the learning agent's goals should correlate strongly to the state of the environment. A solution to a problem formulated in this way is known as a reinforcement learning method.

### What are the differences between reinforcement, supervised, and unsupervised learning paradigms?

Machine learning can be divided into three distinct learning paradigms: supervised, unsupervised, and reinforcement.

In supervised learning, an external supervisor provides a training set of labeled examples. Each example contains information about a situation, belongs to a category, and has a label identifying the category to which it belongs. The goal of supervised learning is to generalize in order to predict correctly in situations that are not present in the training data.

In contrast, RL deals with interactive problems, making it infeasible to gather all possible examples of situations with correct labels that an agent might encounter. This type of learning is most promising when an agent is able to accurately learn from its own experience and adjust accordingly.

In unsupervised learning, an agent learns by uncovering structure within unlabeled data. While a RL agent might benefit from uncovering structure based on its experiences, the sole purpose of RL is to maximize a reward signal.

# Manage Machine Learning with Amazon SageMaker Experiments

Amazon SageMaker Experiments is a capability of Amazon SageMaker that lets you organize, track, compare, and evaluate your machine learning experiments.

Machine learning is an iterative process. You need to experiment with multiple combinations of data, algorithm and parameters, all the while observing the impact of incremental changes on model accuracy. Over time this iterative experimentation can result in thousands of model training runs and model versions. This makes it hard to track the best performing models and their input configurations. It's also difficult to compare active experiments with past experiments to identify opportunities for further incremental improvements.

SageMaker Experiments automatically tracks the inputs, parameters, configurations, and results of your iterations as *trials*. You can assign, group, and organize these trials into *experiments*. SageMaker Experiments is integrated with Amazon SageMaker Studio providing a visual interface to browse your active and past experiments, compare trials on key performance metrics, and identify the best performing models.

SageMaker Experiments comes with its own [Experiments Python SDK](#) which makes the analytics capabilities easily accessible in Amazon SageMaker Notebooks. Because SageMaker Experiments enables tracking of all the steps and artifacts that went into creating a model, you can quickly revisit the origins of a model when you are troubleshooting issues in production, or auditing your models for compliance verifications.

## Topics

- [SageMaker Experiments Features \(p. 1553\)](#)
- [Create an Amazon SageMaker Experiment \(p. 1554\)](#)
- [View and Compare Amazon SageMaker Experiments, Trials, and Trial Components \(p. 1558\)](#)
- [Track and Compare Tutorial \(p. 1561\)](#)
- [Search Experiments Using Amazon SageMaker Studio \(p. 1567\)](#)
- [Clean Up Amazon SageMaker Experiment Resources \(p. 1572\)](#)
- [Search Using the Amazon SageMaker Console and API \(p. 1574\)](#)

## SageMaker Experiments Features

The following sections provide a brief overview of the features provided by SageMaker Experiments.

## Topics

- [Organize Experiments \(p. 1553\)](#)
- [Track Experiments \(p. 1554\)](#)
- [Compare and Evaluate Experiments \(p. 1554\)](#)
- [Amazon SageMaker Autopilot \(p. 1554\)](#)

## Organize Experiments

Amazon SageMaker Experiments offers a structured organization scheme to help users group and organize their machine learning iterations. The top level entity, an *experiment*, is a collection of *trials* that are observed, compared, and evaluated as a group. A trial is a set of steps called *trial components*.

Each trial component can include a combination of inputs such as datasets, algorithms, and parameters, and produce specific outputs such as models, metrics, datasets, and checkpoints. Examples of trial components are data pre-processing jobs, training jobs, and batch transform jobs.

The goal of an experiment is to determine the trial that produces the best model. Multiple trials are performed, each one isolating and measuring the impact of a change to one or more inputs, while keeping the remaining inputs constant. By analyzing the trials, you can determine which features have the most effect on the model.

## Track Experiments

Amazon SageMaker Experiments enables tracking of experiments.

### Automated Tracking

SageMaker Experiments automatically tracks Amazon SageMaker Autopilot jobs as experiments with their underlying training jobs tracked as trials. SageMaker Experiments also automatically tracks SageMaker independently executed training, batch transform, and processing jobs as trial components, whether assigned to a trial or left unassigned. Unassigned trial components can be associated with a trial at a later time. All experiment artifacts including datasets, algorithms, hyperparameters, and model metrics are tracked and recorded. This data allows customers to trace the complete lineage of a model which helps with model governance, auditing, and compliance verifications.

### Manual Tracking

SageMaker Experiments provides [tracking APIs](#) for recording and tracking machine learning workflows running locally on SageMaker Studio notebooks, including classic SageMaker notebooks. These experiments must be part of a SageMaker training, batch transform, or processing job.

## Compare and Evaluate Experiments

Amazon SageMaker Experiments is integrated with Amazon SageMaker Studio. When you use SageMaker Studio, SageMaker Experiments automatically tracks your experiments and trials, and presents visualizations of the tracked data and an interface to search the data.

SageMaker Experiments automatically organizes, ranks, and sorts trials based on a chosen metric using the concept of a trial leaderboard. SageMaker Studio produces real-time data visualizations, such as metric charts and graphs, to quickly compare and identify the best performing models. These are updated in real-time as the experiment progresses.

## Amazon SageMaker Autopilot

Amazon SageMaker Experiments is integrated with Amazon SageMaker Autopilot. When you perform an Autopilot job, SageMaker Experiments creates an experiment for the job, and trials for each of the different combinations of the available trial components, parameters, and artifacts. You can visually drill into all trials and components using SageMaker Studio.

## Create an Amazon SageMaker Experiment

Create an Amazon SageMaker experiment to track your SageMaker training, processing, and transform jobs.

The following procedure shows you how to create a SageMaker experiment for a SageMaker training, processing, or transform job. Steps labeled as (Studio) describe how to view the experiment in Amazon SageMaker Studio. You don't have to run the experiment in Studio to view the experiment in Studio.

For a tutorial that shows this functionality in an existing SageMaker Studio notebook, see [Track and Compare Tutorial \(p. 1561\)](#).

1. Import the `sys` module to install the SDKs.

```
import sys
```

2. (Optional) The [Amazon SageMaker Python SDK](#), comes preinstalled in SageMaker Studio. If you plan to run your code outside Studio, install the SageMaker Python SDK.

```
!{sys.executable} -m pip install sagemaker
```

3. Install the [SageMaker Experiments Python SDK](#).

```
!{sys.executable} -m pip install sagemaker-experiments
```

4. Import modules.

```
import time
from time import strftime

import sagemaker

from smexperiments.experiment import Experiment
from smexperiments.trial import Trial
from smexperiments.trial_component import TrialComponent
from smexperiments.tracker import Tracker
```

5. Get the execution role and create the SageMaker session.

```
role = sagemaker.get_execution_role()
sm_sess = sagemaker.Session()
```

6. Create a SageMaker experiment. The experiment name must be unique in your account.

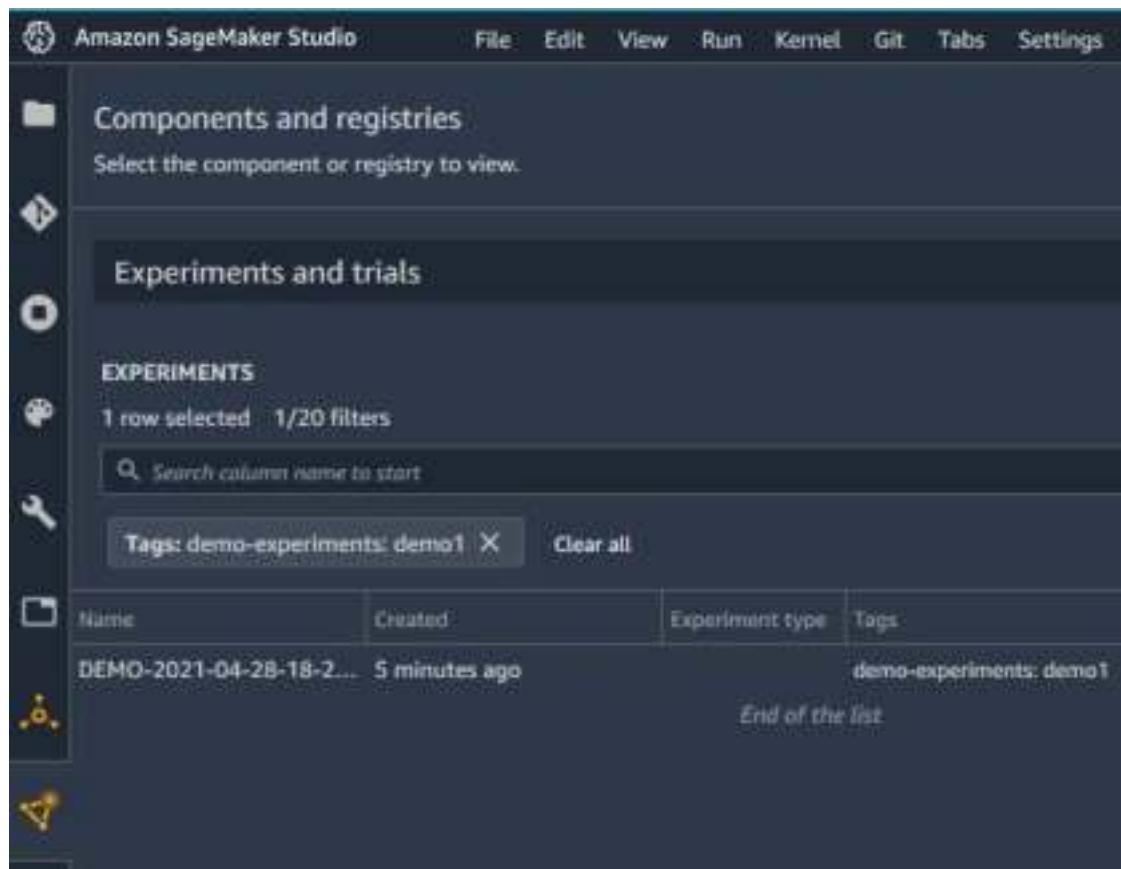

**Note**

The `tags` parameter is optional. You can search for the tag using Studio, the SageMaker console, and the SDK. Tags can also be applied to trials and trial components. For information on how to search tags using Studio, see [Search by Tag \(p. 1571\)](#).

```
create_date = strftime("%Y-%m-%d-%H-%M-%S")
demo_experiment = Experiment.create(experiment_name = "DEMO-{}".format(create_date),
                                     description = "Demo experiment",
                                     tags = [{'Key': 'demo-experiments', 'Value': 'demo1'}])
```

7. (Studio) To view the experiment in SageMaker Studio, in the left sidebar, choose the **Components and registries** icon (). In the drop-down menu, select **Experiments and trials** to display the experiments browser.

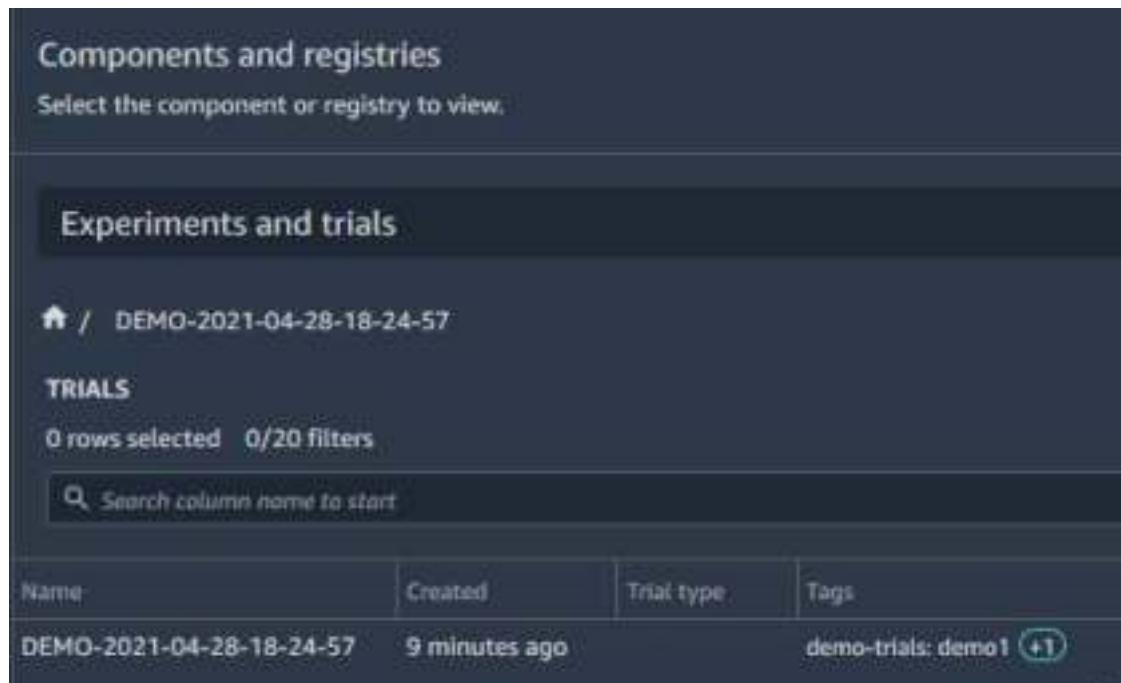

After the code runs, the experiment list contains the new experiment. It might take a moment for the list to refresh and display the experiment. The filter on the experiment tag is also displayed. Only experiments that have a matching tag are displayed. Your list should look similar to the following:

8. Create a trial for the experiment. The trial name must be unique in your account.

```
demo_trial = Trial.create(trial_name = "DEMO-{}".format(create_date),
                           experiment_name = demo_experiment.experiment_name,
                           tags = [{"Key": 'demo-trials', 'Value': 'demo1'}])
```

9. (Studio) In the experiment list, double-click the experiment to display a list of the trials in the experiment (this example has one trial). Your list should look similar to the following:

10. Create a trial component as part of the trial. The trial component is the SageMaker job.

Add the [ExperimentConfig](#) parameter to the appropriate method. The SageMaker jobs listed in the following table are supported.

Job	SageMaker Python SDK method	Boto3 method
Training	<a href="#">Estimator.fit</a>	<a href="#">CreateTrainingJob</a>
Processing	<a href="#">Processor.run</a>	<a href="#">CreateProcessingJob</a>
Transform	<a href="#">Transformer.transform</a>	<a href="#">CreateTransformJob</a>

The following examples are for a training job. The `Tags` parameter adds a tag to the trial component. `ExperimentName` isn't specified because the trial was associated with the experiment when the trial was created in an earlier step.

### Using the SageMaker Python SDK

```
sagemaker.estimator.Estimator(  
    ...,  
    sagemaker_session = sm_sess,  
    tags = [{'Key': 'demo-jobs', 'Value': 'demo2'}])  
  
estimator.fit(  
    ...,  
    experiment_config = {  
        # "ExperimentName"  
        "TrialName" : demo_trial.trial_name,  
        "TrialComponentDisplayName" : "TrainingJob",  
    })
```

### Using Boto3

```
create_training_job(  
    ...  
    "ExperimentConfig": {  
        # "ExperimentName"  
        "TrialName" : demo_trial.trial_name,  
        "TrialComponentDisplayName" : "TrainingJob",  
    },  
    "Tags": [{"Key': 'demo-jobs', 'Value': 'demo2'}])
```

11. (Studio) In the trial list, double-click the trial to display a list of the components in the trial (this example has one trial). Your list should look similar to the following:

The screenshot shows a dark-themed user interface for Amazon SageMaker Studio. At the top, there is a breadcrumb navigation bar with icons for Home and a trial identifier: / DEMO-2020-07-15-16-36-08 / DEMO-2020-07-15-16-36-08 /. Below this is a section titled "TRIAL COMPONENTS" with the subtext "0 rows selected 0/20 filters". A search bar contains the placeholder "Search column name to start". A "Clear all" button is present. The main area displays a table with four columns: "Name", "Created", "Trial component type", and "Tags". One row is visible, showing "TrainingJob" under "Name", "9 minutes ago" under "Created", "Training job" under "Trial component type", and "demo-jobs: demo2" under "Tags". A message "End of the list" is at the bottom right of the table area.

Name	Created	Trial component type	Tags
TrainingJob	9 minutes ago	Training job	demo-jobs: demo2

12. (Studio) To view information about the experiment, trial, and job (trial component), see [View and Compare Amazon SageMaker Experiments, Trials, and Trial Components \(p. 1558\)](#).

To clean up the resources you created, see [Clean Up Amazon SageMaker Experiment Resources \(p. 1572\)](#).

## View and Compare Amazon SageMaker Experiments, Trials, and Trial Components

An Amazon SageMaker *experiment* consists of multiple *trials* with a related objective. A trial consists of one or more *trial components*, such as a data preprocessing job and a training job.

You use the experiments browser to display a list of these entities. You can filter the list by entity name, type, and tags. The entities are presented in a hierarchical view (that is, experiments > trials > trial components). Double-click an entity to see other entities that are at a lower level in the hierarchy. Use the breadcrumbs above the list to move to a higher level in the hierarchy.

For a tutorial using a SageMaker example notebook, see [Track and Compare Tutorial \(p. 1561\)](#). For an overview of the Studio user interface, see [Amazon SageMaker Studio UI Overview \(p. 69\)](#).

### Topics

- [View Experiments, Trials, and Trial Components \(p. 1559\)](#)
- [Compare Experiments, Trials, and Trial Components \(p. 1560\)](#)

## View Experiments, Trials, and Trial Components

Amazon SageMaker Studio provides an experiments browser that you can use to view lists of experiments, trials, and trial components. You can choose one of these entities to view detailed information about the entity or choose multiple entities for comparison.

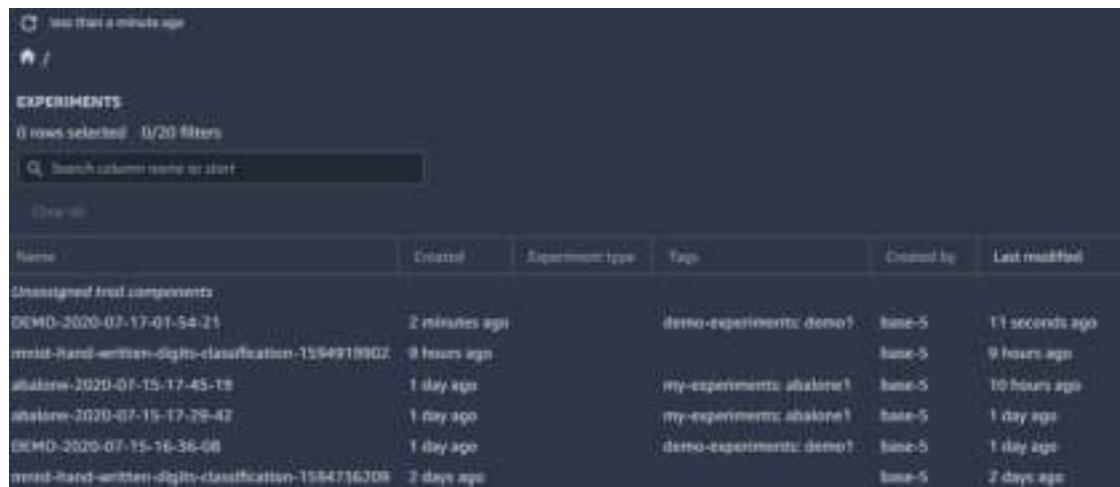

### To view experiments, trials, and trial components

1. In the left sidebar of Studio, choose the **Components and registries** icon (💡). In the drop-down menu, select **Experiments and trials** to display the experiments browser.

A list of experiments and their properties is displayed. The list includes all the SageMaker experiments in your account, including experiments created outside of SageMaker Studio.

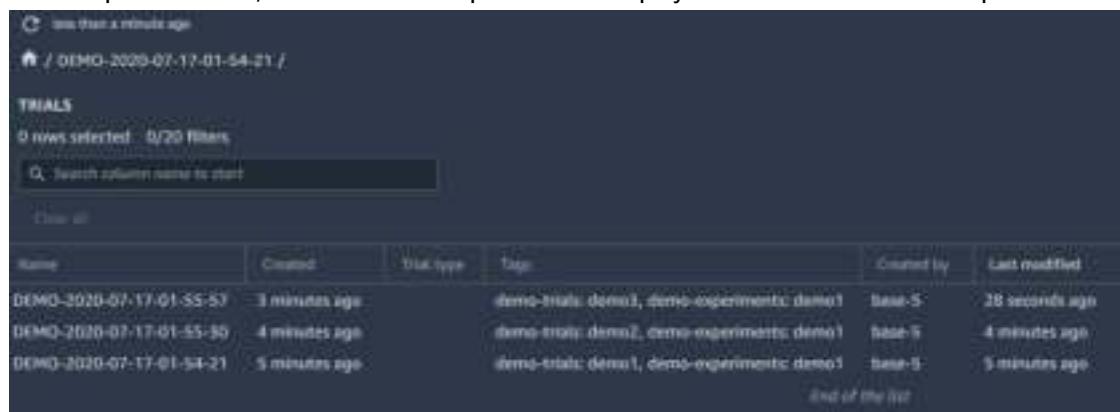

#### Note

To view all the properties, you might have to expand the width of the experiments browser by dragging the right border.

Name	Created	Experiment type	Tags	Created by	Last modified
Untagged trial components					
DEMO-2020-07-17-01-54-21	2 minutes ago		demo-experiments: demo1	base-S	11 seconds ago
mnist-hand-written-digits-classification-1584919902	9 hours ago			base-S	9 hours ago
analone-2020-07-15-17-45-13	1 day ago		my-experiments: analone1	base-S	10 hours ago
analone-2020-07-15-17-29-42	1 day ago		my-experiments: analone1	base-S	1 day ago
DEMO-2020-07-15-16-36-08	1 day ago		demo-experiments: demo1	base-S	1 day ago
mnist-hand-written-digits-classification-1584796308	2 days ago			base-S	2 days ago

2. In the experiments list, double-click an experiment to display a list of the trials in the experiment.

Name	Created	Trial type	Tags	Created by	Last modified
DEMO-2020-07-17-01-54-21 /					
DEMO-2020-07-17-01-55-53	3 minutes ago		demo-trials: demo1, demo-experiments: demo1	base-S	38 seconds ago
DEMO-2020-07-17-01-55-30	4 minutes ago		demo-trials: demo2, demo-experiments: demo1	base-S	4 minutes ago
DEMO-2020-07-17-01-54-21	5 minutes ago		demo-trials: demo1, demo-experiments: demo1	base-S	5 minutes ago

3. Double-click a trial to display a list of the components in the trial.

Name	Created	Trial component type	Tags	Last modified
TrainingJob	12 minutes ago	Training job		9 minutes ago

4. Double-click one of the components to open the **Describe Trial Component** tab.

Trial stages	Charts	Metrics	Parameters	Artifacts	Settings	Debugger	Trial Mappings												
TrainingJob Created 16 minutes ago			<table border="1"> <thead> <tr> <th>Name</th> <th>MetricID</th> <th>MinValue</th> <th>FinalValue</th> </tr> </thead> <tbody> <tr> <td>validationloss</td> <td>0.06006</td> <td>0.0691</td> <td>0.06797</td> </tr> <tr> <td>trainerror</td> <td>0.033</td> <td>0.07715</td> <td>0.033</td> </tr> </tbody> </table>	Name	MetricID	MinValue	FinalValue	validationloss	0.06006	0.0691	0.06797	trainerror	0.033	0.07715	0.033				
Name	MetricID	MinValue	FinalValue																
validationloss	0.06006	0.0691	0.06797																
trainerror	0.033	0.07715	0.033																

5. On the **Describe Trial Component** tab, choose any of the following column headings to see available information about each trial component:

- **Charts** – Build your own charts.
- **Metrics** – Metrics that are logged by a `Tracker` during a trial run.
- **Parameters** – Hyperparameter values and instance information.
- **Artifacts** – Amazon S3 bucket storage locations for the input dataset and the output model.
- **Amazon Settings** – Job name, ARN, status, creation time, training time, billable time, instance information, and others.
- **Debugger** – A list of debugger rules and any issues found.
- **Trial Mappings**

For information about comparing Experiments entities, see [View and Compare Amazon SageMaker Experiments, Trials, and Trial Components \(p. 1558\)](#).

## Compare Experiments, Trials, and Trial Components

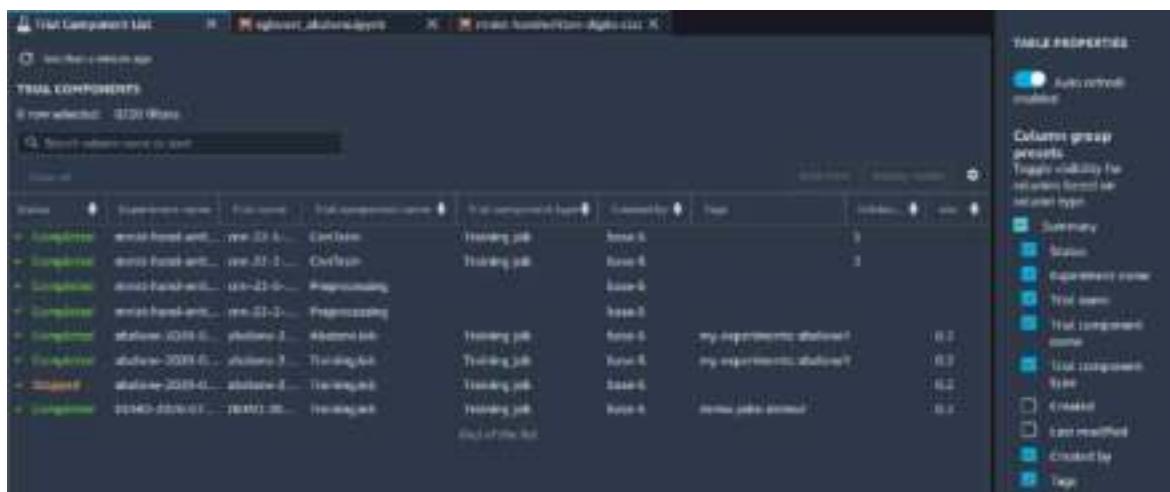

You can compare experiments, trials, and trial components by selecting the entities and opening them in the trial components list. The trial components list is referred to as the Studio Leaderboard. In the Leaderboard you can do the following:

- View detailed information about the entities
- Compare entities

- Stop a training job
- Deploy a model

## To compare experiments, trials, and trial components

1. In the left sidebar of SageMaker Studio, choose the **SageMaker Experiment List** icon (  ).
2. In the **Experiments** browser, choose either the experiment or trial list. For more information, see [View Experiments, Trials, and Trial Components \(p. 1559\)](#).
3. Choose the experiments or trials that you want to compare, right-click the selection, and then choose **Open in trial component list**. The Leaderboard opens and lists the associated Experiments entities as shown in the following screenshot.

The Leaderboard has a **TABLE PROPERTIES** pane on the right side. Use the **Settings** icon (  ) to open and close the pane. You can hide or display properties by category or by individual columns. When you display a chart, the pane changes to display chart properties.

For information on searching the Experiments entities, see [Search Experiments Using Amazon SageMaker Studio \(p. 1567\)](#).

## Track and Compare Tutorial

This tutorial demonstrates how to visually track and compare trials in a model training experiment using Amazon SageMaker Studio. The basis of the tutorial is the [MNIST Handwritten Digits Classification Experiment](#) notebook.

It is intended that this topic be viewed alongside Studio with the MNIST notebook open. As you run through the cells, the sections in this document highlight the relevant code and show you how to observe the results in Studio. Some of the code snippets have been edited for brevity.

To clean up the resources created by the notebook, see [Clean Up Amazon SageMaker Experiment Resources \(p. 1572\)](#).

For a tutorial that showcases additional features of Studio, see [Amazon SageMaker Studio Tour \(p. 51\)](#).

### Prerequisites

- A local copy of the [MNIST](#) example notebook and the companion [mnist.py](#) file. Both files are available from the `sagemaker_experiments/mnist-handwritten-digits-classification-experiment` folder in the [aws/amazon-sagemaker-examples](#) repository. To download the files, choose each link, right-click on the **Raw** button, and then choose **Save as**.
- An Amazon Web Services SSO or IAM account to sign-on to SageMaker Studio. For more information, see [Onboard to Amazon SageMaker Studio \(p. 35\)](#).

### Topics

- [Open the Notebook in Studio \(p. 1562\)](#)
- [Install the Experiments SDK and Import Modules \(p. 1562\)](#)
- [Transform and Track the Input Data \(p. 1563\)](#)
- [Create and Track an Experiment \(p. 1563\)](#)
- [Compare and Analyze Trials \(p. 1565\)](#)

## Open the Notebook in Studio

### To open the notebook

1. Sign-on to Studio.
2. In the left sidebar, choose the **File Browser** icon (  ).
3. At the top of the file browser pane, choose the **Up arrow** icon and then a **File Upload** dialog opens. Browse to and choose your local versions of the `mnist-handwritten-digits-classification-experiment.ipynb` and `mnist.py` files, and then choose **Open**.
4. The two files are listed in the file browser. Double-click the uploaded notebook file to open the notebook in a new tab.
5. At the top right of the notebook, make sure the kernel is **Python 3 (Data Science)**. If not, choose the current kernel name to open the **Select Kernel** dropdown. Choose **Python 3 (Data Science)** and then choose **Select**.

## Install the Experiments SDK and Import Modules

The [Amazon SageMaker Experiments Python SDK](#) is separate from the [Amazon SageMaker Python SDK](#), which comes preinstalled in SageMaker Studio. Run the first few cells in the notebook to install the Experiments SDK and import the Experiments modules. The relevant sections of the notebook cells are displayed below.

```
import sys
!{sys.executable} -m pip install sagemaker-experiments
```

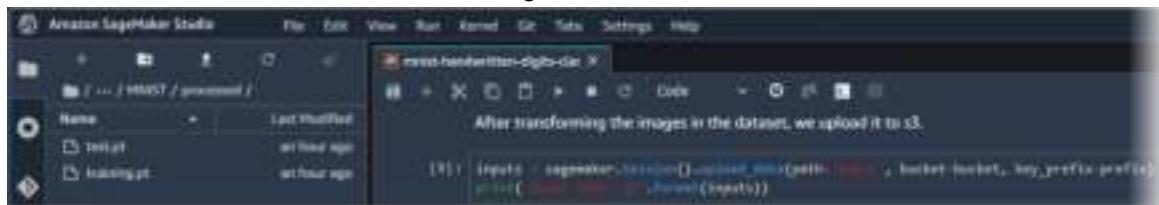

```
import sagemaker
from sagemaker import get_execution_role
from sagemaker.session import Session
from sagemaker.analytics import ExperimentAnalytics

from smexperiments.experiment import Experiment
from smexperiments.trial import Trial
from smexperiments.trial_component import TrialComponent
from smexperiments.tracker import Tracker
```

## Transform and Track the Input Data

The next few cells create an Amazon S3 bucket and a folder in the bucket named *mnist*. In Studio, the file browser displays the *mnist* folder. The input data is downloaded to the *mnist/MNIST/raw* folder, normalized, and then the transformed data is uploaded to the *mnist/MNIST/processed* folder. You can drill down into the *mnist* folder to display, but not open, the data files.

Your screen should look similar to the following:

The last cell in the **Dataset** section creates a **Tracker** for the transform job. The tracker logs the normalization parameters and the URI of the Amazon S3 bucket where the transformed dataset is stored. In a later section, we show how to find this information in Studio. In the next section, the tracker is used to track the experiment and trial runs.

```
with Tracker.create(display_name="Preprocessing", sagemaker_boto_client=sm) as tracker:  
    tracker.log_parameters(  
        {"normalization_mean": 0.1307,  
         "normalization_std": 0.3081,  
     })  
    tracker.log_input(name="mnist-dataset", media_type="s3/uri", value=inputs)
```

## Create and Track an Experiment

The following procedure creates and tracks an experiment to determine the effect of the model's `num_hidden_channel` hyperparameter. As part of the experiment, five trials are created inside a loop, one for each value of the `num_hidden_channel` hyperparameter. Later in the notebook, you'll compare the results of these five trials.

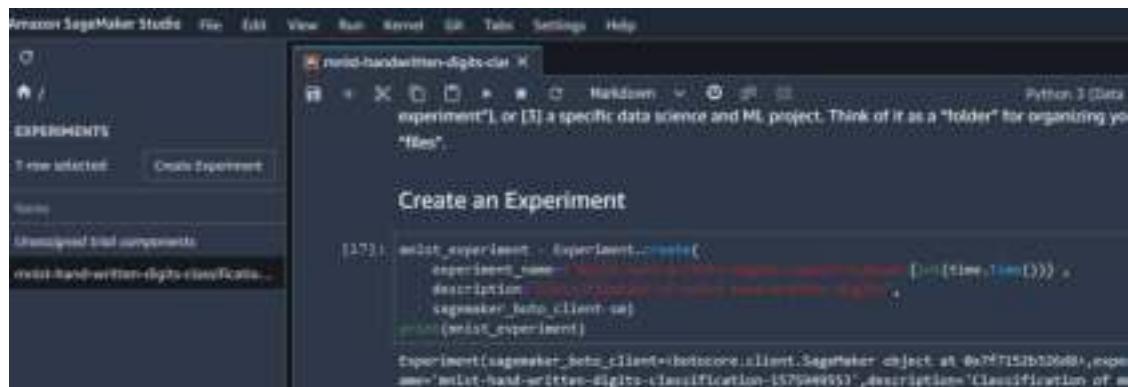

1. In the left sidebar of Studio, choose the **SageMaker Components and registries** icon (💡). In the dropdown menu, choose **Experiments and trials** to display the list of experiments in your account.
2. Run the following cell.

```
mnist_experiment = Experiment.create(  
    experiment_name=f"mnist-hand-written-digits-classification-{int(time.time())}",  
    description="Classification of mnist hand-written digits",  
    sagemaker_boto_client=sm)  
print(mnist_experiment)
```

Output:

```
Experiment(sagemaker_boto_client=<botocore.client.SageMaker object at 0x7f7152b326d8>,  
          experiment_name='mnist-hand-written-digits-classification-1575947870',  
          description='Classification of mnist hand-written digits',  
          experiment_arn='arn:aws:sagemaker:us-east-2:acct-id:experiment/mnist-hand-  
written-digits-classification-1575947870')
```

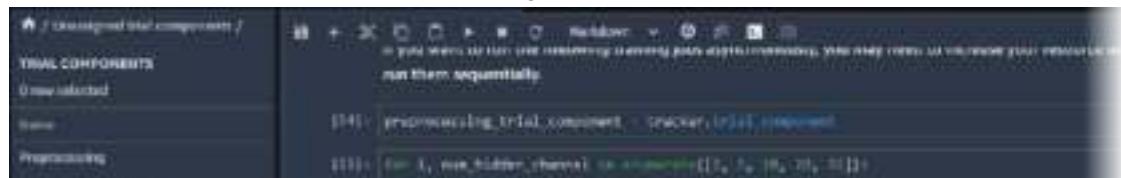

After the code runs, the experiments list contains an entry for the experiment. It might take a moment to display and you might have to refresh the experiments list. Your screen should look similar to the following:

- Run the following cell.

```
preprocessing_trial_component = tracker.trial_component
```

After the code runs, the experiments list contains an entry labeled **Unassigned trial components**. The trial component entry is the data preprocessing step previously created. Double-click the trial component for verification. The trial component isn't associated with an experiment at this time. Your screen should look similar to the following:

- Choose the Home icon in the navigation breadcrumb at the top on the experiments browser. From there, double-click on your experiment to display a list of the trials in the experiment.
- The following code creates trials for the experiment. Each trial trains a model using a different number for the `num_hidden_channel` hyperparameter. The preprocessing trial component is added to each trial for complete tracking (for example, for auditing purposes). The code also specifies definitions for the following metrics:
  - Train loss
  - Test loss
  - Test accuracy

The definitions tell SageMaker to capture those metrics from the algorithm's log output. The metrics are used later to evaluate and compare the models.

```
preprocessing_trial_component = tracker.trial_component

for i, num_hidden_channel in enumerate([2, 5, 10, 20, 32]):
    trial_name = f"cnn-training-job-{num_hidden_channel}-hidden-channels-{int(time.time())}"
    cnn_trial = Trial.create(
        trial_name=trial_name,
        experiment_name=mnist_experiment.experiment_name,
        sagemaker_boto_client=sm,
    )
    hidden_channel_trial_name_map[num_hidden_channel] = trial_name

    cnn_trial.add_trial_component(preprocessing_trial_component)
```

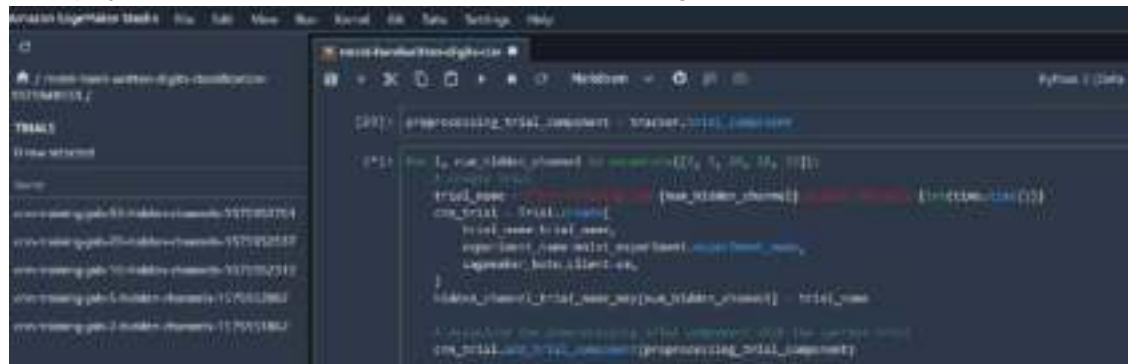

```

estimator = PyTorch(
    py_version='py3',
    framework_version='1.1.0',
    ...,
    hyperparameters={
        'hidden_channels': num_hidden_channel,
        ...
    },
    metric_definitions=[
        {'Name':'train:loss', 'Regex':'Train Loss: (.*)';'},
        {'Name':'test:loss', 'Regex':'Test Average loss: (.*)','},
        {'Name':'test:accuracy', 'Regex':'Test Accuracy: (.*)%'}
    ],
    enable_sagemaker_metrics=True,
)
cnn_training_job_name = "cnn-training-job-{}".format(int(time.time()))

estimator.fit(
    inputs={'training': inputs},
    job_name=cnn_training_job_name,
    experiment_config={
        "TrialName": cnn_trial.trial_name,
        "TrialComponentDisplayName": "Training",
    },
)

```

The trial list automatically updates as each training job runs. It takes a few minutes for each trial to be displayed. Your screen should look similar to the following:

## Compare and Analyze Trials

This section deviates from the notebook and shows you how to compare and analyze the trained models using the SageMaker Studio UI.

### To view the details of a trial

1. Double-click one of the trials to display a list of the trial components associated with the trial. There's a preprocessing job and training job for each trial. Double-click one of the components to open a new tab that displays information about each component.
2. Under **Trial stages**, choose **Preprocessing**. On the **Describe Trial Component** menu, choose **Parameters** to display the normalization parameters that were previously logged. Next, choose **Artifacts** to display the URI of the Amazon S3 bucket where the transformed dataset was stored.
3. Under **Trial stages**, choose **Training**. On the **Describe Trial Component** menu, choose the following items to display information about the training job trial component.

- **Metrics** – test:loss, test:accuracy, and train:loss
- **Parameters** – hyperparameter values and instance information
- **Artifacts** – Amazon S3 storage for the input dataset and the output model
- **Amazon Settings** – job name, ARN, status, creation time, training time, billable time, instance information, and others

### To view a list of trials ordered by test:accuracy

1. Choose the experiment name on the navigation breadcrumb above **TRIAL COMPONENTS** to display the trial list.
2. Choose all five trials. Hold down the CTRL/CMD key and select each trial. Right-click the selection and then choose **Open in trial component list**. A new tab opens that displays each trial and trial component.
3. If the **TABLE PROPERTIES** pane isn't open, choose the **Settings** icon (⚙) in the upper right corner to open it. Deselect everything except **Trial**, **Metrics**, and **Training job**. Choose the **Settings** icon to close the pane.
4. Choose the **test:accuracy** column header to sort the list by decreasing maximum test accuracy. Your screen should look similar to the following:

Trial	Status	test:accuracy	train:loss
cnn-training-job-10-hidden-c...	Completed	0.97	0.21908
cnn-training-job-20-hidden-c...	Completed	0.97	0.2272
cnn-training-job-3-hidden-ch...	Completed	0.97	0.157259
cnn-training-job-52-hidden-c...	Completed	0.97	0.101464
cnn-training-job-5-hidden-ch...	Completed	0.96	0.157844

**TABLE PROPERTIES**

Table properties are global and column level filters will override them. To access filters, click the ⚙ icon.

Auto refresh enabled

**Column group presets**  
Toggle visibility for columns based on column type.

Summary columns:

- Status
- Experiment
- Type
- Trial
- Trial component
- Created on
- Last modified

Metrics

Parameters

Tags

**Type filter**  
Toggle trial component type to apply filter.

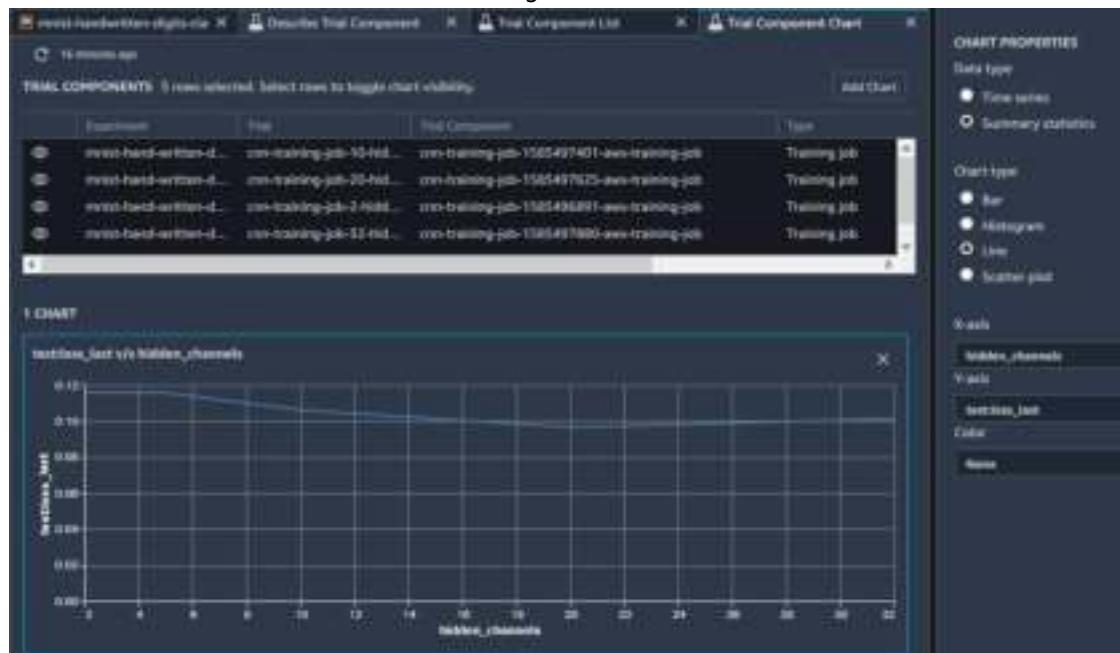

Training job

### To view a chart of test:loss versus num\_hidden\_channel

1. In the **TRIAL COMPONENTS** pane, choose all five trials and then choose **Add chart**. Select inside the chart area to open the preferences pane for **CHART PROPERTIES**.
2. In **CHART PROPERTIES**, choose the following:
  - **Data type - Summary statistics**
  - **Chart type - Line**
  - **X-axis - hidden-channels**
  - **Y-axis - test:loss\_last**

- Color - None

Your screen should look similar to the following:

## Search Experiments Using Amazon SageMaker Studio

You can search your experiments, trials, and trial components using the experiments browser. After choosing the entities, you can search on properties of these entities on the Amazon SageMaker Leaderboard.

### Topics

- [Search Experiments, Trials, and Trial Components \(p. 1567\)](#)
- [Search the SageMaker Studio Leaderboard \(p. 1568\)](#)
- [Search by Tag \(p. 1571\)](#)

## Search Experiments, Trials, and Trial Components

You can search and create multiple filters to display a subset of experiments, trials, and trial components in the experiments browser. After you search and filter your list, you can open the entities in the Leaderboard and search on additional properties.

### To search for experiments, trials, and trial components, and apply filters

For more information about the following steps, along with screenshots, see [Search the SageMaker Studio Leaderboard \(p. 1568\)](#).

1. In the experiments browser, navigate to the entity type you want to search for: experiment, trial, or trial component.
2. Place your cursor in the search box to display the list of column that are searchable.
3. Choose the column that you want to search on and one of the following dialog boxes opens that's specific to the column you chose:

- **String** – Enter a text string in the search dialog box that opens. Enter a string of at least three characters that's part of the component's property value. This filter limits the list to those components with a property value that contains the text string.
  - **Discrete values** – Choose one or more property values from the list. This filter limits the list to those components with a property value that matches at least one of the chosen values.
  - **Date** – Enter a date in **From Date** and **To Date**, or select the dates from the calendar. This filter limits the list to those components that were created or last modified in the specified data range.
  - **Tag** – In **Search tag key**, start entering the tag's key. A list of tag keys is filtered to only those keys with a name that starts with the text string that you enter. Choose the tag key that you want to search on from the list. In **Search tag value**, enter the complete tag value, and then choose **Apply**.
4. To create the filter, choose **Apply**.
  5. To apply additional filters, repeat the preceding steps. You can have a maximum of 20 filters. An entity must match all filters to be displayed.

## Search the SageMaker Studio Leaderboard

The Amazon SageMaker Studio trial components list is referred to as the Leaderboard. You can use the Leaderboard to compare your trials and experiments. The Leaderboard lists properties of the trials, such as the trial status, debugger status, tags, metrics, hyperparameters, and input and output artifacts.

You can search the Leaderboard to find specific trial components. You apply the results of a search to create a filter that displays only those components that satisfy the filter. You can apply up to 20 filters. A component is displayed only if it matches all filters. To remove a filter, choose the X that displays to the right of the filter.

### To search the Leaderboard and apply filters

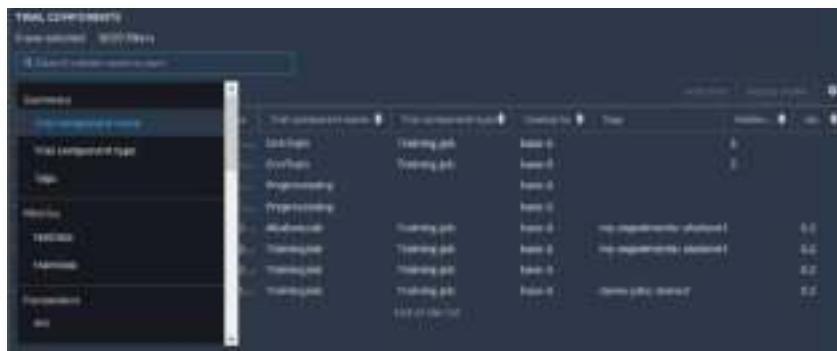

1. If the **TABLE PROPERTIES** pane isn't open in SageMaker Studio, choose the **Settings** icon ( ) in the upper-right corner to open it.
2. In the **Settings** pane, select the check boxes for the columns that you want to view, and then choose the **Settings** icon to close the pane.
3. Place your cursor in the **Search column name** box to display the following list of **TABLE PROPERTIES** column names that are searchable:

#### Summary section

- Trial component name
- Trial component type
- Created
- Last modified
- Created by
- Tags

#### Detail sections (all columns)

- Metrics
- Parameters
- Input artifacts
- Output artifacts

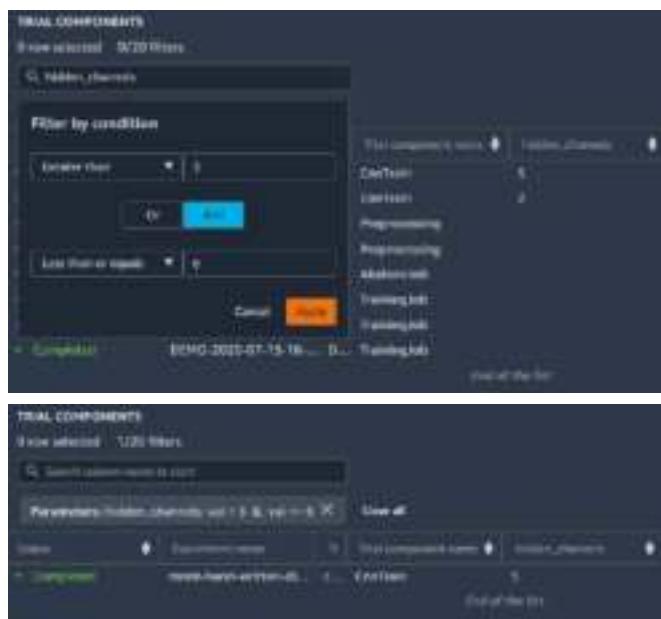

4. To limit the column names when you search the detail sections, start typing the column name. The list displays only those columns with a name that starts with the text string that you enter.
5. Choose the column that you want to search on. This opens a dialog that's specific to the type of data in that column.
6. Enter your search criteria in the dialog for the appropriate data type:
  - **String** – Enter a text string in the search dialog box that opens. Enter a string of at least three characters that's part of the component's property value. This filter limits the list to those components with a property value that contains the text string.

- **Discrete values** – Choose one or more of the property values from the list. This filter limits the list to those components with a property value that matches at least one of the chosen values. For the **Trial component type** column, **Others** matches components with no value in the column.

The screenshot shows the 'TRIAL COMPONENTS' search interface. At the top, there's a search bar with placeholder text 'Search components or tags'. Below it is a 'Filter by values' section with a dropdown menu set to 'Created by' and two options: 'Me' (selected) and 'Everyone else'. A 'Next' button is located at the bottom right of this section. To the right of the filter is a table titled 'Trial components table' with columns 'Trial component name', 'Type', and 'Last updated'. The table lists several entries, all of which are 'Training job' type and were last updated on '2020-07-01'. The first entry is 'abalone-2020-07-01...'. The table has a 'Edit filters' link at the bottom right.

- Date** – Enter a date in **From Date** and **To Date** or select the dates from the calendar. This filter limits the list to those components that were created or last modified in the specified data range.
- Created by** – Select **Me** or **Everyone else**. This filter limits the list to those components that were created by the currently signed-in user or everyone but the currently signed-in user.
- Tag** – Choose the tag to search. For more information, see [Search by Tag \(p. 1571\)](#).
- Detail columns** – Specify the conditions that the component's property value must satisfy.

This screenshot shows the same 'TRIAL COMPONENTS' search interface as above, but with a different filter applied. In the 'Filter by values' dropdown, 'Detail columns' is selected. The table below shows the same list of training jobs, but now includes an additional column 'Detail condition' which contains the value '1' for all rows. The table has a 'Edit filters' link at the bottom right.

7. To create the filter, choose **Apply**.
8. To apply additional filters, repeat the preceding steps. A component must match all filters to be displayed. You can have a maximum of 20 filters.

## Search by Tag

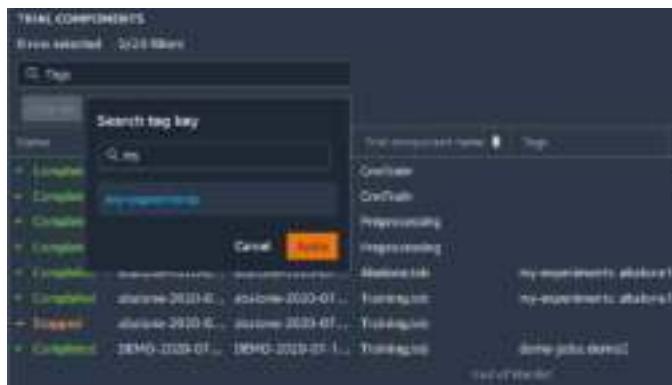

You can add searchable tags to experiments, trials, and trial components when the entities are created or afterwards using the [AddTags](#) API. A tag consists of a unique case-sensitive key and an optional value. Multiple tags can be added to an entity. You can add the same tag to multiple entities.

### To search by tag and apply filters

1. If the **TABLE PROPERTIES** pane isn't open in SageMaker Studio, choose the **Settings** icon (⚙) in the upper-right corner to open it.
2. In the **Settings** pane, select **Tags** if it isn't selected, and then choose the **Settings** icon to close the pane.
3. Place your cursor in the **Search column name** box and then choose **Tags**.

4. In **Search tag key**, start entering the tag's key. A list of tag keys displays only those keys with a name that starts with the text string that you enter.

5. Choose the tag key that you want to search on from the list.
6. In **Search tag value**, enter the complete tag value, and then choose **Apply**.

7. The trial component list displays only those components that have tags that match the key-value pair you chose.

8. To add more tag filters, repeat the previous steps. A tag must match all filters for the component to be displayed.

## Clean Up Amazon SageMaker Experiment Resources

To avoid incurring unnecessary charges, delete the Amazon SageMaker Experiment resources you no longer need. You can't delete Experiment resources through the SageMaker Management Console or the Amazon SageMaker Studio UI. This topic shows you how to clean up these resources using Boto3 and the Experiments SDK. For more information about the Experiments SDK, see [sagemaker-experiments](#).

To delete the experiment, you must delete all trials in the experiment. To delete a trial, you must remove all trial components from the trial. To delete a trial component, you must remove the component from all trials.

**Note**

Trial components can exist independent of trials and experiments. You do not have to delete them. If you want to reuse them, comment out `tc.delete()` in the code.

**Topics**

- [Clean Up Using the Experiments SDK \(p. 1573\)](#)
- [Clean Up Using the Python SDK \(Boto3\) \(p. 1573\)](#)

## Clean Up Using the Experiments SDK

### To clean up using the Experiments SDK

```
import sys
!{sys.executable} -m pip install sagemaker-experiments
```

```
import time

from smexperiments.experiment import Experiment
from smexperiments.trial import Trial
from smexperiments.trial_component import TrialComponent
```

### Define cleanup\_sme\_sdk

```
def cleanup_sme_sdk(experiment):
    for trial_summary in experiment.list_trials():
        trial = Trial.load(trial_name=trial_summary.trial_name)
        for trial_component_summary in trial.list_trial_components():
            tc = TrialComponent.load(
                trial_component_name=trial_component_summary.trial_component_name)
            trial.remove_trial_component(tc)
            try:
                # comment out to keep trial components
                tc.delete()
            except:
                # tc is associated with another trial
                continue
            # to prevent throttling
            time.sleep(.5)
        trial.delete()
        experiment_name = experiment.experiment_name
        experiment.delete()
        print(f"\nExperiment {experiment_name} deleted")
```

### Call cleanup\_sme\_sdk

```
experiment_to_cleanup = Experiment.load(
    # Use experiment name not display name
    experiment_name="experiment-name")

cleanup_sme_sdk(experiment_to_cleanup)
```

## Clean Up Using the Python SDK (Boto3)

### To clean up using Boto 3

```
import boto3
sm = boto3.Session().client('sagemaker')
```

### Define cleanup\_boto3

```
def cleanup_boto3(experiment_name):
    trials = sm.list_trials(ExperimentName=experiment_name)[ 'TrialSummaries' ]
    print('TrialNames:')
    for trial in trials:
        trial_name = trial['TrialName']
        print(f"\n{trial_name}")

        components_in_trial = sm.list_trial_components(TrialName=trial_name)
        print('\tTrialComponentNames:')
        for component in components_in_trial[ 'TrialComponentSummaries' ]:
            component_name = component['TrialComponentName']
            print(f"\t{component_name}")
            sm.disassociate_trial_component(TrialComponentName=component_name,
                TrialName=trial_name)
        try:
            # comment out to keep trial components
            sm.delete_trial_component(TrialComponentName=component_name)
        except:
            # component is associated with another trial
            continue
        # to prevent throttling
        time.sleep(.5)
    sm.delete_trial(TrialName=trial_name)
    sm.delete_experiment(ExperimentName=experiment_name)
    print(f"\nExperiment {experiment_name} deleted")
```

### Call cleanup\_boto3

```
# Use experiment name not display name
experiment_name = "experiment-name"
cleanup_boto3(experiment_name)
```

## Search Using the Amazon SageMaker Console and API

Developing a machine learning model typically requires extensive experimenting with different datasets, algorithms, and hyperparameter values. To manage up to thousands of machine learning model experiments, use the search capabilities in SageMaker.

You can use SageMaker search to:

- Organize, find, and evaluate training jobs using properties, hyperparameters, performance metrics, or any metadata.
- Find the best performing model by reviewing training job and model metrics, such as training loss or validation accuracy.
- Trace a model's lineage to the training job and its related resources, such as the training datasets.

This topic covers searching from the SageMaker console and the SageMaker API. For information on searching in Amazon SageMaker Studio, see [Search Experiments Using Studio \(p. 1567\)](#).

### Topics

- [Sample Notebooks for Managing ML Experiments \(p. 1575\)](#)
- [Organize, Find, and Evaluate Training Jobs \(Console\) \(p. 1575\)](#)
- [Find and Evaluate Training Jobs \(API\) \(p. 1577\)](#)
- [Verify the Datasets Used by Your Training Jobs \(p. 1578\)](#)

- [Trace Model Lineage \(p. 1578\)](#)

## Sample Notebooks for Managing ML Experiments

For a sample notebook that uses Amazon SageMaker model tracking capability to manage ML experiments, see [Managing ML Experimentation using Amazon SageMaker Model Tracking Capability](#).

For instructions on how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see [Use Amazon SageMaker Notebook Instances \(p. 120\)](#). After you have created a notebook instance and opened it, choose the **SageMaker Examples** tab to see a list of all of the SageMaker samples. The notebook for managing ML experiments is located in the **Advanced Functionality** section. To open a notebook, choose its **Use** tab, and choose **Create copy**. If you have questions, post them on the [Amazon Machine Learning Developer Forum](#).

## Organize, Find, and Evaluate Training Jobs (Console)

To organize training jobs, assign one or more tags to them.

To find a specific training job, model, or resource, use model tracking to search on keywords assigned to any searchable items. *Searchable items* include training jobs, models, hyperparameters, metadata, tags, and URLs. To refine your tracking results, you can search using multiple criteria.

To choose the best model for deployment, evaluate how all models performed against one or more metrics. You can use model tracking results to list, sort, and evaluate the performance of the models in your experiments.

### Topics

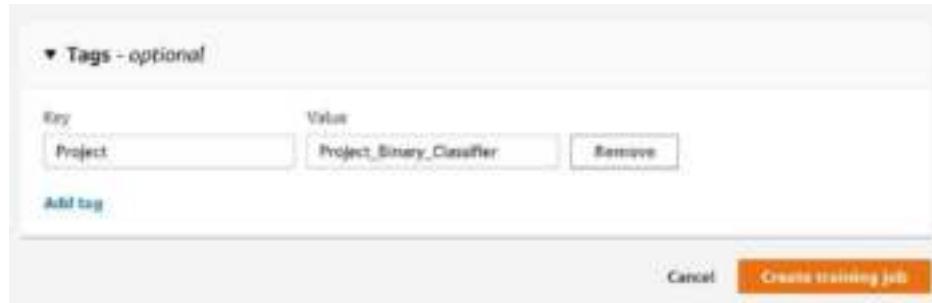

- [Use Tags to Track Training Jobs \(Console\) \(p. 1575\)](#)
- [Find Training Jobs \(Console\) \(p. 1576\)](#)
- [Evaluate Models \(Console\) \(p. 1576\)](#)

## Use Tags to Track Training Jobs (Console)

To group training jobs, create tags with descriptive keys and a value. For example, create tag keys for: project, owner, customer, and industry.

### Add tags to training jobs (console)

1. Open the [Amazon SageMaker console](#).
2. In the navigation pane, choose **Training jobs** and **Create training job**.
3. Scroll to the bottom of the page and enter a key and value for the tag.

4. To add another tag, choose **Add tag**, and add another key-value pair.

## Find Training Jobs (Console)

You can search for training jobs using a variety of job attributes. Note that some search parameters appear only if you have created a training job with that attribute. For example, **Tags** appears only if you have added a tag for a training job.

### To find training jobs (console)

1. Open the [Amazon SageMaker console](#).
2. In the navigation pane, choose **Search**.
3. Add **Parameters**.
  - a. In the search box, enter a parameter and choose a parameter type, for example **TrainingJobName**.
  - b. Choose a conditional operation. For numeric values, use operators such as **is equals to**, **lesser than**, or **or greater than**. For text-based values, use operators such as **equals to** or **contains**.
  - c. Enter a value for the parameter.
4. (Optional) To refine your search, add additional search criteria. Choose **Add row** and enter the parameter values.
5. Choose **Search**.

## Evaluate Models (Console)

To evaluate a model's performance, review its metadata, hyperparameters, and metrics. To highlight metrics, adjust the view to show only metrics and important hyperparameters.

### To evaluate a model (console)

1. Open the [Amazon SageMaker console](#).
2. In the navigation pane, choose **Search** and search for training jobs by specifying relevant parameters. The results are displayed in a table.

Results: Training jobs

HyperParameter mini_batch_size ▾	HyperParameter predictor_type ▾	Metric train:binary_f_beta ▾	Metric train:progress ▾	Metric train:objective_loss
300	binary_classifier	0.966639518737793	100	0.02381423674521
100	binary_classifier	0.9652714133262634	100	0.02350491285324
200	binary_classifier	0.9647442698478699	100	0.02325980737801

3. Open the preferences window by choosing the settings icon in the search results table.

4. To show or hide a hyperparameter or metric, turn it on or off by choosing **Hyperparameter or Metric**.
5. Make necessary changes, then choose **Update view**.
6. After viewing metrics and important hyperparameters, you can compare and contrast the result. Then, you can choose the best model to host or investigate the models that are performing poorly.

## Find and Evaluate Training Jobs (API)

To find and evaluate training jobs or to get suggestions for items used in experiments that are searchable, you can use the [Search API](#).

### Topics

- [Find Training Jobs \(API\) \(p. 1577\)](#)
- [Evaluate Models \(API\) \(p. 1577\)](#)
- [Get Suggestions for a Search \(API\) \(p. 1578\)](#)

## Find Training Jobs (API)

To find training jobs, create a search parameter using the `search_params` parameter. Then use the `search` function in the `smclient` subprocess in the Amazon SDK for Python (Boto3).

The following example shows how to use the [Search API](#) to find training jobs.

```
import boto3

search_params={
    "MaxResults": 10,
    "Resource": "TrainingJob",
    "SearchExpression": {
        "Filters": [
            {
                "Name": "Tags.Project",
                "Operator": "Equals",
                "Value": "Project_Binary_Classifier"
            }]
    },
    "SortBy": "Metrics.train:binary_classification_accuracy",
    "SortOrder": "Descending"
}

smclient = boto3.client(service_name='sagemaker')
results = smclient.search(**search_params)
```

## Evaluate Models (API)

To evaluate models, run a search as described in [Find Training Jobs \(API\) \(p. 1577\)](#), review model metrics, then, use the Amazon SDK for Python (Boto3) to create a table and plot it.

The following example shows how to evaluate models and to display the results in a table.

```
import pandas

headers=[ "Training Job Name", "Training Job Status", "Batch Size", "Binary Classification Accuracy"]
rows=[]
for result in results['Results']:
    trainingJob = result['TrainingJob']
    metrics = trainingJob['FinalMetricDataList']
```

```
rows.append([trainingJob['TrainingJobName'],
    trainingJob['TrainingJobStatus'],
    trainingJob['HyperParameters']['mini_batch_size'],
    metrics[[x['MetricName'] for x in
    metrics].index('train:binary_classification_accuracy')]['Value']
])

df = pandas.DataFrame(data=rows,columns=headers)

from IPython.display import display, HTMLdisplay(HTML(df.to_html()))
```

## Get Suggestions for a Search (API)

To get suggestions for a search, use the [GetSearchSuggestions API](#).

The following example for Amazon SDK for Python (Boto3) is a `get_search_suggestions` request for items containing `linear`.

```
search_suggestion_params={
    "Resource": "TrainingJob",
    "SuggestionQuery": {
        "PropertyNameQuery": {
            "PropertyNameHint": "linear"
        }
    }
}
```

The following is an example response for a `get_search_suggestions` request.

```
{
    'PropertyNameSuggestions': [{PropertyName': 'hyperparameters.linear_init_method'},
        {'PropertyName': 'hyperparameters.linear_init_value'},
        {'PropertyName': 'hyperparameters.linear_init_sigma'},
        {'PropertyName': 'hyperparameters.linear_lr'},
        {'PropertyName': 'hyperparameters.linear_wd'}]
}
```

After getting search suggestions, you can use one of the property names in a search.

## Verify the Datasets Used by Your Training Jobs

You can use model tracking capability to verify which datasets were used in training, where holdout datasets were used, and other details about training jobs. For example, use model tracking capability to verify that a specific dataset was used in a training job for an audit or to verify compliance.

To check whether a specific dataset was used in a training job, you search for the URL to its location in Amazon Simple Storage Service (Amazon S3). Model tracking capability returns the training jobs that used the dataset that you specify. If your search doesn't return the dataset (the result is empty), the dataset wasn't used in a training job. An empty result confirms, for example, that a holdout dataset wasn't used.

## Trace Model Lineage

You can use model tracking capability to get information about the lineage of training jobs and the model resources that were used for them, including the dataset, algorithm, hyperparameters, and metrics. For example, if you find that the performance of a hosted model has declined, you can review its training job and the resources it used to determine what's causing the problem.

## Topics

- [Trace Model Lineage \(Console\) \(p. 1579\)](#)
- [Trace Model Lineage \(API\) \(p. 1579\)](#)

## Trace Model Lineage (Console)

### To trace a model's lineage (console)

1. Open the [Amazon SageMaker console](#).
2. In the navigation pane, choose **Endpoints**, and choose the relevant endpoint.
3. Scroll to the **Endpoint configuration settings** section. This section lists all of the model versions deployed at the endpoint, with a hyperlink to the training job that created each.

## Trace Model Lineage (API)

To trace a model's lineage, get the model's name, then use it to search for training jobs.

The following example shows how to trace a model's lineage using the API.

```
# Get the name of model deployed at endpoint
endpoint_config = smclient.describe_endpoint_config(EndpointConfigName=endpointName)
model_name = endpoint_config['ProductionVariants'][0]['ModelName']

# Get the model's name
model = smclient.describe_model(ModelName=model_name)

# Search the training job by the location of model artifacts in Amazon S3
search_params={
    "MaxResults": 1,
    "Resource": "TrainingJob",
    "SearchExpression": {
        "Filters": [
            {
                "Name": "ModelArtifacts.S3ModelArtifacts",
                "Operator": "Equals",
                "Value": model['PrimaryContainer']['ModelDataUrl']
            }]
    }
}
results = smclient.search(**search_params)
```

After finding the training job, you can review the resources used to train the model.

# Amazon SageMaker Debugger

Debug, monitor, and profile training jobs in real time, detect non-converging conditions, optimize resource utilization by eliminating bottlenecks, improve training time, and reduce costs of your machine learning models using Amazon SageMaker Debugger.

## Amazon SageMaker Debugger Features

A machine learning (ML) training job can have problems such as system bottlenecks, overfitting, saturated activation functions, and vanishing gradients, which can compromise model performance.

SageMaker Debugger profiles and debugs training jobs to help resolve such problems and improve your ML model's compute resource utilization and performance. Debugger offers tools to send alerts when training anomalies are found, take actions against the problems, and identify the root cause of them by visualizing collected metrics and tensors.

SageMaker Debugger supports Apache MXNet, TensorFlow, PyTorch, and XGBoost. For more information about available frameworks and versions, see [Supported Frameworks and Algorithms \(p. 1581\)](#).

The high-level Debugger workflow is as follows:

1. Configure a SageMaker training job with Debugger.
  - Configure using the SageMaker [Estimator API \(for Python SDK\)](#).
  - Configure using the SageMaker [CreateTrainingJob request \(for Boto3 or CLI\)](#).
  - Configure [custom training containers \(p. 1672\)](#) with Debugger.
2. Start a training job and monitor training issues in real time.
  - [SageMaker Studio Debugger dashboards in Studio Experiments and trials \(p. 1685\)](#).
  - [List of Debugger Built-in Rules \(p. 1626\)](#).
3. Get alerts and take prompt actions against the training issues.
  - Receive texts and emails and stop training jobs when training issues are found using [Debugger Built-in Actions for Rules \(p. 1676\)](#).
  - Set up your own actions using [Amazon CloudWatch Events and Amazon Lambda \(p. 1680\)](#).
4. Receive training reports, suggestions to fix the issues, and insights into your training jobs.
  - [Studio Debugger Insights dashboard for deep learning frameworks](#)
  - [Deep learning framework profiling report](#)
  - [SageMaker XGBoost training report](#)
5. Explore deep analysis of the training issues and bottlenecks.
  - For profiling training jobs, see [Analyze Data Using the SMDebug Client Library \(p. 1724\)](#).
  - For debugging model parameters, see [Visualize Debugger Output Tensors in TensorBoard \(p. 1681\)](#).
6. Fix the issues, considering the suggestions provided by Debugger, and repeat steps 1–5 until you optimize your model and achieve target accuracy.

The SageMaker Debugger developer guide walks you through the following topics.

## Supported Frameworks and Algorithms

The following table shows SageMaker machine learning frameworks and algorithms supported by Debugger.

SageMaker frameworks and algorithms	Monitoring system bottlenecks	Profiling deep learning framework operations	Debugging model parameters
TensorFlow	All <a href="#">Amazon Deep learning containers</a>	Amazon TensorFlow deep learning containers 2.3.1 or later	<a href="#">Amazon TensorFlow deep learning containers</a> 1.15.4 or later
PyTorch		Amazon PyTorch deep learning containers 1.6.0 or later	<a href="#">Amazon PyTorch deep learning containers</a> 1.5.0 or later
MXNet		-	<a href="#">Amazon MXNet deep learning containers</a> 1.6.0 or later
XGBoost	1.0-1, 1.2-1	-	1.0-1, 1.2-1
SageMaker generic estimator	SageMaker built-in algorithms using image URIs  <a href="#">Custom training containers (p. 1672)</a> (with the Amazon deep learning container images, public Docker images, or your own Docker images)	-  <a href="#">Custom training containers (p. 1672)</a> (available for TensorFlow, PyTorch, MXNet, and XGBoost with manual hook registration)	<a href="#">Custom training containers (p. 1672)</a> (available for TensorFlow, PyTorch, MXNet, and XGBoost with manual hook registration)

- **Monitoring system bottlenecks** – Monitor the system utilization rate for resources such as CPU, GPU, memories, network, and data I/O metrics. This is a framework and model agnostic feature and available for any training jobs in SageMaker.

- **Profiling deep learning framework operations** – Profile the deep learning operations of the TensorFlow and PyTorch frameworks, such as step durations, data loaders, forward and backward operations, Python profiling metrics, and framework-specific metrics.
- **Debugging model parameters** – Track and debug model parameters, such as weights, gradients, biases, and scalar values of your training job. Available deep learning frameworks are Apache MXNet, TensorFlow, PyTorch, and XGBoost.

If the framework or algorithm that you want to train and debug is not listed in the table, go to the [Amazon Discussion Forum](#) and leave feedback on SageMaker Debugger.

## Use Debugger with Custom Training Containers

Bring your training containers to SageMaker and gain insights into your training jobs using Debugger. Maximize your work efficiency by optimizing your model on Amazon EC2 instances using the monitoring and debugging features.

For more information about how to build your training container with the SMDebug client library, push it to the Amazon Elastic Container Registry (Amazon ECR), and monitor and debug, see [Use Debugger with Custom Training Containers \(p. 1672\)](#).

## Debugger Open-Source GitHub Repositories

Debugger APIs are provided through the SageMaker Python SDK and designed to construct Debugger hook and rule configurations for the SageMaker [CreateTrainingJob](#) and [DescribeTrainingJob](#) API operations. The SMDebug client library provides tools to register *hooks* and access the training data through its *trial* feature, all through its flexible and powerful API operations. It supports the machine learning frameworks TensorFlow, PyTorch, MXNet, and XGBoost on Python 3.6 and later.

For direct resources about the Debugger and SMDebug API operations, see the following links:

- [The Amazon SageMaker Python SDK documentation](#)
- [The Amazon SageMaker Debugger APIs](#)
- [The SMDebug open source client library](#)
- [The SMDebug PyPI](#)

If you use the SDK for Java to conduct SageMaker training jobs and want to configure Debugger APIs, see the following references:

- [Amazon SageMaker Debugger API Operations \(p. 1737\)](#)
- [Configure Debugger Using Amazon SageMaker API \(p. 1615\)](#)

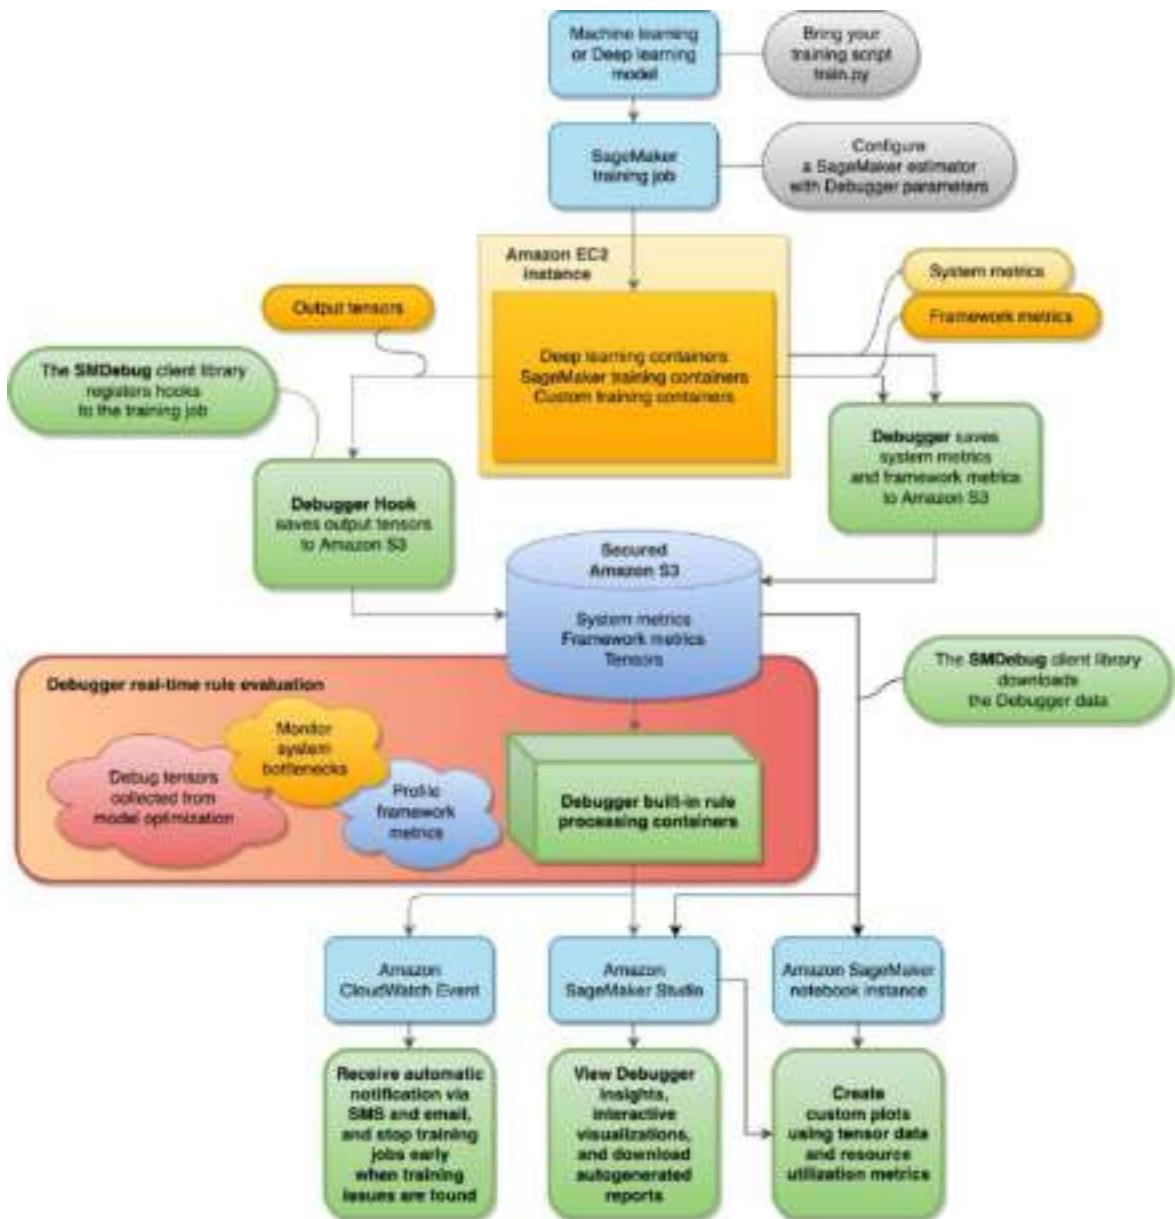

## Amazon SageMaker Debugger Architecture

This topic walks you through a high-level overview of the Amazon SageMaker Debugger workflow.

Debugger supports profiling functionality for *performance optimization* to identify computation issues, such as system bottlenecks and underutilization, and to help optimize hardware resource utilization at scale.

Debugger's debugging functionality for *model optimization* is about analyzing non-converging training issues that can arise while minimizing the loss functions using optimization algorithms, such as gradient descent and its variations.

The following diagram shows the architecture of SageMaker Debugger. The blocks with bold boundary lines are what Debugger manages to analyze your training job.

Debugger stores the following data from your training jobs in your secured Amazon S3 bucket:

- **System metrics** – Hardware resource utilization data, such as CPU, GPU, CPU and GPU memory, network, and data input and output (I/O) metrics.
- **Framework metrics** – Metrics to track each framework operation per call or sampling, such as convolutional layer operations in the forward pass, batch normalization operations in the backward pass, data loader processes between steps, and gradient descent algorithm operations to calculate and update the loss function.
- **Output tensors** – Collections of scalars and model parameters that are continuously updated during the forward and backward passes while training ML models. The output tensors include scalar values (accuracy and loss) and matrices (weights, gradients, input layers, and output layers).

#### Note

By default, Debugger monitors and debugs SageMaker training jobs without any Debugger-specific parameters configured in SageMaker estimators. Debugger collects system metrics

every 500 milliseconds and basic output tensors (scalar outputs such as loss and accuracy) every 500 steps. It also runs the `ProfilerReport` rule to analyze the system metrics and aggregate the Studio Debugger insights dashboard and a profiling report. Debugger saves the output data in your secured Amazon S3 bucket.

The Debugger built-in rules run on processing containers, which are designed to evaluate machine learning models by processing the training data collected in your S3 bucket (see [Process Data and Evaluate Models](#)). The built-in rules are fully managed by Debugger. You can also create your own rules customized to your model to watch for any issues you want to monitor.

See the following topics for best practices to improve the performance of your model using SageMaker Debugger.

## Get Started with Debugger Tutorials

The following topics walk you through tutorials from the basics to advanced use cases of monitoring, profiling, and debugging SageMaker training jobs using Debugger. Explore the Debugger features and learn how you can debug and improve your machine learning models efficiently by using Debugger.

### Topics

- [Debugger Tutorial Videos \(p. 1584\)](#)
- [Debugger Example Notebooks \(p. 1585\)](#)
- [Debugger Advanced Demos and Visualization \(p. 1587\)](#)

## Debugger Tutorial Videos

The following videos provide a tour of Amazon SageMaker Debugger capabilities using SageMaker Studio and SageMaker notebook instances.

### Topics

- [Analyze, Detect, and Get Alerted on Problems with Training Runs Using Amazon SageMaker Debugger \(p. 1584\)](#)
- [Debug Models with Amazon SageMaker Debugger in Studio \(p. 1584\)](#)
- [Deep Dive on Amazon SageMaker Debugger and SageMaker Model Monitor \(p. 1585\)](#)

## Analyze, Detect, and Get Alerted on Problems with Training Runs Using Amazon SageMaker Debugger

*Emily Webber, Amazon Machine Learning Specialist | Length: 13 minutes 54 seconds*

This tutorial video gives you a tour of Amazon SageMaker Debugger to capture, debug, and visualize model output data from a training model with MXNet. Learn how Amazon SageMaker Debugger makes the training process transparent by automatically capturing metrics, analyzing training runs, and detecting problems.

### [Analyze, Detect, and Get Alerted on Problems with Training Runs Using Amazon SageMaker Debugger](#)

You can find the example notebook in this video at [Visualizing Debugging Tensors of MXNet training](#) in the [Amazon SageMaker Examples](#) GitHub repository.

## Debug Models with Amazon SageMaker Debugger in Studio

*Julien Simon, Amazon Technical Evangelist | Length: 14 minutes 17 seconds*

This tutorial video demonstrates how to use Amazon SageMaker Debugger to capture and inspect debugging information from a training model. The example training model used in this video is a simple convolutional neural network (CNN) based on Keras with the TensorFlow backend. SageMaker in a TensorFlow framework and Debugger enable you to build an estimator directly using the training script and debug the training job.

### [Debug Models with Amazon SageMaker Debugger \(part 1\)](#)

You can find the example notebook in the video in [this Studio Demo repository](#) provided by the author. You need to clone the `debugger.ipynb` notebook file and the `mnist_keras_tf.py` training script to your SageMaker Studio or a SageMaker notebook instance. After you clone the two files, specify the path `keras_script_path` to the `mnist_keras_tf.py` file inside the `debugger.ipynb` notebook. For example, if you cloned the two files in the same directory, set it as `keras_script_path = "mnist_keras_tf.py"`.

## [Deep Dive on Amazon SageMaker Debugger and SageMaker Model Monitor](#)

*Julien Simon, Amazon Technical Evangelist | Length: 44 minutes 34 seconds*

This video session explores advanced features of Debugger and SageMaker Model Monitor that help boost productivity and the quality of your models. First, this video shows how to detect and fix training issues, visualize tensors, and improve models with Debugger. Next, at 22:41, the video shows how to monitor models in production and identify prediction issues such as missing features or data drift using SageMaker Model Monitor. Finally, it offers cost optimization tips to help you make the most of your machine learning budget.

### [Debug Models with Debugger \(part 2\)](#)

You can find the example notebook in the video in [this Amazon Dev Days 2020 repository](#) offered by the author.

## Debugger Example Notebooks

SageMaker Debugger example notebooks are provided in the [aws/amazon-sagemaker-examples](#) repository. The Debugger example notebooks walk you through basic to advanced use cases of debugging and profiling training jobs.

We recommend that you run the example notebooks on SageMaker Studio or a SageMaker Notebook instance because most of the examples are designed for training jobs in the SageMaker ecosystem, including Amazon EC2, Amazon S3, and Amazon SageMaker Python SDK.

To clone the example repository to SageMaker Studio, follow the instructions at [Amazon SageMaker Studio Tour](#).

To find the examples in a SageMaker Notebook instance, follow the instructions at [SageMaker Notebook Instance Example Notebooks](#).

### Important

To use the new Debugger features, you need to upgrade the SageMaker Python SDK and the SMDebug client library. In your iPython kernel, Jupyter Notebook, or JupyterLab environment, run the following code to install the latest versions of the libraries and restart the kernel.

```
import sys
import IPython
!{sys.executable} -m pip install -U sagemaker smdebug
IPython.Application.instance().kernel.do_shutdown(True)
```

## [Debugger Example Notebooks for Profiling Training Jobs](#)

The following list shows Debugger example notebooks introducing Debugger's adaptability to monitor and profile training jobs for various machine learning models, datasets, and frameworks.

Notebook Title	Framework	Model	Dataset	Description
<a href="#">Amazon SageMaker Debugger Profiling Data Analysis</a>	TensorFlow	Keras ResNet50	Cifar-10	This notebook provides an introduction to interactive analysis of profiled data captured by SageMaker Debugger. Explore the full functionality of the SMDebug interactive analysis tools.
<a href="#">Profile machine learning training with Amazon SageMaker Debugger</a>	TensorFlow	1-D Convolutional Neural Network	IMDB dataset	Profile a TensorFlow 1-D CNN for sentiment analysis of IMDB data that consists of movie reviews labeled as having positive or negative sentiment. Explore the Studio Debugger insights and Debugger profiling report.
<a href="#">Profiling TensorFlow ResNet model training with various distributed training settings</a>	TensorFlow	ResNet50	Cifar-10	Run TensorFlow training jobs with various distributed training settings, monitor system resource utilization, and profile model performance using Debugger.
<a href="#">Profiling PyTorch ResNet model training with various distributed training settings</a>	PyTorch	ResNet50	Cifar-10	Run PyTorch training jobs with various distributed training settings, monitor system resource utilization, and profile model performance using Debugger.

## Debugger Example Notebooks for Analyzing Model Parameters

The following list shows Debugger example notebooks introducing Debugger's adaptability to debug training jobs for various machine learning models, datasets, and frameworks.

Notebook Title	Framework	Model	Dataset	Description
<a href="#">Amazon SageMaker Debugger - Use built-in rule</a>	TensorFlow	Convolutional Neural Network	MNIST	Use the Amazon SageMaker Debugger built-in rules for debugging a TensorFlow model.
<a href="#">Amazon SageMaker Debugger - Tensorflow 2.1</a>	TensorFlow	ResNet50	Cifar-10	Use the Amazon SageMaker Debugger hook configuration and built-in rules for debugging

Notebook Title	Framework	Model	Dataset	Description
				a model with the Tensorflow 2.1 framework.
<a href="#">Visualizing Debugging Tensors of MXNet training</a>	MXNet	Gluon Convolutional Neural Network	Fashion MNIST	Run a training job and configure SageMaker Debugger to store all tensors from this job, then visualize those tensors in a notebook.
<a href="#">Enable Spot Training with Amazon SageMaker Debugger</a>	MXNet	Gluon Convolutional Neural Network	Fashion MNIST	Learn how Debugger collects tensor data from a training job on a spot instance, and how to use the Debugger built-in rules with managed spot training.
<a href="#">Debugging XGBoost Training Jobs with Amazon SageMaker Debugger Using Rules</a>	XGBoost	XGBoost Regression	Abalone	Learn how to use the Debugger hook and built-in rules for collecting and visualizing tensor data from an XGBoost regression model, such as loss values, features, and SHAP values.

To find advanced visualizations of model parameters and use cases, see the next topic at [Debugger Advanced Demos and Visualization \(p. 1587\)](#).

## Debugger Advanced Demos and Visualization

The following demos walk you through advanced use cases and visualization scripts using Debugger.

### Topics

- [Train and Tune Your Models with Amazon SageMaker Experiments and Debugger \(p. 1587\)](#)
- [Using SageMaker Debugger to Monitor a Convolutional Autoencoder Model Training \(p. 1590\)](#)
- [Using SageMaker Debugger to Monitor Attentions in BERT Model Training \(p. 1590\)](#)
- [Using SageMaker Debugger to Visualize Class Activation Maps in Convolutional Neural Networks \(CNNs\) \(p. 1593\)](#)

## Train and Tune Your Models with Amazon SageMaker Experiments and Debugger

*Dr. Nathalie Rauschmayr, Amazon Applied Scientist | Length: 49 minutes 26 seconds*

### [Train and Prune Models with SageMaker Experiments and Debugger](#)

Find out how Amazon SageMaker Experiments and Debugger can simplify the management of your training jobs. Amazon SageMaker Debugger provides transparent visibility into training jobs and saves training metrics into your Amazon S3 bucket. SageMaker Experiments enables you to call the training information as *trials* through SageMaker Studio and supports visualization of the training job. This helps you keep model quality high while reducing less important parameters based on importance rank.

This video demonstrates a *model pruning* technique that makes pre-trained ResNet50 and AlexNet models lighter and affordable while keeping high standards for model accuracy.

SageMaker Estimator trains those algorithms supplied from the PyTorch model zoo in an Amazon Deep Learning Containers with PyTorch framework, and Debugger extracts training metrics from the training process.

The video also demonstrates how to set up a Debugger custom rule to watch the accuracy of a pruned model, to trigger an Amazon CloudWatch event and an Amazon Lambda function when the accuracy hits a threshold, and to automatically stop the pruning process to avoid redundant iterations.

Learning objectives are as follows:

- Learn how to use SageMaker to accelerate ML model training and improve model quality.
- Understand how to manage training iterations with SageMaker Experiments by automatically capturing input parameters, configurations, and results.
- Discover how Debugger makes the training process transparent by automatically capturing real-time tensor data from metrics such as weights, gradients, and activation outputs of convolutional neural networks.
- Use CloudWatch to trigger Lambda when Debugger catches issues.
- Master the SageMaker training process using SageMaker Experiments and Debugger.

You can find the notebooks and training scripts used in this video from [SageMaker Debugger PyTorch Iterative Model Pruning](#).

The following image shows how the iterative model pruning process reduces the size of AlexNet by cutting out the 100 least significant filters based on importance rank evaluated by activation outputs and gradients.

The pruning process reduced the initial 50 million parameters to 18 million. It also reduced the estimated model size from 201 MB to 73 MB.

**Pruning iteration: 0**

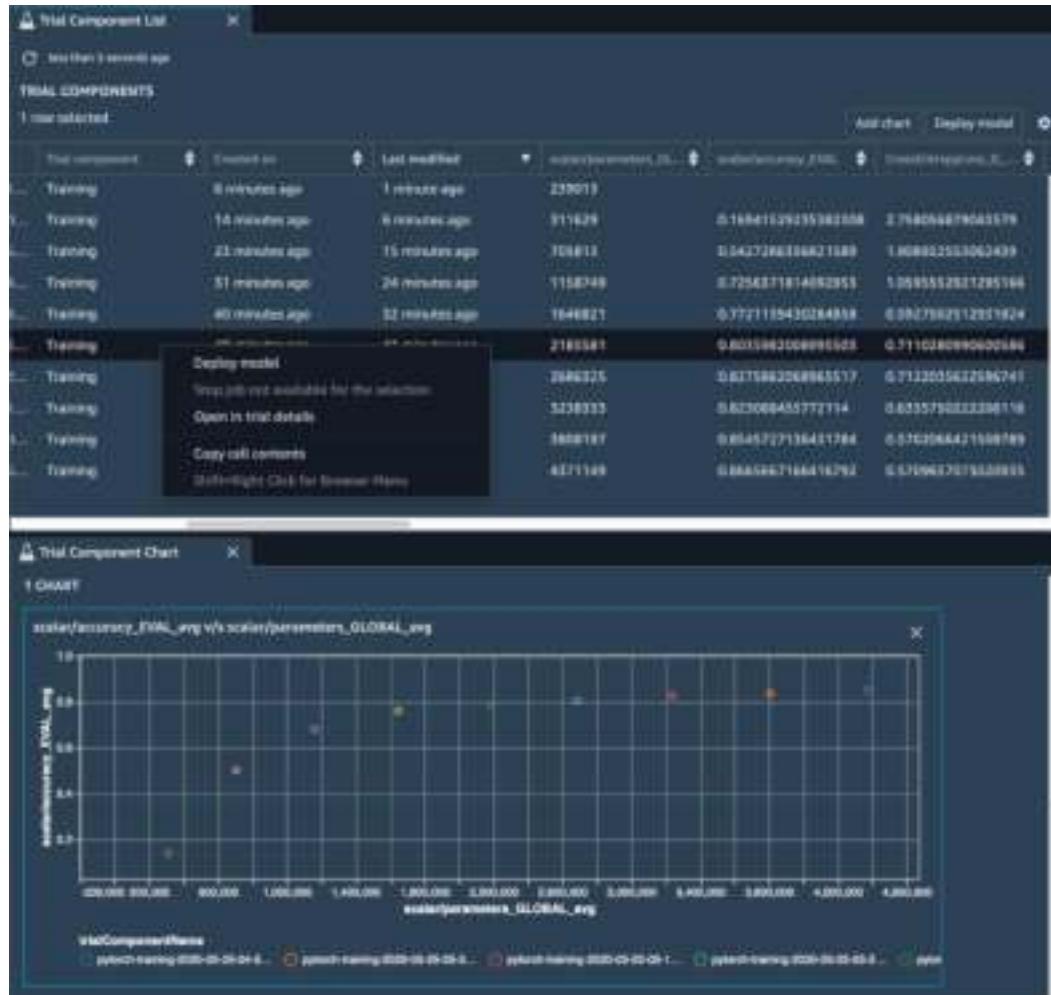

Layer (type)	Output Shape	Param #
Conv2d-1	[1, 58, 55, 55]	21,112
ReLU-2	[1, 58, 55, 55]	0
MaxPool2d-3	[1, 58, 27, 27]	0
Conv2d-4	[1, 166, 27, 27]	240,866
ReLU-5	[1, 166, 27, 27]	0
MaxPool2d-6	[1, 166, 13, 13]	0

ReLU-17	[1, 4096]	0
Dropout-18	[1, 4096]	0
Linear-19	[1, 4096]	16,781,312
ReLU-20	[1, 4096]	0
Linear-21	[1, 101]	413,797
<hr/>		
Total params:	50,883,321	
Trainable params:	50,883,321	
Non-trainable params:	0	

---

Input size (MB):	0.57
Forward/backward pass size (MB):	7.27
Params size (MB):	194.18
Estimated Total Size (MB):	201.95

---

You also need to track model accuracy, and the following image shows how you can plot the model pruning process to visualize changes in model accuracy based on the number of parameters in SageMaker Studio.

In SageMaker Studio, choose the **Experiments** tab, select a list of tensors saved by Debugger from the pruning process, and then compose a **Trial Component List** panel. Select all ten iterations and then choose **Add chart** to create a **Trial Component Chart**. After you decide on a model to deploy, choose the trial component and choose a menu to perform an action or choose **Deploy model**.

#### Note

To deploy a model through SageMaker Studio using the following notebook example, add a line at the end of the `train` function in the `train.py` script.

```
# In the train.py script, look for the train function in line 58.
def train(epochs, batch_size, learning_rate):
    ...
    print('acc:{:.4f}'.format(correct/total))
    hook.save_scalar("accuracy", correct/total, sm_metric=True)

    # Add the following code to line 128 of the train.py script to save the pruned
    # models
    # under the current SageMaker Studio model directory
    torch.save(model.state_dict(), os.environ['SM_MODEL_DIR'] + '/model.pt')
```

## Using SageMaker Debugger to Monitor a Convolutional Autoencoder Model Training

This notebook demonstrates how SageMaker Debugger visualizes tensors from an unsupervised (or self-supervised) learning process on a MNIST image dataset of handwritten numbers.

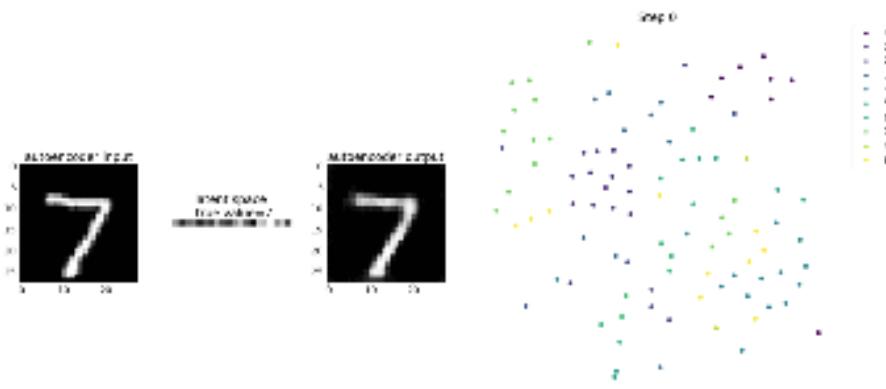

The training model in this notebook is a convolutional autoencoder with the MXNet framework. The convolutional autoencoder has a bottleneck-shaped convolutional neural network that consists of an encoder part and a decoder part.

The encoder in this example has two convolution layers to produce compressed representation (latent variables) of the input images. In this case, the encoder produces a latent variable of size (1, 20) from an original input image of size (28, 28) and significantly reduces the size of data for training by 40 times.

The decoder has two *deconvolutional* layers and ensures that the latent variables preserve key information by reconstructing output images.

The convolutional encoder powers clustering algorithms with smaller input data size and the performance of clustering algorithms such as k-means, k-NN, and t-Distributed Stochastic Neighbor Embedding (t-SNE).

This notebook example demonstrates how to visualize the latent variables using Debugger, as shown in the following animation. It also demonstrates how the t-SNE algorithm classifies the latent variables into ten clusters and projects them into a two-dimensional space. The scatter plot color scheme on the right side of the image reflects the true values to show how well the BERT model and t-SNE algorithm organize the latent variables into the clusters.

## Using SageMaker Debugger to Monitor Attentions in BERT Model Training

Bidirectional Encode Representations from Transformers (BERT) is a language representation model. As the name of model reflects, the BERT model builds on *transfer learning* and the *Transformer model* for natural language processing (NLP).

The BERT model is pre-trained on unsupervised tasks such as predicting missing words in a sentence or predicting the next sentence that naturally follows a previous sentence. The training data contains 3.3 billion words (tokens) of English text, from sources such as Wikipedia and electronic books. For a simple example, the BERT model can give a high *attention* to appropriate verb tokens or pronoun tokens from a subject token.

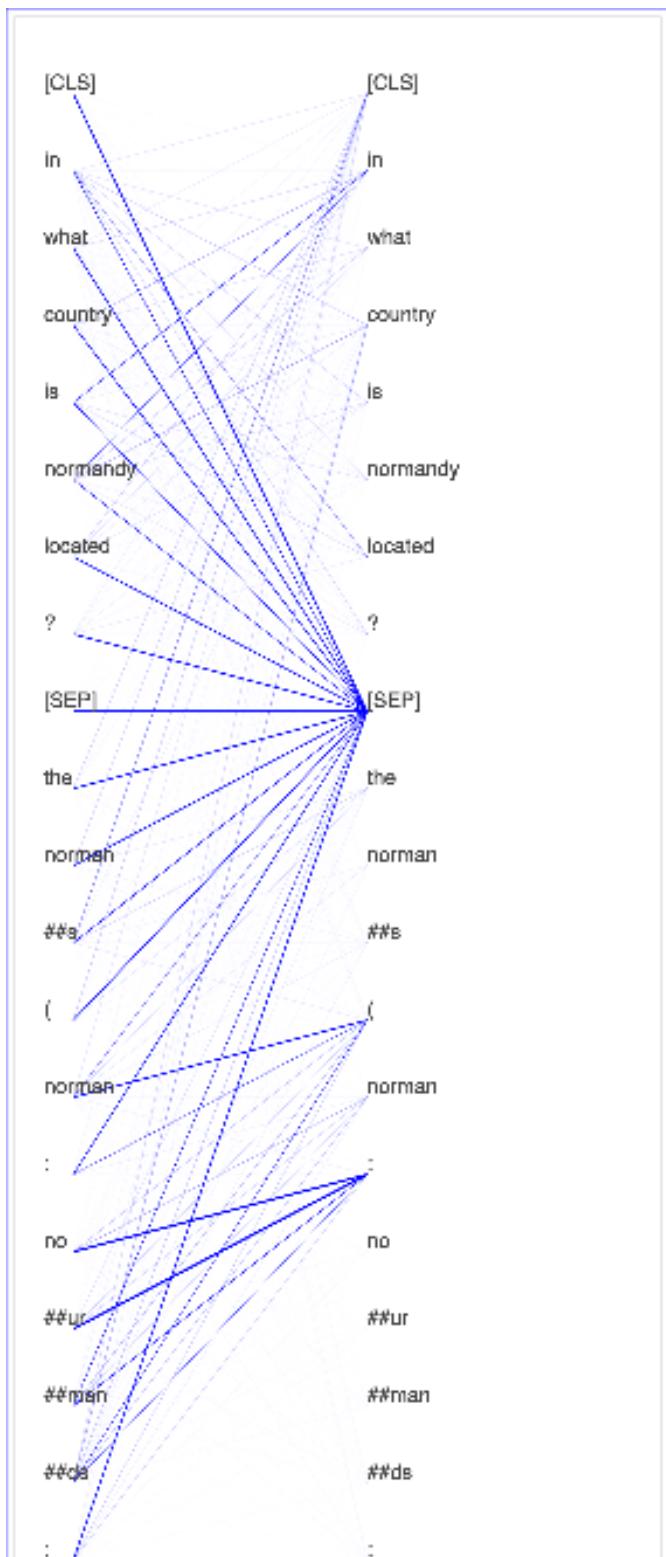

The pre-trained BERT model can be fine-tuned with an additional output layer to achieve state-of-the-art model training in NLP tasks, such as automated responses to questions, text classification, and many others.

Debugger collects tensors from the fine-tuning process. In the context of NLP, the weight of neurons is called *attention*.

This notebook demonstrates how to use the [pre-trained BERT model from the GluonNLP model zoo](#) on the Stanford Question and Answering dataset and how to set up SageMaker Debugger to monitor the training job.

Plotting *attention scores* and individual neurons in the query and key vectors can help to identify causes of incorrect model predictions. With SageMaker Debugger, you can retrieve the tensors and plot the *attention-head view* in real time as training progresses and understand what the model is learning.

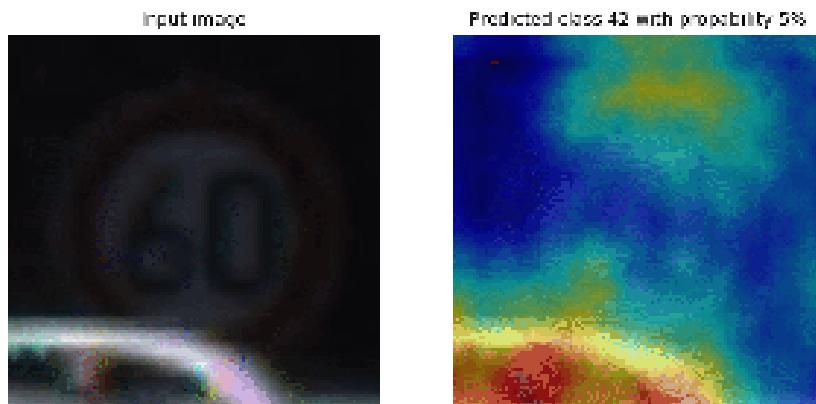

The following animation shows the attention scores of the first 20 input tokens for ten iterations in the training job provided in the notebook example.

## Using SageMaker Debugger to Visualize Class Activation Maps in Convolutional Neural Networks (CNNs)

This notebook demonstrates how to use SageMaker Debugger to plot class activation maps for image detection and classification in convolutional neural networks (CNNs). In deep learning, a *convolutional neural network (CNN or ConvNet)* is a class of deep neural networks, most commonly applied to analyzing visual imagery. One of the applications that adopts the class activation maps is self-driving cars, which require instantaneous detection and classification of images such as traffic signs, roads, and obstacles.

In this notebook, the PyTorch ResNet model is trained on [the German Traffic Sign Dataset](#), which contains more than 40 classes of traffic-related objects and more than 50,000 images in total.

During the training process, SageMaker Debugger collects tensors to plot the class activation maps in real time. As shown in the animated image, the class activation map (also called as a *saliency map*) highlights regions with high activation in red color.

Using tensors captured by Debugger, you can visualize how the activation map evolves during the model training. The model starts by detecting the edge on the lower-left corner at the beginning of the training job. As the training progresses, the focus shifts to the center and detects the speed limit sign, and the model successfully predicts the input image as Class 3, which is a class of speed limit 60km/h signs, with a 97% confidence level.

## Configure Debugger Using Amazon SageMaker Python SDK

To configure Debugger, use [Amazon SageMaker Python SDK](#) and specify Debugger-specific parameters while constructing SageMaker estimators. There are three parameters you need to configure: `profiler_config`, `debugger_hook_config`, and `rules`.

### Note

By default, Debugger monitors and debugs SageMaker training jobs without any Debugger-specific parameters configured in SageMaker estimators. Debugger collects system metrics every 500 milliseconds and basic output tensors (scalar outputs such as loss and accuracy) every 500 steps. It also runs the `ProfilerReport` rule to analyze the system metrics and aggregate the Studio Debugger insights dashboard and a profiling report. Debugger saves the output data in your secured S3 bucket.

### Important

To use the new Debugger features, you need to upgrade the SageMaker Python SDK and the SMDebug client library. In your iPython kernel, Jupyter Notebook, or JupyterLab environment, run the following code to install the latest versions of the libraries and restart the kernel.

```
import sys
import IPython
!{sys.executable} -m pip install -U sagemaker smdebug
IPython.Application.instance().kernel.do_shutdown(True)
```

## Construct a SageMaker Estimator with Debugger

The following example codes show how to construct a SageMaker estimator with the Debugger-specific parameters depending on a framework of your choice. Throughout the documentation in the following topics, you can find more information about how to configure the Debugger-specific parameters that you can mix and match as you want.

### Note

The following example codes are not directly executable. You need to proceed to the next sections and configure the Debugger-specific parameters.

### TensorFlow

To access the deep profiling feature for TensorFlow, currently you need to specify the latest Amazon deep learning container images with CUDA 11. For example, you must specify the specific image URI as shown in the following example code:

```
# An example of constructing a SageMaker TensorFlow estimator
import boto3
import sagemaker
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import ProfilerConfig, DebuggerHookConfig, Rule, ProfilerRule,
    rule_configs

session=boto3.session.Session()
region=session.region_name

profiler_config=ProfilerConfig(...)
debugger_hook_config=DebuggerHookConfig(...)
rules=[
    Rule.sagemaker(rule_configs.built_in_rule()),
    ProfilerRule.sagemaker(rule_configs.BuiltInRule())
]

estimator=TensorFlow(
    entry_point="directory/to/your_training_script.py",
    role=sagemaker.get_execution_role(),
    base_job_name="debugger-demo",
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    image_uri=f"763104351884.dkr.ecr.{region}.amazonaws.com/tensorflow-training:2.3.1-
gpu-py37-cu110-ubuntu18.04"

    # Debugger-specific parameters
    profiler_config=profiler_config,
    debugger_hook_config=debugger_hook_config,
    rules=rules
)

estimator.fit(wait=False)
```

## PyTorch

To access the deep profiling feature for PyTorch, currently you need to specify the latest Amazon deep learning container images with CUDA 11. For example, you must specify the specific image URI as shown in the following example code:

```
# An example of constructing a SageMaker PyTorch estimator
import boto3
import sagemaker
from sagemaker.pytorch import PyTorch
from sagemaker.debugger import ProfilerConfig, DebuggerHookConfig, Rule, ProfilerRule,
rule_configs

session=boto3.session.Session()
region=session.region_name

profiler_config=ProfilerConfig(...)
debugger_hook_config=DebuggerHookConfig(...)
rules=[
    Rule.sagemaker(rule_configs.built_in_rule()),
    ProfilerRule.sagemaker(rule_configs.BuiltInRule())
]

estimator=PyTorch(
    entry_point="directory/to/your_training_script.py",
    role=sagemaker.get_execution_role(),
    base_job_name="debugger-demo",
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    image_uri=f"763104351884.dkr.ecr.{region}.amazonaws.com/pytorch-training:1.6.0-gpu-
py36-cu110-ubuntu18.04",

    # Debugger-specific parameters
    profiler_config=profiler_config,
    debugger_hook_config=debugger_hook_config,
    rules=rules
)

estimator.fit(wait=False)
```

## MXNet

```
# An example of constructing a SageMaker MXNet estimator
import sagemaker
from sagemaker.mxnet import MXNet
from sagemaker.debugger import ProfilerConfig, DebuggerHookConfig, Rule, ProfilerRule,
rule_configs

profiler_config=ProfilerConfig(...)
debugger_hook_config=DebuggerHookConfig(...)
rules=[
    Rule.sagemaker(rule_configs.built_in_rule()),
    ProfilerRule.sagemaker(rule_configs.BuiltInRule())
]

estimator=MXNet(
    entry_point="directory/to/your_training_script.py",
    role=sagemaker.get_execution_role(),
    base_job_name="debugger-demo",
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    framework_version="1.7.0",
    py_version="py37",
```

```

        # Debugger-specific parameters
        profiler_config=profiler_config,
        debugger_hook_config=debugger_hook_config,
        rules=rules
    )

estimator.fit(wait=False)

```

#### **Note**

For MXNet, when configuring the `profiler_config` parameter, you can only configure for system monitoring. Profiling framework metrics is not supported for MXNet.

#### XGBoost

```

# An example of constructing a SageMaker XGBoost estimator
import sagemaker
from sagemaker.xgboost.estimator import XGBoost
from sagemaker.debugger import ProfilerConfig, DebuggerHookConfig, Rule, ProfilerRule,
rule_configs

profiler_config=ProfilerConfig(...)
debugger_hook_config=DebuggerHookConfig(...)
rules=[
    Rule.sagemaker(rule_configs.built_in_rule()),
    ProfilerRule.sagemaker(rule_configs.BuiltInRule())
]

estimator=XGBoost(
    entry_point="directory/to/your_training_script.py",
    role=sagemaker.get_execution_role(),
    base_job_name="debugger-demo",
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    framework_version="1.2-1",

    # Debugger-specific parameters
    profiler_config=profiler_config,
    debugger_hook_config=debugger_hook_config,
    rules=rules
)

estimator.fit(wait=False)

```

#### **Note**

For XGBoost, when configuring the `profiler_config` parameter, you can only configure for system monitoring. Profiling framework metrics is not supported for XGBoost.

#### Generic estimator

```

# An example of constructing a SageMaker generic estimator using the XGBoost algorithm
base_image
import boto3
import sagemaker
from sagemaker.estimator import Estimator
from sagemaker import image_uris
from sagemaker.debugger import ProfilerConfig, DebuggerHookConfig, Rule, ProfilerRule,
rule_configs

profiler_config=ProfilerConfig(...)
debugger_hook_config=DebuggerHookConfig(...)
rules=[
    Rule.sagemaker(rule_configs.built_in_rule()),
    ProfilerRule.sagemaker(rule_configs.BuiltInRule())
]

```

```
]

region=boto3.Session().region_name
xgboost_container=sagemaker.image_uris.retrieve("xgboost", region, "1.2-1")

estimator=Estimator(
    role=sagemaker.get_execution_role(),
    image_uri=xgboost_container,
    base_job_name="debugger-demo",
    instance_count=1,
    instance_type="ml.m5.2xlarge",

    # Debugger-specific parameters
    profiler_config=profiler_config,
    debugger_hook_config=debugger_hook_config,
    rules=rules
)
estimator.fit(wait=False)
```

Where you configure the following parameters:

- **profiler\_config** parameter – Configure Debugger to collect system metrics and framework metrics from your training job and save into your secured S3 bucket URI or local machine. To learn how to configure the **profiler\_config** parameter, see [Configure Debugger Monitoring Hardware System Resource Utilization \(p. 1598\)](#) and [Configure Debugger Framework Profiling \(p. 1598\)](#).
- **debugger\_hook\_config** parameter – Configure Debugger to collect output tensors from your training job and save into your secured S3 bucket URI or local machine. To learn how to configure the **debugger\_hook\_config** parameter, see [Configure Debugger Hook to Save Tensors \(p. 1602\)](#).
- **rules** parameter – Configure this parameter to enable Debugger built-in rules that you want to run in parallel. The rules automatically analyze your training job and find training issues. The ProfilerReport rule saves the Debugger profiling reports in your secured S3 bucket URI. To learn how to configure the **rules** parameter, see [Configure Debugger Built-in Rules \(p. 1608\)](#).

#### Note

Debugger securely saves output data in subfolders of your default S3 bucket. For example, the format of the default S3 bucket URI is `s3://sagemaker-<region>-<12digit_account_id>/<base-job-name>/<debugger-subfolders>/`. There are three subfolders created by Debugger: `debug-output`, `profiler-output`, and `rule-output`. You can also retrieve the default S3 bucket URLs using the [SageMaker estimator classmethods \(p. 1614\)](#).

See the following topics to find out how to configure the Debugger-specific parameters in detail.

#### Topics

## Configure Debugger Monitoring Hardware System Resource Utilization

To adjust Debugger system monitoring time intervals, use the `ProfilerConfig` API operation to create a parameter object while constructing a SageMaker framework or generic estimator depending on your preference.

### Note

By default, for all SageMaker training jobs, Debugger collects hardware system utilization data from Amazon EC2 instances every 500 milliseconds for system monitoring, without any Debugger-specific parameters specified in SageMaker estimators.

Debugger saves the system metrics in a default S3 bucket. The format of the default S3 bucket URI is `s3://sagemaker-<region>-<12digit_account_id>/<training-job-name>/profiler-output/`.

The following example code shows how to set up the `profiler_config` parameter with a system monitoring time interval of 1000 milliseconds.

```
from sagemaker.debugger import ProfilerConfig

profiler_config=ProfilerConfig(
    system_monitor_interval_millis=1000
)
```

- `system_monitor_interval_millis` (int) – Specify the monitoring intervals in milliseconds to record system metrics. Available values are 100, 200, 500, 1000 (1 second), 5000 (5 seconds), and 60000 (1 minute) milliseconds. The default value is 500 milliseconds.

To see the progress of system monitoring, see [Open Amazon SageMaker Debugger Insights Dashboard \(p. 1686\)](#).

## Configure Debugger Framework Profiling

To enable Debugger framework profiling, configure the `framework_profile_params` parameter when you construct an estimator. Debugger framework profiling collects framework metrics, such as data from initialization stage, data loader processes, Python operators of deep learning frameworks and training scripts, detailed profiling within and between steps, with cProfile or Pyinstrument options. Using the `FrameworkProfile` class, you can configure custom framework profiling options.

### Note

Before getting started with Debugger framework profiling, verify that the framework used to build your model is supported by Debugger for framework profiling. For more information, see [Supported Frameworks and Algorithms \(p. 1581\)](#).

Debugger saves the framework metrics in a default S3 bucket. The format of the default S3 bucket URI is `s3://sagemaker-<region>-<12digit_account_id>/<training-job-name>/profiler-output/`.

## Start a Training Job with the Default System Monitoring and Framework Profiling

The following example code is the simplest `profiler_config` parameter setting to start the default system monitoring and the default framework profiling. The `FrameworkProfile` class in the following example code initiates the default framework profiling when a training job starts. Debugger framework profiling includes the following options: detailed profiling, data loader profiling, and Python profiling.

```
from sagemaker.debugger import ProfilerConfig, FrameworkProfile
```

```
profiler_config=ProfilerConfig(  
    framework_profile_params=FrameworkProfile()  
)
```

With this `profiler_config` parameter configuration, Debugger calls the default settings of monitoring and profiling. Debugger monitors system metrics every 500 milliseconds; profiles the fifth step with the detailed profiling option; the seventh step with the data loader profiling option; and the ninth, tenth, and eleventh steps with the Python profiling option.

To find available profiling configuration options, the default parameter settings, and examples of how to configure them, see [Start a Training Job with the Default System Monitoring and Customized Framework Profiling with Different Profiling Options \(p. 1600\)](#) and [SageMaker Debugger APIs – FrameworkProfile](#) in the [Amazon SageMaker Python SDK](#).

If you want to change the system monitoring interval and enable the default framework profiling, you can specify the `system_monitor_interval_millis` parameter explicitly with the `framework_profile_params` parameter. For example, to monitor every 1000 milliseconds and enable the default framework profiling, use the following example code.

```
from sagemaker.debugger import ProfilerConfig, FrameworkProfile  
  
profiler_config=ProfilerConfig(  
    system_monitor_interval_millis=1000,  
    framework_profile_params=FrameworkProfile()  
)
```

For more information about the `FrameworkProfile` class, see [SageMaker Debugger APIs – FrameworkProfile](#) in the [Amazon SageMaker Python SDK](#).

## Start a Training Job with the Default System Monitoring and Customized Framework Profiling for Target Steps or a Target Time Range

If you want to specify target steps or target time intervals to profile your training job, you need to specify parameters for the `FrameworkProfile` class. The following code examples show how to specify the target ranges for profiling along with system monitoring.

- **For a target step range**

With the following example configuration, Debugger monitors the entire training job every 500 milliseconds (the default monitoring) and profiles a target step range from step 5 to step 15 (for 10 steps).

```
from sagemaker.debugger import ProfilerConfig, FrameworkProfile  
  
profiler_config=ProfilerConfig(  
    framework_profile_params=FrameworkProfile(start_step=5, num_steps=10)  
)
```

With the following example configuration, Debugger monitors the entire training job every 1000 milliseconds and profiles a target step range from step 5 to step 15 (for 10 steps).

```
from sagemaker.debugger import ProfilerConfig, FrameworkProfile  
  
profiler_config=ProfilerConfig(  
    system_monitor_interval_millis=1000,  
    framework_profile_params=FrameworkProfile(start_step=5, num_steps=10)  
)
```

- **For a target time range**

With the following example configuration, Debugger monitors the entire training job every 500 milliseconds (the default monitoring) and profiles a target time range from the current Unix time for 600 seconds.

```
import time
from sagemaker.debugger import ProfilerConfig, FrameworkProfile

profiler_config=ProfilerConfig(
    framework_profile_params=FrameworkProfile(start_unix_time=int(time.time()),
                                                duration=600)
)
```

With the following example configuration, Debugger monitors the entire training job every 1000 milliseconds and profiles a target time range from the current Unix time for 600 seconds.

```
import time
from sagemaker.debugger import ProfilerConfig, FrameworkProfile

profiler_config=ProfilerConfig(
    system_monitor_interval_millis=1000,
    framework_profile_params=FrameworkProfile(start_unix_time=int(time.time()),
                                                duration=600)
)
```

The framework profiling is performed for all of the profiling options at the target step or time range.

To find more information about available profiling options, see [SageMaker Debugger APIs – FrameworkProfile](#) in the [Amazon SageMaker Python SDK](#).

The next section shows you how to script the available profiling options.

## Start a Training Job with the Default System Monitoring and Customized Framework Profiling with Different Profiling Options

You can use the following profiling configuration classes to manage the framework profiling options:

- [DetailedProfilingConfig](#) – Specify a target step or time range to profile framework operations using the native framework profilers (TensorFlow profiler and PyTorch profiler). For example, if using TensorFlow, the Debugger hooks enable the TensorFlow profiler to collect TensorFlow-specific framework metrics. Detailed profiling enables you to profile all framework operators at a pre-step (before the first step), within steps, and between steps of a training job.

**Note**

Detailed profiling might significantly increase GPU memory consumption. We do not recommend enabling detailed profiling for more than a couple of steps.

- [DataloaderProfilingConfig](#) – Specify a target step or time range to profile deep learning framework data loader processes. Debugger collects every data loader event of the frameworks.

**Note**

Data loader profiling might lower the training performance while collecting information from data loaders. We don't recommend enabling data loader profiling for more than a couple of steps.

Debugger is preconfigured to annotate data loader processes only for the Amazon deep learning containers. Debugger cannot profile data loader processes from any other custom or external training containers.

- [PythonProfilingConfig](#) – Specify a target step or time range to profile Python functions. You can also choose between two Python profilers: cProfile and Pyinstrument.

- *cProfile* – The standard Python profiler. *cProfile* collects information for every Python operator called during training. With *cProfile*, Debugger saves cumulative time and annotation for each function call, providing complete detail about Python functions. In deep learning, for example, the most frequently called functions might be the convolutional filters and backward pass operators, and *cProfile* profiles every single of them. For the *cProfile* option, you can further select a timer option: total time, CPU time, and off-CPU time. While you can profile every function call executing on processors (both CPU and GPU) in CPU time, you can also identify I/O or network bottlenecks with the off-CPU time option. The default is total time, and Debugger profiles both CPU and off-CPU time. With *cProfile*, you are able to drill down to every single functions when analyzing the profile data.
- *Pyinstrument* – *Pyinstrument* is a low-overhead Python profiler that works based on sampling. With the *Pyinstrument* option, Debugger samples profiling events every millisecond. Because *Pyinstrument* measures elapsed wall-clock time instead of CPU time, the *Pyinstrument* option can be a better choice over the *cProfile* option for reducing profiling noise (filtering out irrelevant function calls that are cumulatively fast) and capturing operators that are actually compute intensive (cumulatively slow) for training your model. With *Pyinstrument*, you are able to see a tree of function calls and better understand the structure and root cause of the slowness.

**Note**

Enabling Python profiling might slow down the overall training time. *cProfile* profiles the most frequently called Python operators at every call, so the processing time on profiling increases with respect to the number of calls. For *Pyinstrument*, the cumulative profiling time increases with respect to time because of its sampling mechanism.

The following example configuration shows the full structure when you use the different profiling options with specified values.

```
import time
from sagemaker.debugger import (ProfilerConfig,
                                 FrameworkProfile,
                                 DetailedProfilingConfig,
                                 DataloaderProfilingConfig,
                                 PythonProfilingConfig,
                                 PythonProfiler, cProfileTimer)

profiler_config=ProfilerConfig(
    system_monitor_interval_millis=500,
    framework_profile_params=FrameworkProfile(
        detailed_profiling_config=DetailedProfilingConfig(
            start_step=5,
            num_steps=1
        ),
        dataloader_profiling_config=DataloaderProfilingConfig(
            start_step=7,
            num_steps=1
        ),
        python_profiling_config=PythonProfilingConfig(
            start_step=9,
            num_steps=1,
            python_profiler=PythonProfiler.CPROFILE,
            cprofile_timer=cProfileTimer.TOTAL_TIME
        )
    )
)
```

For more information about available profiling options, see [DetailedProfilingConfig](#), [DataloaderProfilingConfig](#), and [PythonProfilingConfig](#) in the [Amazon SageMaker Python SDK](#).

## Updating Debugger System Monitoring and Framework Profiling Configuration while a Training Job is Running

If you want to enable or update the Debugger monitoring and profiling configuration for a training job that is currently running, use the following SageMaker estimator extension methods:

- To enable Debugger system monitoring for a running training job and receive a Debugger profiling report, use the following:

```
estimator.enable_default_profiling()
```

When you use the `enable_default_profiling` method, Debugger initiates the default system monitoring and the `ProfileReport` built-in rule, which generates a comprehensive profiling report at the end of the training job. This method can be called only if the current training job is running without both Debugger monitoring and profiling.

For more information, see [estimator.enable\\_default\\_profiling](#) in the [Amazon SageMaker Python SDK](#).

- To enable Debugger built-in rules, system monitoring, and framework profiling with customizable configuration parameters, use the following:

```
estimator.update_profiler(  
    rules=[ProfilerRule.sagemaker(rule_configs.BuiltInRule()),  
          system_monitor_interval_millis=500,  
          framework_profile_params=FrameworkProfile()  
)
```

For more information, see [estimator.update\\_profiler](#) in the [Amazon SageMaker Python SDK](#).

## Configure Debugger Hook to Save Tensors

*Tensors* are data collections of updated parameters from the backward and forward pass of each training iteration, and Debugger collects output tensors to analyze the state of a training job. The Amazon SageMaker Debugger `CollectionConfig` and `DebuggerHookConfig` API operations provide methods for grouping tensors into *collections* and saving them to a target S3 bucket.

### Note

By default, for all SageMaker training jobs, Debugger collects loss and accuracy output scalars from the training jobs every 500 steps, without any Debugger-specific parameters specified in SageMaker estimators. Debugger saves the output data in a default S3 bucket. The format of the default S3 bucket URI is `s3://sagemaker-<region>-<12digit_account_id>/<training-job-name>/debug-output/`.

While constructing a SageMaker estimator, enable Debugger by specifying the hook configuration parameter, `debugger_hook_config`. The following steps include examples of how to set up the `debugger_hook_config` using the `CollectionConfig` and `DebuggerHookConfig` API operations to pull tensors out of your training jobs and save them. If you use [Debugger-supported Amazon containers for zero script change](#), you can simply run the training job without changing your training script. You can also use Debugger for training jobs running in any other [Debugger-supported Amazon containers with script mode](#), making minimal changes to your training script.

### Configure Debugger Tensor Collections Using the CollectionConfig API Operation

Use the `CollectionConfig` API operation to configure tensor collections. Debugger provides pre-built tensor collections that cover a variety of regular expressions (regex) of parameters if using Debugger-

supported deep learning frameworks and machine learning algorithms. As shown in the following example code, add the built-in tensor collections you want to debug.

```
from sagemaker.debugger import CollectionConfig

collection_configs=[
    CollectionConfig(name="weights"),
    CollectionConfig(name="gradients")
]
```

The preceding collections set up the Debugger hook to save the tensors every 500 steps based on the default "save\_interval" value.

For a full list of available Debugger built-in collections, see [Debugger Built-in Collections](#).

If you want to customize the built-in collections, such as changing the save intervals and tensor regex, use the following `CollectionConfig` template to adjust parameters.

```
from sagemaker.debugger import CollectionConfig

collection_configs=[
    CollectionConfig(
        name="tensor_collection",
        parameters={
            "key_1": "value_1",
            "key_2": "value_2",
            ...
            "key_n": "value_n"
        }
    )
]
```

For more information about available parameter keys, see [CollectionConfig](#) in the [Amazon SageMaker Python SDK](#). For example, the following code example shows how you can adjust the save intervals of the "losses" tensor collection at different phases of training: save loss every 100 steps in training phase and validation loss every 10 steps in validation phase.

```
from sagemaker.debugger import CollectionConfig

collection_configs=[
    CollectionConfig(
        name="losses",
        parameters={
            "train.save_interval": "100",
            "eval.save_interval": "10"
        }
    )
]
```

**Tip**

This tensor collection configuration object can be used for both [DebuggerHookConfig](#) and [Rule](#) API operations.

## Configure Debugger Hook to Save Tensors

Use the [DebuggerHookConfig](#) class to create a `debugger_hook_config` object using the `collection_configs` object you created in the previous step.

```
from sagemaker.debugger import DebuggerHookConfig
```

```
    debugger_hook_config=DebuggerHookConfig(  
        collection_configs=collection_configs  
)
```

Debugger saves the model training output tensors into the default S3 bucket. The format of the default S3 bucket URI is `s3://sagemaker-<region>-<12digit_account_id>/<training-job-name>/debug-output/`.

If you want to specify an exact S3 bucket URI, use the following code example:

```
from sagemaker.debugger import DebuggerHookConfig  
  
debugger_hook_config=DebuggerHookConfig(  
    s3_output_path="specify-your-s3-bucket-uri"  
    collection_configs=collection_configs  
)
```

For more information, see [DebuggerHookConfig](#) in the [Amazon SageMaker Python SDK](#).

## Example Notebooks and Code Samples to Configure Debugger Hook

The following sections provide notebooks and code examples of how to use Debugger hook to save, access, and visualize output tensors.

### Topics

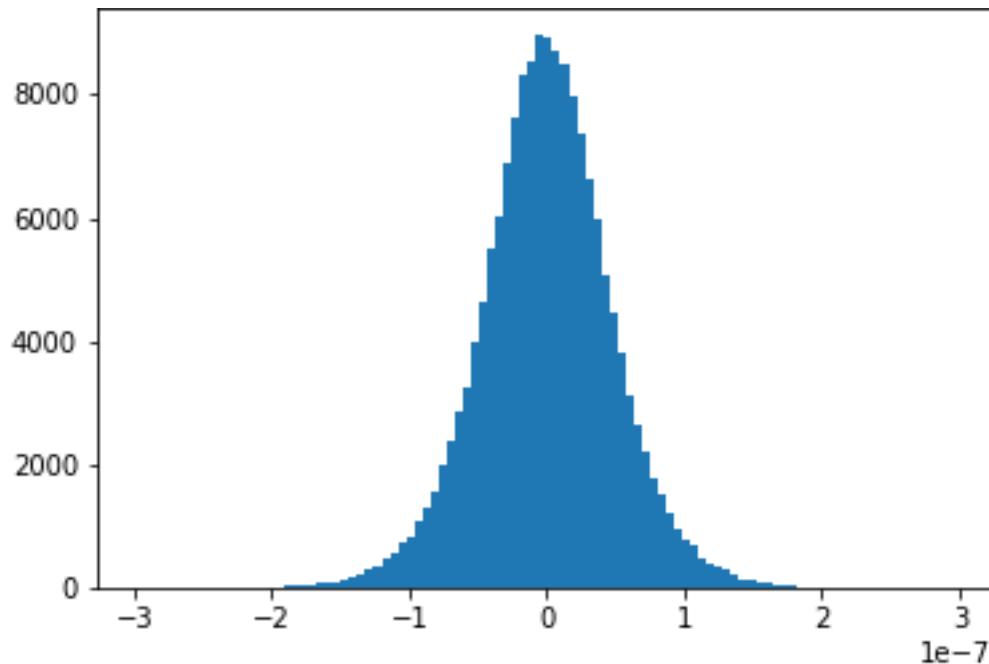

- [Tensor Visualization Example Notebooks \(p. 1604\)](#)
- [Save Tensors Using Debugger Built-in Collections \(p. 1606\)](#)
- [Save Tensors Using Debugger Modified Built-in Collections \(p. 1607\)](#)
- [Save Tensors Using Debugger Custom Collections \(p. 1607\)](#)

### Tensor Visualization Example Notebooks

The following two notebook examples show advanced use of Amazon SageMaker Debugger for visualizing tensors. Debugger provides a transparent view into training deep learning models.

- [Interactive Tensor Analysis in SageMaker Studio Notebook with MXNet](#)

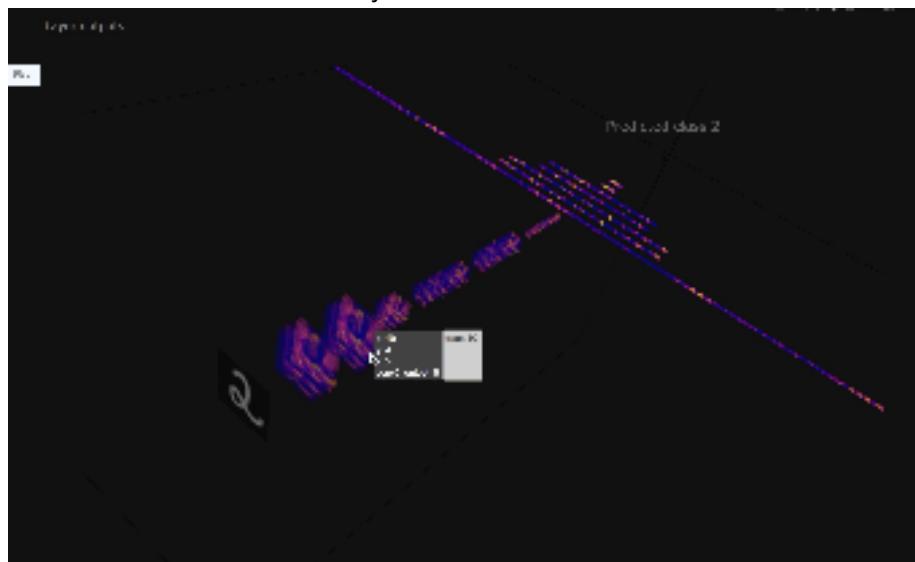

This notebook example shows how to visualize saved tensors using Amazon SageMaker Debugger. By visualizing the tensors, you can see how the tensor values change while training deep learning algorithms. This notebook includes a training job with a poorly configured neural network and uses Amazon SageMaker Debugger to aggregate and analyze tensors, including gradients, activation outputs, and weights. For example, the following plot shows the distribution of gradients of a convolutional layer that is suffering from a vanishing gradient problem.

This notebook also illustrates how a good initial hyperparameter setting improves the training process by generating the same tensor distribution plots.

- [Visualizing and Debugging Tensors from MXNet Model Training](#)

This notebook example shows how to save and visualize tensors from an MXNet Gluon model training job using Amazon SageMaker Debugger. It illustrates that Debugger is set to save all tensors to an Amazon S3 bucket and retrieves ReLU activation outputs for the visualization. The following figure shows a three-dimensional visualization of the ReLU activation outputs. The color scheme is set to blue to indicate values close to 0 and yellow to indicate values close to 1.

In this notebook, the `TensorPlot` class imported from `tensor_plot.py` is designed to plot convolutional neural networks (CNNs) that take two-dimensional images for inputs. The `tensor_plot.py` script provided with the notebook retrieves tensors using Debugger and visualizes

the CNN. You can run this notebook on SageMaker Studio to reproduce the tensor visualization and implement your own convolutional neural network model.

- [Real-time Tensor Analysis in a SageMaker Notebook with MXNet](#)

This example guides you through installing required components for emitting tensors in an Amazon SageMaker training job and using the Debugger API operations to access those tensors while training is running. A gluon CNN model is trained on the Fashion MNIST dataset. While the job is running, you will see how Debugger retrieves activation outputs of the first convolutional layer from each of 100 batches and visualizes them. Also, this will show you how to visualize weights after the job is done.

## Save Tensors Using Debugger Built-in Collections

You can use built-in collections of tensors using the `CollectionConfig` API and save them using the `DebuggerHookConfig` API. The following example shows how to use the default settings of Debugger hook configurations to construct a SageMaker TensorFlow estimator. You can also utilize this for MXNet, PyTorch, and XGBoost estimators.

### Note

In the following example code, the `s3_output_path` parameter for `DebuggerHookConfig` is optional. If you do not specify it, Debugger saves the tensors at `s3://<output_path>/debug-output/`, where the `<output_path>` is the default output path of SageMaker training jobs. For example:

```
"s3://sagemaker-us-east-1-111122223333/sagemaker-debugger-training-YYYY-MM-DD-HH-MM-SS-123/debug-output"
```

```
import sagemaker
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import DebuggerHookConfig, CollectionConfig

# use Debugger CollectionConfig to call built-in collections
collection_configs=[
    CollectionConfig(name="weights"),
    CollectionConfig(name="gradients"),
    CollectionConfig(name="losses"),
    CollectionConfig(name="biases")
]

# configure Debugger hook
# set a target S3 bucket as you want
sagemaker_session=sagemaker.Session()
BUCKET_NAME=sagemaker_session.default_bucket()
LOCATION_IN_BUCKET='debugger-built-in-collections-hook'

hook_config=DebuggerHookConfig(
    s3_output_path='s3://{BUCKET_NAME}/{LOCATION_IN_BUCKET}'.
        format(BUCKET_NAME=BUCKET_NAME,
               LOCATION_IN_BUCKET=LOCATION_IN_BUCKET),
    collection_configs=collection_configs
)

# construct a SageMaker TensorFlow estimator
sagemaker_estimator=TensorFlow(
    entry_point='directory/to/your_training_script.py',
    role=sm.get_execution_role(),
    base_job_name='debugger-demo-job',
    instance_count=1,
    instance_type="ml.m4.xlarge",
    framework_version="2.3.0",
    py_version="py37",
```

```

        # debugger-specific hook argument below
        debugger_hook_config=hook_config
    )

sagemaker_estimator.fit()

```

To see a list of Debugger built-in collections, see [Debugger Built-in Collections](#).

### Save Tensors Using Debugger Modified Built-in Collections

You can modify the Debugger built-in collections using the `CollectionConfig` API operation. The following example shows how to tweak the built-in `losses` collection and construct a SageMaker TensorFlow estimator. You can also use this for MXNet, PyTorch, and XGBoost estimators.

```

import sagemaker
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import DebuggerHookConfig, CollectionConfig

# use Debugger CollectionConfig to call and modify built-in collections
collection_configs=[
    CollectionConfig(
        name="losses",
        parameters={"save_interval": "50"})
]

# configure Debugger hook
# set a target S3 bucket as you want
sagemaker_session=sagemaker.Session()
BUCKET_NAME=sagemaker_session.default_bucket()
LOCATION_IN_BUCKET='debugger-modified-collections-hook'

hook_config=DebuggerHookConfig(
    s3_output_path='s3://{BUCKET_NAME}/{LOCATION_IN_BUCKET}'.format(BUCKET_NAME=BUCKET_NAME,
                                                                     LOCATION_IN_BUCKET=LOCATION_IN_BUCKET),
    collection_configs=collection_configs
)

# construct a SageMaker TensorFlow estimator
sagemaker_estimator=TensorFlow(
    entry_point='directory/to/your_training_script.py',
    role=sm.get_execution_role(),
    base_job_name='debugger-demo-job',
    instance_count=1,
    instance_type="ml.m4.xlarge",
    framework_version="2.3.0",
    py_version="py37",

    # debugger-specific hook argument below
    debugger_hook_config=hook_config
)

sagemaker_estimator.fit()

```

For a full list of `CollectionConfig` parameters, see [Debugger CollectionConfig API](#).

### Save Tensors Using Debugger Custom Collections

You can also save a reduced number of tensors instead of the full set of tensors (for example, if you want to reduce the amount of data saved in your Amazon S3 bucket). The following example shows how to customize the Debugger hook configuration to specify target tensors that you want to save. You can use this for TensorFlow, MXNet, PyTorch, and XGBoost estimators.

```

import sagemaker
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import DebuggerHookConfig, CollectionConfig

# use Debugger CollectionConfig to create a custom collection
collection_configs=[
    CollectionConfig(
        name="custom_activations_collection",
        parameters={
            "include_regex": "relu|tanh", # Required
            "reductions": "mean,variance,max,abs_mean,abs_variance,abs_max"
        })
]

# configure Debugger hook
# set a target S3 bucket as you want
sagemaker_session=sagemaker.Session()
BUCKET_NAME=sagemaker_session.default_bucket()
LOCATION_IN_BUCKET='debugger-custom-collections-hook'

hook_config=DebuggerHookConfig(
    s3_output_path='s3://{}{}/{}'.format(BUCKET_NAME, LOCATION_IN_BUCKET),
    collection_configs=collection_configs
)

# construct a SageMaker TensorFlow estimator
sagemaker_estimator=TensorFlow(
    entry_point='directory/to/your_training_script.py',
    role=sm.get_execution_role(),
    base_job_name='debugger-demo-job',
    instance_count=1,
    instance_type="ml.m4.xlarge",
    framework_version="2.3.0",
    py_version="py37",

    # debugger-specific hook argument below
    debugger_hook_config=hook_config
)

sagemaker_estimator.fit()

```

For a full list of `CollectionConfig` parameters, see [Debugger CollectionConfig](#).

## Configure Debugger Built-in Rules

Amazon SageMaker Debugger rules analyze tensors emitted during the training of a model. Debugger offers the `Rule API` operation that monitors training job progress and errors for the success of training your model. For example, the rules can detect whether gradients are getting too large or too small, whether a model is overfitting or overtraining, and whether a training job does not decrease loss function and improve. To see a full list of available built-in rules, see [List of Debugger Built-in Rules \(p. 1626\)](#).

### Note

The built-in rules are prepared in Amazon SageMaker processing containers and fully managed by SageMaker Debugger. By default, Debugger initiates the [ProfilerReport \(p. 1628\)](#) rule for all SageMaker training jobs, without any Debugger-specific rule parameter specified to the SageMaker estimators. The `ProfilerReport` rule invokes all of the following built-in rules for monitoring system bottlenecks and profiling framework metrics:

- [BatchSize \(p. 1629\)](#)

- [CPUBottleneck \(p. 1631\)](#)
- [GPUMemoryIncrease \(p. 1632\)](#)
- [IOBottleneck \(p. 1633\)](#)
- [LoadBalancing \(p. 1634\)](#)
- [LowGPUUtilization \(p. 1635\)](#)
- [OverallSystemUsage \(p. 1636\)](#)
- [MaxInitializationTime \(p. 1636\)](#)
- [OverallFrameworkMetrics \(p. 1637\)](#)
- [StepOutlier \(p. 1637\)](#)

Debugger saves the profiling report in a default S3 bucket. The format of the default S3 bucket URI is `s3://sagemaker-<region>-<12digit_account_id>/<training-job-name>/rule-output/`. For more information about how to download the profiling report, see [SageMaker Debugger Profiling Report \(p. 1701\)](#). SageMaker Debugger fully manages the built-in rules and analyzes your training job in parallel. For more information about billing, see the **Amazon SageMaker Studio is available at no additional charge** section of the [Amazon SageMaker Pricing](#) page.

In the following topics, learn how to use the Debugger built-in rules.

### Topics

- [Use Debugger Built-in Rules with the Default Parameter Settings \(p. 1609\)](#)
- [Use Debugger Built-in Rules with Custom Parameter Values \(p. 1610\)](#)
- [Example Notebooks and Code Samples to Configure Debugger Rules \(p. 1611\)](#)

## Use Debugger Built-in Rules with the Default Parameter Settings

To specify Debugger built-in rules in an estimator, you need to configure a `rules` list object. The following example code shows the basic structure of listing the Debugger built-in rules:

```
from sagemaker.debugger import Rule, ProfilerRule, rule_configs

rules=[  
    ProfilerRule.sagemaker(rule_configs.BuiltInProfilerRuleName_1()),  
    ProfilerRule.sagemaker(rule_configs.BuiltInProfilerRuleName_2()),  
    ...  
    ProfilerRule.sagemaker(rule_configs.BuiltInProfilerRuleName_n()),  
    Rule.sagemaker(rule_configs.built_in_rule_name_1()),  
    Rule.sagemaker(rule_configs.built_in_rule_name_2()),  
    ...  
    Rule.sagemaker(rule_configs.built_in_rule_name_n())  
]
```

For more information about default parameter values and descriptions of the built-in rule, see [List of Debugger Built-in Rules \(p. 1626\)](#).

For example, to inspect the overall training performance and progress of your model, construct a SageMaker estimator with the following built-in rule configuration.

```
from sagemaker.debugger import Rule, rule_configs

rules=[
```

```

    ProfilerRule.sagemaker(rule_configs.ProfilerReport()),
    Rule.sagemaker(rule_configs.loss_not_decreasing()),
    Rule.sagemaker(rule_configs.overfit()),
    Rule.sagemaker(rule_configs.overtraining()),
    Rule.sagemaker(rule_configs.stalled_training_rule())
]

```

When you start the training job, Debugger collects system resource utilization data every 500 milliseconds and the loss and accuracy values every 500 steps by default. Debugger analyzes the resource utilization to identify if your model is having bottleneck problems. The `loss_not_decreasing`, `overfit`, `overtraining`, and `stalled_training_rule` monitors if your model is optimizing the loss function without those training issues. If the rules detect training anomalies, the rule evaluation status changes to `IssueFound`. You can set up automated actions, such as notifying training issues and stopping training jobs using Amazon CloudWatch Events and Amazon Lambda. For more information, see [Action on Amazon SageMaker Rules \(p. 1675\)](#).

## Use Debugger Built-in Rules with Custom Parameter Values

If you want to adjust the built-in rule parameter values and customize tensor collection regex, configure the `base_config` and `rule_parameters` parameters for the `ProfilerRule.sagemaker` and `Rule.sagemaker` classmethods. In case of the `Rule.sagemaker` class methods, you can also customize tensor collections through the `collections_to_save` parameter. The instruction of how to use the `CollectionConfig` class is provided at [Configure Debugger Tensor Collections Using the CollectionConfig API Operation \(p. 1602\)](#).

Use the following configuration template for built-in rules to customize parameter values. By changing the rule parameters as you want, you can adjust the sensitivity of the rules to be triggered.

- The `base_config` argument is where you call the built-in rule methods.
- The `rule_parameters` argument is to adjust the default key values of the built-in rules listed in [List of Debugger Built-in Rules \(p. 1626\)](#).
- The `collections_to_save` argument takes in a tensor configuration through the `CollectionConfig` API, which requires `name` and `parameters` arguments.
  - To find available tensor collections for `name`, see [Debugger Built-in Tensor Collections](#).
  - For a full list of adjustable `parameters`, see [Debugger CollectionConfig API](#).

For more information about the Debugger rule class, methods, and parameters, see [SageMaker Debugger Rule class](#) in the [Amazon SageMaker Python SDK](#).

```

from sagemaker.debugger import Rule, ProfilerRule, rule_configs, CollectionConfig

rules=[
    ProfilerRule.sagemaker(
        base_config=rule_configs.BuiltInProfilerRuleName(),
        rule_parameters={
            "key": "value"
        }
    )
    Rule.sagemaker(
        base_config=rule_configs.built_in_rule_name(),
        rule_parameters={
            "key": "value"
        }
    )
    collections_to_save=[
        CollectionConfig(
            name="tensor_collection_name",
            parameters={

```

```
        "key": "value"
    }
]
]
```

The parameter descriptions and value customization examples are provided for each rule at [List of Debugger Built-in Rules \(p. 1626\)](#).

## Example Notebooks and Code Samples to Configure Debugger Rules

In the following sections, notebooks and code samples of how to use Debugger rules to monitor SageMaker training jobs are provided.

### Topics

- [Debugger Built-in Rules Example Notebooks \(p. 1611\)](#)
- [Debugger Built-in Rules Example Code \(p. 1612\)](#)
- [Use Debugger Built-in Rules with Parameter Modifications \(p. 1613\)](#)

### Debugger Built-in Rules Example Notebooks

The following example notebooks show how to use Debugger built-in rules when running training jobs with Amazon SageMaker:

- [Using a SageMaker Debugger built-in rule with TensorFlow](#)
- [Using a SageMaker Debugger built-in rule with Managed Spot Training and MXNet](#)
- [Using a SageMaker Debugger built-in rule with XGBoost](#)
- [Using a SageMaker Debugger built-in rule with parameter modifications for a real-time training job analysis with XGBoost](#)

While running the example notebooks in SageMaker Studio, you can find the training job trial created on the **Studio Experiment List** tab. For example, as shown in the following screenshot, you can find and open a **Describe Trial Component** window of your current training job. On the Debugger tab, you can check if the Debugger rules, `vanishing_gradient()` and `loss_not_decreasing()`, are monitoring the training session in parallel. For a full instruction of how to find your training job trial components in the Studio UI, see [SageMaker Studio - View Experiments, Trials, and Trial Components](#).

There are two ways of using the Debugger built-in rules in the SageMaker environment: deploy the built-in rules as it is prepared or adjust their parameters as you want. The following topics show you how to use the built-in rules with example codes.

### Debugger Built-in Rules Example Code

The following code sample shows how to set the Debugger built-in rules using the `Rule.sagemaker` method. To specify built-in rules that you want to run, use the `rules_configs` API operation to call the built-in rules. To find a full list of Debugger built-in rules and default parameter values, see [List of Debugger Built-in Rules \(p. 1626\)](#).

```

import sagemaker
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import Rule, CollectionConfig, rule_configs

# call built-in rules that you want to use.
built_in_rules=[
    Rule.sagemaker(rule_configs.vanishing_gradient())
    Rule.sagemaker(rule_configs.loss_not_decreasing())
]

# construct a SageMaker estimator with the Debugger built-in rules
sagemaker_estimator=TensorFlow(
    entry_point='directory/to/your_training_script.py',
    role=sm.get_execution_role(),
    base_job_name='debugger-built-in-rules-demo',
    rules=built_in_rules
)

```

```

    instance_count=1,
    instance_type="ml.m4.xlarge",
    framework_version="2.1.0",
    py_version="py3",

    # debugger-specific arguments below
    rules=built_in_rules
)
sagemaker_estimator.fit()

```

**Note**

The Debugger built-in rules run in parallel with your training job. The maximum number of built-in rule containers for a training job is 20.

For more information about the Debugger rule class, methods, and parameters, see the [SageMaker Debugger Rule class](#) in the [Amazon SageMaker Python SDK](#).

To find an example of how to adjust the Debugger rule parameters, see the following [Use Debugger Built-in Rules with Parameter Modifications \(p. 1613\)](#) section.

### Use Debugger Built-in Rules with Parameter Modifications

The following code example shows the structure of built-in rules to adjust parameters. In this example, the `stalled_training_rule` collects the `losses` tensor collection from a training job at every 50 steps and an evaluation stage at every 10 steps. If the training process starts stalling and not collecting tensor outputs for 120 seconds, the `stalled_training_rule` stops the training job.

```

import sagemaker
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import Rule, CollectionConfig, rule_configs

# call the built-in rules and modify the CollectionConfig parameters

base_job_name_prefix= 'smdebug-stalled-demo-' + str(int(time.time()))

built_in_rules_modified=[

    Rule.sagemaker(
        base_config=rule_configs.stalled_training_rule(),
        rule_parameters={
            'threshold': '120',
            'training_job_name_prefix': base_job_name_prefix,
            'stop_training_on_fire' : 'True'
        }
    ),
    collections_to_save=[
        CollectionConfig(
            name="losses",
            parameters={
                "train.save_interval": "50"
                "eval.save_interval": "10"
            }
        )
    ]
]

# construct a SageMaker estimator with the modified Debugger built-in rule
sagemaker_estimator=TensorFlow(
    entry_point='directory/to/your_training_script.py',
    role=sm.get_execution_role(),
    base_job_name=base_job_name_prefix,
    instance_count=1,
    instance_type="ml.m4.xlarge",
    framework_version="2.1.0",
    py_version="py3",
)

```

```
# debugger-specific arguments below
rules=built_in_rules_modified
)
sagemaker_estimator.fit()
```

For an advanced configuration of the Debugger built-in rules using the [CreateTrainingJob API](#), see [Configure Debugger Using Amazon SageMaker API \(p. 1615\)](#).

## Turn Off Debugger

If you want to completely turn off Debugger, do one of the following:

- Before starting a training job, do the following:

To disable both monitoring and profiling, include the `disable_profiler` parameter to your estimator and set it to `True`.

**Warning**

If you disable it, you won't be able to view the comprehensive Studio Debugger insights dashboard and the autogenerated profiling report.

To disable debugging, set the `debugger_hook_config` parameter to `False`.

**Warning**

If you disable it, you won't be able to collect output tensors and cannot debug your model parameters.

```
estimator=Estimator(
    ...
    disable_profiler=True
    debugger_hook_config=False
)
```

For more information about the Debugger-specific parameters, see [SageMaker Estimator](#) in the [Amazon SageMaker Python SDK](#).

- While a training job is running, do the following:

To disable both monitoring and profiling while your training job is running, use the following estimator classmethod:

```
estimator.disable_profiling()
```

To disable framework profiling only and keep system monitoring, use the `update_profiler` method:

```
estimator.update_profiler(disable_framework_metrics=true)
```

For more information about the estimator extension methods, see the `estimator.disable_profiling` and `estimator.update_profiler` classmethods in the [Amazon SageMaker Python SDK](#) documentation.

## Useful SageMaker Estimator Classmethods for Debugger

The following estimator class methods are useful for accessing your SageMaker training job information and retrieving output paths of training data collected by Debugger. The following methods are executable after you initiate a training job with the `estimator.fit()` method.

- To check the base S3 bucket URI of a SageMaker training job:

```
estimator.output_path
```

- To check the base job name of a SageMaker training job:

```
estimator.latest_training_job.job_name
```

- To see a full CreateTrainingJob API operation configuration of a SageMaker training job:

```
estimator.latest_training_job.describe()
```

- To check a full list of the Debugger rules while a SageMaker training job is running:

```
estimator.latest_training_job.rule_job_summary()
```

- To check the S3 bucket URI where the model parameter data (output tensors) are saved:

```
estimator.latest_job_debugger_artifacts_path()
```

- To check the S3 bucket URI at where the model performance data (system and framework metrics) are saved:

```
estimator.latest_job_profiler_artifacts_path()
```

- To check the Debugger rule configuration for debugging output tensors:

```
estimator.debugger_rule_configs
```

- To check the list of the Debugger rules for debugging while a SageMaker training job is running:

```
estimator.debugger_rules
```

- To check the Debugger rule configuration for monitoring and profiling system and framework metrics:

```
estimator.profiler_rule_configs
```

- To check the list of the Debugger rules for monitoring and profiling while a SageMaker training job is running:

```
estimator.profiler_rules
```

For more information about the SageMaker estimator class and its methods, see [Estimator API](#) in the [Amazon SageMaker Python SDK](#).

## Configure Debugger Using Amazon SageMaker API

The preceding topics focus on using Debugger through Amazon SageMaker Python SDK, which is a wrapper around Amazon SDK for Python (Boto3) and SageMaker API operations. This offers a high-level experience of accessing the Amazon SageMaker API operations. In case you need to manually configure the SageMaker API operations using Amazon Boto3 or Amazon Command Line Interface (CLI) for other SDKs, such as Java, Go, and C++, this guide covers how to configure [CreateTrainingJob](#), [UpdateTrainingJob](#), Debugger configuration APIs, and their parameters to use the Debugger built-in and custom rules.

## Topics

- [JSON \(Amazon CLI\) \(p. 1616\)](#)
- [Amazon Boto3 \(p. 1620\)](#)

## JSON (Amazon CLI)

Amazon SageMaker Debugger built-in rules can be configured for a training job using the [DebugHookConfig](#), [DebugRuleConfiguration](#), [ProfilerConfig](#), and [ProfilerRuleConfiguration](#) objects through the SageMaker [CreateTrainingJob](#) API operation. You need to specify the right image URI in the `RuleEvaluatorImage` parameter, and the following examples walk you through how to set up the JSON strings to request [CreateTrainingJob](#).

The following code shows a complete JSON template to run a training job with required settings and Debugger configurations. Save the template as a JSON file in your working directory and run the training job using Amazon CLI. For example, save the following code as `debugger-training-job-cli.json`.

### Note

Ensure that you use the correct Docker container images. To find Amazon Deep Learning Container images, see [Available Deep Learning Containers Images](#). To find a complete list of available Docker images for using the Debugger rules, see [Use Debugger Docker Images for Built-in or Custom Rules \(p. 1738\)](#).

        }
    }
}

```

After saving the JSON file, run the following command in your terminal. (Use ! at the beginning of the line if you use a Jupyter notebook.)

```
aws sagemaker create-training-job --cli-input-json file://debugger-training-job-cli.json
```

## To configure a Debugger rule for debugging model parameters

The following code samples show how to configure a built-in VanishingGradient rule using this SageMaker API.

### To enable Debugger to collect output tensors

Specify the Debugger hook configuration as follows:

```

"DebugHookConfig": {
    "S3OutputPath": "s3://<default-bucket>/<training-job-name>/debug-output",
    "CollectionConfigurations": [
        {
            "CollectionName": "gradients",
            "CollectionParameters" : {
                "save_interval": "500"
            }
        }
    ]
}

```

This will make the training job save the tensor collection, gradients, every save\_interval of 500 steps. To find available CollectionName values, see [Debugger Built-in Collections](#) in the *SMDebug*

*client library documentation.* To find available CollectionParameters parameter keys and values, see the `sagemaker.debugger.CollectionConfig` class in the *SageMaker Python SDK documentation*.

### To enable Debugger rules for debugging the output tensors

The following DebugRuleConfigurations API example shows how to run the built-in VanishingGradient rule on the saved gradients collection.

```
"DebugRuleConfigurations": [
    {
        "RuleConfigurationName": "VanishingGradient",
        "RuleEvaluatorImage": "503895931360.dkr.ecr.us-east-1.amazonaws.com/sagemaker-
debugger-rules:latest",
        "RuleParameters": {
            "rule_to_invoke": "VanishingGradient",
            "threshold": "20.0"
        }
    }
]
```

With a configuration like the one in this sample, Debugger starts a rule evaluation job for your training job using the VanishingGradient rule on the collection of gradients tensor. To find a complete list of available Docker images for using the Debugger rules, see [Use Debugger Docker Images for Built-in or Custom Rules \(p. 1738\)](#). To find the key-value pairs for RuleParameters, see [List of Debugger Built-in Rules \(p. 1626\)](#).

### To configure a Debugger built-in rule for profiling system and framework metrics

The following example code shows how to specify the ProfilerConfig API operation to enable collecting system and framework metrics.

#### To enable Debugger profiling to collect system and framework metrics

##### Target Step

```
"ProfilerConfig": {
    // Optional. Path to an S3 bucket to save profiling outputs
    "S3OutputPath": "s3://<default-bucket>/<training-job-name>/profiler-output",
    // Available values for ProfilingIntervalInMilliseconds: 100, 200, 500, 1000 (1
second), 5000 (5 seconds), and 60000 (1 minute) milliseconds.
    "ProfilingIntervalInMilliseconds": 500,
    "ProfilingParameters": {
        "DataloaderProfilingConfig": "{ \"StartStep\": 5, \"NumSteps\": 3,
\"MetricsRegex\": \".*\\\" }",
        "DetailedProfilingConfig": "{ \"StartStep\": 5, \"NumSteps\": 3 }",
        // For PythonProfilingConfig,
        // available ProfilerName options: cProfile, Pyinstrument
        // available cProfileTimer options only when using cProfile: cpu, off_cpu,
        total_time
        "PythonProfilingConfig": "{ \"StartStep\": 5, \"NumSteps\": 3, \"ProfilerName\":
\"cProfile\", \"cProfileTimer\": \"total_time\" }",
        // Optional. Local path for profiling outputs
        "LocalPath": "/opt/ml/output/profiler/"
    }
}
```

##### Target Time Duration

```
"ProfilerConfig": {
    // Optional. Path to an S3 bucket to save profiling outputs
```

```

    "S3OutputPath": "s3://<default-bucket>/<training-job-name>/profiler-output",
    // Available values for ProfilingIntervalInMilliseconds: 100, 200, 500, 1000 (1
second), 5000 (5 seconds), and 60000 (1 minute) milliseconds.
    "ProfilingIntervalInMilliseconds": 500,
    "ProfilingParameters": {
        "DataLoaderProfilingConfig": "{ \"StartTimeInSecSinceEpoch\": 12345567789,
\"DurationInSeconds\": 10, \"MetricsRegex\": \".*\" }",
        "DetailedProfilingConfig": "{ \"StartTimeInSecSinceEpoch\": 12345567789,
\"DurationInSeconds\": 10 }",
        // For PythonProfilingConfig,
        // available ProfilerName options: cProfile, Pyinstrument
        // available cProfileTimer options only when using cProfile: cpu, off_cpu,
total_time
        "PythonProfilingConfig": "{ \"StartTimeInSecSinceEpoch\": 12345567789,
\"DurationInSeconds\": 10, \"ProfilerName\": \"cProfile\", \"cProfileTimer\":
\"total_time\" }",
        // Optional. Local path for profiling outputs
        "LocalPath": "/opt/ml/output/profiler/"
    }
}

```

### To enable Debugger rules for profiling the metrics

The following example code shows how to configure the `ProfilerReport` rule.

```

"ProfilerRuleConfigurations": [
{
    "RuleConfigurationName": "ProfilerReport",
    "RuleEvaluatorImage": "895741380848.dkr.ecr.us-west-2.amazonaws.com/sagemaker-
debugger-rules:latest",
    "RuleParameters": {
        "rule_to_invoke": "ProfilerReport",
        "CPUBottleneck_cpu_threshold": "90",
        "IOBottleneck_threshold": "90"
    }
}
]

```

To find a complete list of available Docker images for using the Debugger rules, see [Use Debugger Docker Images for Built-in or Custom Rules \(p. 1738\)](#). To find the key-value pairs for `RuleParameters`, see [List of Debugger Built-in Rules \(p. 1626\)](#).

## Update Debugger Profiling Configuration Using the `UpdateTrainingJob` API Operation

Debugger profiling configuration can be updated while your training job is running by using the `UpdateTrainingJob` API operation. Configure new `ProfilerConfig` and `ProfilerRuleConfiguration` objects, and specify the training job name to the `TrainingJobName` parameter.

```

{
    "ProfilerConfig": {
        "DisableProfiler": boolean,
        "ProfilingIntervalInMilliseconds": number,
        "ProfilingParameters": {
            "string" : "string"
        }
    },
    "ProfilerRuleConfigurations": [
        {
            "RuleConfigurationName": "string",
            "RuleEvaluatorImage": "string",
            ...
        }
    ]
}

```

```

        "RuleParameters": {
            "string" : "string"
        }
    },
    "TrainingJobName": "your-training-job-name-YYYY-MM-DD-HH-MM-SS-SSS"
}

```

## Add Debugger Custom Rule Configuration to the CreateTrainingJob API Operation

A custom rule can be configured for a training job using the [DebugHookConfig](#) and [DebugRuleConfiguration](#) objects in the [CreateTrainingJob](#) API operation. The following code sample shows how to configure a custom `ImproperActivation` rule written with the `smdebug` library using this SageMaker API operation. This example assumes that you've written the custom rule in `custom_rules.py` file and uploaded it to an Amazon S3 bucket. The example provides pre-built Docker images that you can use to run your custom rules. These are listed at [Amazon SageMaker Debugger Registry URLs for Custom Rule Evaluators \(p. 1739\)](#). You specify the URL registry address for the pre-built Docker image in the `RuleEvaluatorImage` parameter.

```

"DebugHookConfig": {
    "S3OutputPath": "s3://<default-bucket>/<training-job-name>/debug-output",
    "CollectionConfigurations": [
        {
            "CollectionName": "relu_activations",
            "CollectionParameters": {
                "include_regex": "relu",
                "save_interval": "500",
                "end_step": "5000"
            }
        }
    ],
    "DebugRulesConfigurations": [
        {
            "RuleConfigurationName": "improper_activation_job",
            "RuleEvaluatorImage": "552407032007.dkr.ecr.ap-south-1.amazonaws.com/sagemaker-
debugger-rule-evaluator:latest",
            "InstanceType": "ml.c4.xlarge",
            "VolumeSizeInGB": 400,
            "RuleParameters": {
                "source_s3_uxi": "s3://bucket/custom_rules.py",
                "rule_to_invoke": "ImproperActivation",
                "collection_names": "relu_activations"
            }
        }
    ]
}

```

To find a complete list of available Docker images for using the Debugger rules, see [Use Debugger Docker Images for Built-in or Custom Rules \(p. 1738\)](#). To find the key-value pairs for `RuleParameters`, see [List of Debugger Built-in Rules \(p. 1626\)](#).

## Amazon Boto3

Amazon SageMaker Debugger built-in rules can be configured for a training job using the `create_training_job()` function of the Amazon Boto3 SageMaker client. You need to specify the right image URI in the `RuleEvaluatorImage` parameter, and the following examples walk you through how to set up the request body for the `create_training_job()` function.

The following code shows a complete example of how to configure Debugger for the `create_training_job()` request body and start a training job in `us-west-2`, assuming that a

training script `entry_point/train.py` is prepared using TensorFlow. To find an end-to-end example notebook, see [Profiling TensorFlow Multi GPU Multi Node Training Job with Amazon SageMaker Debugger \(Boto3\)](#).

**Note**

Ensure that you use the correct Docker container images. To find available Amazon Deep Learning Container images, see [Available Deep Learning Containers Images](#). To find a complete list of available Docker images for using the Debugger rules, see [Use Debugger Docker Images for Built-in or Custom Rules \(p. 1738\)](#).

```
import sagemaker, boto3
import datetime, tarfile

# Start setting up a SageMaker session and a Boto3 SageMaker client
session = sagemaker.Session()
region = session.boto_region_name
bucket = session.default_bucket()

# Upload a training script to a default Amazon S3 bucket of the current SageMaker session
source = 'source.tar.gz'
project = 'debugger-boto3-test'

tar = tarfile.open(source, 'w:gz')
tar.add ('entry_point/train.py') # Specify the directory and name of your training script
tar.close()

s3 = boto3.client('s3')
s3.upload_file(source, bucket, project+'/'+source)

# Set up a Boto3 session client for SageMaker
sm = boto3.Session(region_name=region).client("sagemaker")

# Start a training job
sm.create_training_job(
    TrainingJobName='debugger-boto3-'+datetime.datetime.now().strftime('%Y-%m-%d-%H-%M-%S'),
    HyperParameters={
        'sagemaker_submit_directory': 's3://'+bucket+'/'+project+'/'+source,
        'sagemaker_program': '/entry_point/train.py' # training scrip file location and name under the sagemaker_submit_directory
    },
    AlgorithmSpecification={
        # Specify a training Docker container image URI (Deep Learning Container or your own training container) to TrainingImage.
        'TrainingImage': '763104351884.dkr.ecr.us-west-2.amazonaws.com/tensorflow-training:2.4.1-gpu-py37-cu110-ubuntu18.04',
        'TrainingInputMode': 'File',
        'EnableSageMakerMetricsTimeSeries': False
    },
    RoleArn='arn:aws:iam::111122223333:role/service-role/AmazonSageMaker-ExecutionRole-20201014T161125',
    OutputDataConfig={'S3OutputPath': 's3://'+bucket+'/'+project+'/output'},
    ResourceConfig={
        'InstanceType': 'ml.p3.8xlarge',
        'InstanceCount': 1,
        'VolumeSizeInGB': 30
    },
    StoppingCondition={
        'MaxRuntimeInSeconds': 86400
    },
    DebugHookConfig={
        'S3OutputPath': 's3://'+bucket+'/'+project+'/debug-output',
        'CollectionConfigurations': [
            {
                'CollectionName': 'losses',
            }
        ]
    }
)
```

```

        'CollectionParameters' : {
            'train.save_interval': '500',
            'eval.save_interval': '50'
        }
    }
},
DebugRuleConfigurations=[
{
    'RuleConfigurationName': 'LossNotDecreasing',
    'RuleEvaluatorImage': '895741380848.dkr.ecr.us-west-2.amazonaws.com/sagemaker-
debugger-rules:latest',
    'RuleParameters': {'rule_to_invoke': 'LossNotDecreasing'}
},
],
ProfilerConfig={
    'S3OutputPath': 's3://'+bucket+'/'+project+'/profiler-output',
    'ProfilingIntervalInMilliseconds': 500,
    'ProfilingParameters': {
        'DataloaderProfilingConfig': '{"StartStep": 5, "NumSteps": 3, "MetricsRegex": 
".*", }',
        'DetailedProfilingConfig': '{"StartStep": 5, "NumSteps": 3, }',
        'PythonProfilingConfig': '{"StartStep": 5, "NumSteps": 3, "ProfilerName": 
"cprofile", "cProfileTimer": "total_time"}',
        'LocalPath': '/opt/ml/output/profiler/' # Optional. Local path for profiling
outputs
    }
},
ProfilerRuleConfigurations=[
{
    'RuleConfigurationName': 'ProfilerReport',
    'RuleEvaluatorImage': '895741380848.dkr.ecr.us-west-2.amazonaws.com/sagemaker-
debugger-rules:latest',
    'RuleParameters': {'rule_to_invoke': 'ProfilerReport'}
}
]
)

```

To configure a Debugger rule for debugging model parameters

The following code samples show how to configure a built-in `VanishingGradient` rule using this SageMaker API.

## To enable Debugger to collect output tensors

Specify the Debugger hook configuration as follows:

```
DebugHookConfig={  
    'S3OutputPath': 's3://<default-bucket>/<training-job-name>/debug-output',  
    'CollectionConfigurations': [  
        {  
            'CollectionName': 'gradients',  
            'CollectionParameters' : {  
                'train.save_interval': '500',  
                'eval.save_interval': '50'  
            }  
        }  
    ]  
}
```

This will make the training job save a tensor collection, gradients, every `save_interval` of 500 steps. To find available `CollectionName` values, see [Debugger Built-in Collections](#) in the *SMDebug client*.

*library documentation.* To find available CollectionParameters parameter keys and values, see the [sagemaker.debugger.CollectionConfig](#) class in the *SageMaker Python SDK documentation*.

### To enable Debugger rules for debugging the output tensors

The following DebugRuleConfigurations API example shows how to run the built-in VanishingGradient rule on the saved gradients collection.

```
DebugRuleConfigurations=[
    {
        'RuleConfigurationName': 'VanishingGradient',
        'RuleEvaluatorImage': '895741380848.dkr.ecr.us-west-2.amazonaws.com/sagemaker-
debugger-rules:latest',
        'RuleParameters': {
            'rule_to_invoke': 'VanishingGradient',
            'threshold': '20.0'
        }
    }
]
```

With a configuration like the one in this sample, Debugger starts a rule evaluation job for your training job using the VanishingGradient rule on the collection of gradients tensor. To find a complete list of available Docker images for using the Debugger rules, see [Use Debugger Docker Images for Built-in or Custom Rules \(p. 1738\)](#). To find the key-value pairs for RuleParameters, see [List of Debugger Built-in Rules \(p. 1626\)](#).

### To configure a Debugger built-in rule for profiling system and framework metrics

The following example code shows how to specify the ProfilerConfig API operation to enable collecting system and framework metrics.

#### To enable Debugger profiling to collect system and framework metrics

##### Target Step

```
ProfilerConfig={
    'S3OutputPath': 's3://<default-bucket>/<training-job-name>/profiler-output', #
    Optional. Path to an S3 bucket to save profiling outputs
    # Available values for ProfilingIntervalInMilliseconds: 100, 200, 500, 1000 (1
    second), 5000 (5 seconds), and 60000 (1 minute) milliseconds.
    'ProfilingIntervalInMilliseconds': 500,
    'ProfilingParameters': {
        'DataloaderProfilingConfig': '{
            "StartStep": 5,
            "NumSteps": 3,
            "MetricsRegex": ".*"
        }',
        'DetailedProfilingConfig': '{
            "StartStep": 5,
            "NumSteps": 3
        }',
        'PythonProfilingConfig': '{
            "StartStep": 5,
            "NumSteps": 3,
            "ProfilerName": "cprofile", # Available options: cprofile, pyinstrument
            "cProfileTimer": "total_time" # Include only when using cprofile.
        }',
        'LocalPath': '/opt/ml/output/profiler/' # Optional. Local path for profiling
    outputs
    }
```

```
}
```

## Target Time Duration

```

ProfilerConfig={
    'S3OutputPath': 's3://<default-bucket>/<training-job-name>/profiler-output', #
    Optional. Path to an S3 bucket to save profiling outputs
    # Available values for ProfilingIntervalInMilliseconds: 100, 200, 500, 1000 (1
    # second), 5000 (5 seconds), and 60000 (1 minute) milliseconds.
    'ProfilingIntervalInMilliseconds': 500,
    'ProfilingParameters': {
        'DataloaderProfilingConfig': '{'
            "StartTimeInSecSinceEpoch": 12345567789,
            "DurationInSeconds": 10,
            "MetricsRegex": ".*"
        },
        'DetailedProfilingConfig': '{'
            "StartTimeInSecSinceEpoch": 12345567789,
            "DurationInSeconds": 10
        },
        'PythonProfilingConfig': '{'
            "StartTimeInSecSinceEpoch": 12345567789,
            "DurationInSeconds": 10,
            "ProfilerName": "cprofile", # Available options: cprofile, pyinstrument
            "cProfileTimer": "total_time" # Include only when using cprofile.
        Available options: cpu, off_cpu, total_time
        },
        'LocalPath': '/opt/ml/output/profiler/' # Optional. Local path for profiling
    outputs
    }
}

```

## To enable Debugger rules for profiling the metrics

The following example code shows how to configure the `ProfilerReport` rule.

```

ProfilerRuleConfigurations=[
    {
        'RuleConfigurationName': 'ProfilerReport',
        'RuleEvaluatorImage': '895741380848.dkr.ecr.us-west-2.amazonaws.com/sagemaker-
debugger-rules:latest',
        'RuleParameters': {
            'rule_to_invoke': 'ProfilerReport',
            'CPUBottleneck_cpu_threshold': '90',
            'IOBottleneck_threshold': '90'
        }
    }
]

```

To find a complete list of available Docker images for using the Debugger rules, see [Use Debugger Docker Images for Built-in or Custom Rules \(p. 1738\)](#). To find the key-value pairs for `RuleParameters`, see [List of Debugger Built-in Rules \(p. 1626\)](#).

## Update Debugger Profiling Configuration Using the `UpdateTrainingJob` API Operation

Debugger profiling configuration can be updated while your training job is running by using the `update_training_job()` function of the Amazon Boto3 SageMaker client. Configure new `ProfilerConfig` and `ProfilerRuleConfiguration` objects, and specify the training job name to the `TrainingJobName` parameter.

```

ProfilerConfig={
    'DisableProfiler': boolean,
    'ProfilingIntervalInMilliseconds': number,
    'ProfilingParameters': {
        'string' : 'string'
    }
},
ProfilerRuleConfigurations=[
{
    'RuleConfigurationName': 'string',
    'RuleEvaluatorImage': 'string',
    'RuleParameters': {
        'string' : 'string'
    }
}
],
TrainingJobName='your-training-job-name-YYYY-MM-DD-HH-MM-SS-SSS'

```

## Add Debugger Custom Rule Configuration to the CreateTrainingJob API Operation

A custom rule can be configured for a training job using the [DebugHookConfig](#) and [DebugRuleConfiguration](#) objects using the Amazon Boto3 SageMaker client's [create\\_training\\_job\(\)](#) function. The following code sample shows how to configure a custom `ImproperActivation` rule written with the `smdebug` library using this SageMaker API operation. This example assumes that you've written the custom rule in `custom_rules.py` file and uploaded it to an Amazon S3 bucket. The example provides pre-built Docker images that you can use to run your custom rules. These are listed at [Amazon SageMaker Debugger Registry URLs for Custom Rule Evaluators \(p. 1739\)](#). You specify the URL registry address for the pre-built Docker image in the `RuleEvaluatorImage` parameter.

```

DebugHookConfig={
    'S3OutputPath': 's3://<default-bucket>/<training-job-name>/debug-output',
    'CollectionConfigurations': [
        {
            'CollectionName': 'relu_activations',
            'CollectionParameters': {
                'include_regex': 'relu',
                'save_interval': '500',
                'end_step': '5000'
            }
        }
    ]
},
DebugRulesConfigurations=[
{
    'RuleConfigurationName': 'improper_activation_job',
    'RuleEvaluatorImage': '552407032007.dkr.ecr.ap-south-1.amazonaws.com/sagemaker-
debugger-rule-evaluator:latest',
    'InstanceType': 'ml.c4.xlarge',
    'VolumeSizeInGB': 400,
    'RuleParameters': {
        'source_s3_uri': 's3://bucket/custom_rules.py',
        'rule_to_invoke': 'ImproperActivation',
        'collection_names': 'relu_activations'
    }
}
]

```

To find a complete list of available Docker images for using the Debugger rules, see [Use Debugger Docker Images for Built-in or Custom Rules \(p. 1738\)](#). To find the key-value pairs for `RuleParameters`, see [List of Debugger Built-in Rules \(p. 1626\)](#).

## List of Debugger Built-in Rules

Use the Debugger built-in rules provided by Amazon SageMaker Debugger and analyze tensors emitted while training your models. The Debugger built-in rules monitor various common conditions that are critical for the success of a training job. You can call the built-in rules using [Amazon SageMaker Python SDK](#) or the low-level SageMaker API operations. Depending on deep learning frameworks of your choice, there are four scopes of validity for the built-in rules as shown in the following table.

### Note

The maximum numbers of built-in rules for a training job are 20 for `ProfilerRule` and 20 for `Rule`. SageMaker Debugger fully manages the built-in rules and analyzes your training job in parallel. For more information about billing, see the [Amazon SageMaker Studio is available at no additional charge](#) section of the [Amazon SageMaker Pricing](#) page.

### Important

To use the new Debugger features, you need to upgrade the SageMaker Python SDK and the SMDebug client library. In your iPython kernel, Jupyter notebook, or JupyterLab environment, run the following code to install the latest versions of the libraries and restart the kernel.

```
import sys
import IPython
!{sys.executable} -m pip install -U sagemaker smdebug
IPython.Application.instance().kernel.do_shutdown(True)
```

## Debugger ProfilerRule

The following rules are the Debugger built-in rules that are callable using the `ProfilerRule.sagemaker` classmethod.

### Debugger Built-in Rules for Generating Profiling Reports

Scope of Validity	Built-in Rules
Profiling Report for any SageMaker training job	<ul style="list-style-type: none"><li><a href="#">ProfilerReport (p. 1628)</a></li></ul>

### Debugger Built-in Rules for Monitoring Hardware System Resource Utilization (System Metrics)

Scope of Validity	Built-in Rules
Generic system monitoring rules for any SageMaker training job	<ul style="list-style-type: none"><li><a href="#">BatchSize (p. 1629)</a></li><li><a href="#">CPUBottleneck (p. 1631)</a></li><li><a href="#">GPUMemoryIncrease (p. 1632)</a></li><li><a href="#">IOBottleneck (p. 1633)</a></li><li><a href="#">LoadBalancing (p. 1634)</a></li><li><a href="#">LowGPUUtilization (p. 1635)</a></li><li><a href="#">OverallSystemUsage (p. 1636)</a></li></ul>

### Debugger Built-in Rules for Profiling Framework Metrics

Scope of Validity	Built-in Rules
Profiling rules for deep learning frameworks (TensorFlow and PyTorch)	<ul style="list-style-type: none"><li><a href="#">MaxInitializationTime (p. 1636)</a></li><li><a href="#">OverallFrameworkMetrics (p. 1637)</a></li></ul>

Scope of Validity	Built-in Rules
	<ul style="list-style-type: none"> <li>• <a href="#">StepOutlier (p. 1637)</a></li> </ul>

## Debugger Rule

The following rules are the Debugger built-in rules that are callable using the `Rule.sagemaker` classmethod.

### Debugger Built-in Rules for Generating Training Reports

Scope of Validity	Built-in Rules
Training Report for SageMaker XGboost training job	<ul style="list-style-type: none"> <li>• <a href="#">create_xgboost_report (p. 1638)</a></li> </ul>

### Debugger Built-in Rules for Debugging Model Training Data (Output Tensors)

Scope of Validity	Built-in Rules
Deep learning frameworks (TensorFlow, MXNet, and PyTorch)	<ul style="list-style-type: none"> <li>• <a href="#">dead_relu (p. 1639)</a></li> <li>• <a href="#">exploding_tensor (p. 1640)</a></li> <li>• <a href="#">poor_weight_initialization (p. 1641)</a></li> <li>• <a href="#">saturated_activation (p. 1643)</a></li> <li>• <a href="#">vanishing_gradient (p. 1646)</a></li> <li>• <a href="#">weight_update_ratio (p. 1647)</a></li> </ul>
Deep learning frameworks (TensorFlow, MXNet, and PyTorch) and the XGBoost algorithm	<ul style="list-style-type: none"> <li>• <a href="#">all_zero (p. 1648)</a></li> <li>• <a href="#">class_imbalance (p. 1650)</a></li> <li>• <a href="#">loss_not_decreasing (p. 1652)</a></li> <li>• <a href="#">overfit (p. 1654)</a></li> <li>• <a href="#">overtraining (p. 1655)</a></li> <li>• <a href="#">similar_across_runs (p. 1657)</a></li> <li>• <a href="#">stalled_training_rule (p. 1658)</a></li> <li>• <a href="#">tensor_variance (p. 1659)</a></li> <li>• <a href="#">unchanged_tensor (p. 1661)</a></li> </ul>
Deep learning applications	<ul style="list-style-type: none"> <li>• <a href="#">check_input_images (p. 1663)</a></li> <li>• <a href="#">nlp_sequence_ratio (p. 1664)</a></li> </ul>
XGBoost algorithm	<ul style="list-style-type: none"> <li>• <a href="#">confusion (p. 1666)</a></li> <li>• <a href="#">feature_importance_overweight (p. 1668)</a></li> <li>• <a href="#">tree_depth (p. 1669)</a></li> </ul>

**To use the built-in rules with default parameter values** – use the following configuration format:

```
from sagemaker.debugger import Rule, ProfilerRule, rule_configs

rules = [
    ProfilerRule.sagemaker(rule_configs.BuiltInRuleName_1()),
    ProfilerRule.sagemaker(rule_configs.BuiltInRuleName_2()),
    ...
]
```

```
    ProfilerRule.sagemaker(rule_configs.BuiltInRuleName_n())),
    Rule.sagemaker(rule_configs.built_in_rule_name_1()),
    Rule.sagemaker(rule_configs.built_in_rule_name_2()),
    ...
    Rule.sagemaker(rule_configs.built_in_rule_name_n()))
]
```

**To use the built-in rules with customizing the parameter values** – use the following configuration format:

```
from sagemaker.debugger import Rule, ProfilerRule, rule_configs

rules = [
    ProfilerRule.sagemaker(
        base_config=rule_configs.BuiltInRuleName(),
        rule_parameters={
            "key": "value"
        }
    )
    Rule.sagemaker(
        base_config=rule_configs.built_in_rule_name(),
        rule_parameters={
            "key": "value"
        }
    )
    collections_to_save=[
        CollectionConfig(
            name="tensor_collection_name",
            parameters={
                "key": "value"
            }
        )
    ]
]
```

To find available keys for the `rule_parameters` parameter, see the parameter description tables.

Sample rule configuration codes are provided for each built-in rule below the parameter description tables.

- For a full instruction and examples of using the Debugger built-in rules, see [Debugger Built-in Rules Example Code \(p. 1612\)](#).
- For a full instruction of using the built-in rules with the low-level SageMaker API operations, see [Configure Debugger Using Amazon SageMaker API \(p. 1615\)](#).

## ProfilerReport

The ProfilerReport rule invokes all of the built-in rules for monitoring and profiling. It creates a profiling report and updates when the individual rules are triggered. You can download a comprehensive profiling report while a training job is running or after the training job is complete. You can adjust the rule parameter values to customize sensitivity of the built-in monitoring and profiling rules. The following example code shows the basic format to adjust the built-in rule parameters through the ProfilerReport rule.

```
rules=[
    ProfilerRule.sagemaker(
        rule_configs.ProfilerReport(
            <BuiltInRuleName>_<parameter_name> = value
        )
    )
]
```

]

If you trigger this ProfilerReport rule without any customized parameter as shown in the following example code, then the ProfilerReport rule triggers all of the built-in rules for monitoring and profiling with their default parameter values.

```
rules=[ProfilerRule.sagemaker(rule_configs.ProfilerReport())]
```

The following example code shows how to specify and adjust the CPUBottleneck rule's `cpu_threshold` parameter and the IOBottleneck rule's `threshold` parameter.

```
rules=[
    ProfilerRule.sagemaker(
        rule_configs.ProfilerReport(
            CPUBottleneck_cpu_threshold = 90,
            IOBottleneck_threshold = 90
        )
    )
]
```

### Parameter Descriptions for the OverallSystemUsage Rule

Parameter Name	Description
<code>base_trial</code>	<p>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.</p> <p><b>Required</b></p> <p>Valid values: String</p>
<code>&lt;BuiltInRuleName&gt;_&lt;parameter_name&gt;</code>	<p>Customizable parameter to adjust thresholds of other built-in monitoring and profiling rules.</p> <p><b>Optional</b></p> <p>Default value: None</p>

## BatchSize

The BatchSize rule helps detect if GPU is underutilized due to a small batch size. To detect this issue, this rule monitors the average CPU utilization, GPU utilization, and GPU memory utilization. If utilization on CPU, GPU, and GPU memory is low on average, it may indicate that the training job can either run on a smaller instance type or can run with a bigger batch size. This analysis does not work for frameworks that heavily overallocate memory. However, increasing the batch size can lead to processing or data loading bottlenecks because more data preprocessing time is required in each iteration.

### Parameter Descriptions for the BatchSize Rule

Parameter Name	Description
<code>base_trial</code>	<p>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.</p> <p><b>Required</b></p>

<b>Parameter Name</b>	<b>Description</b>
	Valid values: String
cpu_threshold_p95	<p>Defines the threshold for 95th quantile of CPU utilization in percentage.</p> <p><b>Optional</b></p> <p>Valid values: Integer</p> <p>Default value: 70 (in percentage)</p>
gpu_threshold_p95	<p>Defines the threshold for 95th quantile of GPU utilization in percentage.</p> <p><b>Optional</b></p> <p>Valid values: Integer</p> <p>Default value: 70 (in percentage)</p>
gpu_memory_threshold_p95	<p>Defines the threshold for 95th quantile of GPU memory utilization in percentage.</p> <p><b>Optional</b></p> <p>Valid values: Integer</p> <p>Default values: 70 (in percentage)</p>
patience	<p>Defines the number of data points to skip until the rule starts evaluation. The first several steps of training jobs usually show high volume of data processes, so keep the rule patient and prevent it from being invoked too soon with a given number of profiling data that you specify with this parameter.</p> <p><b>Optional</b></p> <p>Valid values: Integer</p> <p>Default values: 100</p>
window	<p>Window size for computing quantiles.</p> <p><b>Optional</b></p> <p>Valid values: Integer</p> <p>Default values: 500</p>
scan_interval_us	<p>Time interval that timeline files are scanned.</p> <p><b>Optional</b></p> <p>Valid values: Integer</p> <p>Default values: 6000000 (in microseconds)</p>

## CPUBottleneck

The CPUBottleneck rule helps detect if GPU is underutilized due to CPU bottlenecks. Rule returns True if number of CPU bottlenecks exceeds a predefined threshold.

### Parameter Descriptions for the CPUBottleneck Rule

Parameter Name	Description
<code>base_trial</code>	<p>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.</p> <p><b>Required</b></p> <p>Valid values: String</p>
<code>threshold</code>	<p>Defines the threshold for proportion of bottlenecked time to the total training time. If the proportion exceeds the percentage specified to the threshold parameter, the rule switches the rule status to True.</p> <p><b>Optional</b></p> <p>Valid values: Integer</p> <p>Default value: 50 (in percentage)</p>
<code>gpu_threshold</code>	<p>A threshold that defines low GPU utilization.</p> <p><b>Optional</b></p> <p>Valid values: Integer</p> <p>Default value: 10 (in percentage)</p>
<code>cpu_threshold</code>	<p>A threshold that defines high CPU utilization.</p> <p><b>Optional</b></p> <p>Valid values: Integer</p> <p>Default values: 90 (in percentage)</p>
<code>patience</code>	<p>Defines the number of data points to skip until the rule starts evaluation. The first several steps of training jobs usually show high volume of data processes, so keep the rule patient and prevent it from being invoked too soon with a given number of profiling data that you specify with this parameter.</p> <p><b>Optional</b></p> <p>Valid values: Integer</p> <p>Default values: 100</p>
<code>scan_interval_us</code>	Time interval with which timeline files are scanned.

Parameter Name	Description
	<b>Optional</b>  Valid values: Integer  Default values: 60000000 (in microseconds)

## GPUMemoryIncrease

The GPUMemoryIncrease rule helps detect a large increase in memory usage on GPUs.

### Parameter Descriptions for the GPUMemoryIncrease Rule

Parameter Name	Description
base_trial	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.  <b>Required</b>  Valid values: String  Default value: N/A
increase	Defines the threshold for absolute memory increase.  <b>Optional</b>  Valid values: Integer  Default value: 10 (in percentage)
patience	Defines the number of data points to skip until the rule starts evaluation. The first several steps of training jobs usually show high volume of data processes, so keep the rule patient and prevent it from being invoked too soon with a given number of profiling data that you specify with this parameter.  <b>Optional</b>  Valid values: Integer  Default values: 100
window	Window size for computing quantiles.  <b>Optional</b>  Valid values: Integer  Default values: 500
scan_interval_us	Time interval that timeline files are scanned.  <b>Optional</b>  Valid values: Integer

Parameter Name	Description
	Default values: 60000000 (in microseconds)

## IOBottleneck

This rule helps to detect if GPU is underutilized due to data IO bottlenecks. Rule returns True if number of IO bottlenecks exceeds a predefined threshold.

### Parameter Descriptions for the IOBottleneck Rule

Parameter Name	Description
base_trial	<p>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.</p> <p><b>Required</b></p> <p>Valid values: String</p>
threshold	<p>Defines the threshold when Rule to return True.</p> <p><b>Optional</b></p> <p>Valid values: Integer</p> <p>Default value: 50 (in percentage)</p>
gpu_threshold	<p>A threshold that defines when GPU is considered underutilized.</p> <p><b>Optional</b></p> <p>Valid values: Integer</p> <p>Default value: 70 (in percentage)</p>
io_threshold	<p>A threshold that defines high IO wait time.</p> <p><b>Optional</b></p> <p>Valid values: Integer</p> <p>Default values: 50 (in percentage)</p>
patience	<p>Defines the number of data points to skip until the rule starts evaluation. The first several steps of training jobs usually show high volume of data processes, so keep the rule patient and prevent it from being invoked too soon with a given number of profiling data that you specify with this parameter.</p> <p><b>Optional</b></p> <p>Valid values: Integer</p> <p>Default values: 1000</p>

Parameter Name	Description
scan_interval_us	<p>Time interval that timeline files are scanned.</p> <p><b>Optional</b></p> <p>Valid values: Integer</p> <p>Default values: 60000000 (in microseconds)</p>

## LoadBalancing

The LoadBalancing rule helps detect issues in workload balancing among multiple GPUs.

### Parameter Descriptions for the LoadBalancing Rule

Parameter Name	Description
base_trial	<p>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.</p> <p><b>Required</b></p> <p>Valid values: String</p>
threshold	<p>Defines the workload percentage.</p> <p><b>Optional</b></p> <p>Valid values: Integer</p> <p>Default value: 0 . 5 (unitless proportion)</p>
patience	<p>Defines the number of data points to skip until the rule starts evaluation. The first several steps of training jobs usually show high volume of data processes, so keep the rule patient and prevent it from being invoked too soon with a given number of profiling data that you specify with this parameter.</p> <p><b>Optional</b></p> <p>Valid values: Integer</p> <p>Default values: 10</p>
scan_interval_us	<p>Time interval that timeline files are scanned.</p> <p><b>Optional</b></p> <p>Valid values: Integer</p> <p>Default values: 60000000 (in microseconds)</p>

## LowGPUUtilization

The LowGPUUtilization rule helps detect if GPU utilization is low or suffers from fluctuations. This is checked for each GPU on each worker. Rule returns True if 95th quantile is below threshold\_p95 which indicates underutilization. Rule returns true if 95th quantile is above threshold\_p95 and 5th quantile is below threshold\_p5 which indicates fluctuations.

### Parameter Descriptions for the LowGPUUtilization Rule

Parameter Name	Description
<code>base_trial</code>	<p>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.</p> <p><b>Required</b></p> <p>Valid values: String</p>
<code>threshold_p95</code>	<p>A threshold for 95th quantile below which GPU is considered to be underutilized.</p> <p><b>Optional</b></p> <p>Valid values: Integer</p> <p>Default value: 70 (in percentage)</p>
<code>threshold_p5</code>	<p>A threshold for 5th quantile. Default is 10 percent.</p> <p><b>Optional</b></p> <p>Valid values: Integer</p> <p>Default values: 10 (in percentage)</p>
<code>patience</code>	<p>Defines the number of data points to skip until the rule starts evaluation. The first several steps of training jobs usually show high volume of data processes, so keep the rule patient and prevent it from being invoked too soon with a given number of profiling data that you specify with this parameter.</p> <p><b>Optional</b></p> <p>Valid values: Integer</p> <p>Default values: 1000</p>
<code>window</code>	<p>Window size for computing quantiles.</p> <p><b>Optional</b></p> <p>Valid values: Integer</p> <p>Default values: 500</p>
<code>scan_interval_us</code>	<p>Time interval that timeline files are scanned.</p> <p><b>Optional</b></p>

Parameter Name	Description
	Valid values: Integer
	Default values: 60000000 (in microseconds)

## OverallSystemUsage

The OverallSystemUsage rule measures overall system usage per worker node. The rule currently only aggregates values per node and computes their percentiles.

### Parameter Descriptions for the OverallSystemUsage Rule

Parameter Name	Description
<code>base_trial</code>	<p>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.</p> <p><b>Required</b></p> <p>Valid values: String</p>
<code>scan_interval_us</code>	<p>Time interval to scan timeline files.</p> <p><b>Optional</b></p> <p>Valid values: Integer</p> <p>Default values: 60000000 (in microseconds)</p>

## MaxInitializationTime

The MaxInitializationTime rule helps detect if the training initialization is taking too much time. The rule waits until the first step is available.

### Parameter Descriptions for the MaxInitializationTime Rule

Parameter Name	Description
<code>base_trial</code>	<p>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.</p> <p><b>Required</b></p> <p>Valid values: String</p>
<code>threshold</code>	<p>Defines the threshold in minutes to wait for the first step to become available.</p> <p><b>Optional</b></p> <p>Valid values: Integer</p> <p>Default value: 20 (in minutes)</p>

Parameter Name	Description
scan_interval_us	<p>Time interval with which timeline files are scanned.</p> <p><b>Optional</b></p> <p>Valid values: Integer</p> <p>Default values: 60000000 (in microseconds)</p>

## OverallFrameworkMetrics

The OverallFrameworkMetrics rule summarizes the time spent on framework metrics, such as forward and backward pass, and data loading.

### Parameter Descriptions for the OverallFrameworkMetrics Rule

Parameter Name	Description
base_trial	<p>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.</p> <p><b>Required</b></p> <p>Valid values: String</p>
scan_interval_us	<p>Time interval to scan timeline files.</p> <p><b>Optional</b></p> <p>Valid values: Integer</p> <p>Default values: 60000000 (in microseconds)</p>

## StepOutlier

The StepOutlier rule helps detect outliers in step durations. This rule returns `True` if there are outliers with step durations larger than `stddev` sigmas of the entire step durations in a time range.

### Parameter Descriptions for the StepOutlier Rule

Parameter Name	Description
base_trial	<p>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.</p> <p><b>Required</b></p> <p>Valid values: String</p>
stddev	<p>Defines a factor by which to multiply the standard deviation. For example, the rule is invoked by default when a step duration is larger or smaller than 5 times the standard deviation.</p>

Parameter Name	Description
	<b>Optional</b> Valid values: Integer Default value: 5 (in minutes)
mode	Mode under which steps have been saved and on which Rule should run on. Per default rule will run on steps from EVAL and TRAIN phase <b>Optional</b> Valid values: Integer Default value: 5 (in minutes)
n_outliers	How many outliers to ignore before rule returns True <b>Optional</b> Valid values: Integer Default value: 10
scan_interval_us	Time interval with which timeline files are scanned. <b>Optional</b> Valid values: Integer Default values: 60000000 (in microseconds)

## CreateXgboostReport

The CreateXgboostReport rule collects output tensors from an XGBoost training job and autogenerated a comprehensive training report. You can download a comprehensive profiling report while a training job is running or after the training job is complete, and check progress of training or the final result of the training job. The CreateXgboostReport rule collects the following output tensors by default:

- `hyperparameters` – Saves at the first step
- `metrics` – Saves loss and accuracy every 5 steps
- `feature_importance` – Saves every 5 steps
- `predictions` – Saves every 5 steps
- `labels` – Saves every 5 steps

### Parameter Descriptions for the CreateXgboostReport Rule

Parameter Name	Description
<code>base_trial</code>	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.

Parameter Name	Description
	<b>Required</b>  Valid values: String

```

rules=[
    Rule.sagemaker(
        rule_configs.create_xgboost_report()
    )
]

```

## DeadRelu

This rule detects when the percentage of rectified linear unit (ReLU) activation functions in a trial are considered dead because their activation activity has dropped below a threshold. If the percent of inactive ReLUs in a layer is greater than the `threshold_layer` value of inactive ReLUs, the rule returns `True`.

### Parameter Descriptions for the DeadRelu Rule

Parameter Name	Description
<code>base_trial</code>	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.  <b>Required</b>  Valid values: String
<code>tensor_regex</code>	A list of regex patterns used to restrict this comparison to specific scalar-valued tensors. The rule inspects only the tensors that match the regex patterns specified in the list. If no patterns are passed, the rule compares all tensors gathered in the trials by default. Only scalar-valued tensors can be matched.  <b>Optional</b>  Valid values: List of strings or a comma-separated string  Default value: ".*relu_output"
<code>threshold_inactivity</code>	Defines a level of activity below which a ReLU is considered to be dead. A ReLU might be active in the beginning of a trial and then slowly die during the training process. If the ReLU is active less than the <code>threshold_inactivity</code> , it is considered to be dead.  <b>Optional</b>  Valid values: Float  Default values: 1.0 (in percentage)

Parameter Name	Description
threshold_layer	<p>Returns <code>True</code> if the percentage of inactive ReLUs in a layer is greater than <code>threshold_layer</code>.</p> <p>Returns <code>False</code> if the percentage of inactive ReLUs in a layer is less than <code>threshold_layer</code>.</p> <p><b>Optional</b></p> <p>Valid values: Float</p> <p>Default values: 50.0 (in percentage)</p>

```

built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.dead_relu(),
        rule_parameters={
            "tensor_regex": ".*relu_output|.*ReLU_output",
            "threshold_inactivity": "1.0",
            "threshold_layer": "50.0"
        }
    ),
    collections_to_save=[
        CollectionConfig(
            name="custom_relu_collection",
            parameters={
                "include_regex": ".*relu_output|.*ReLU_output",
                "save_interval": "500"
            }
        )
    ]
]

```

For an example of how to configure and deploy a built-in rule, see [Configure Debugger Built-in Rules \(p. 1608\)](#).

**Note**

This rule is not available for the XGBoost algorithm.

## ExplodingTensor

This rule detects whether the tensors emitted during training have non-finite values, either infinite or NaN (not a number). If a non-finite value is detected, the rule returns `True`.

### Parameter Descriptions for the ExplodingTensor Rule

Parameter Name	Description
base_trial	<p>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.</p> <p><b>Required</b></p> <p>Valid values: String</p>
collection_names	The list of collection names whose tensors the rule inspects.

Parameter Name	Description
	<p><b>Optional</b></p> <p>Valid values: String</p> <p>Default value: None</p>
<code>tensor_regex</code>	<p>A list of regex patterns used to restrict this comparison to specific scalar-valued tensors. The rule inspects only the tensors that match the regex patterns specified in the list. If no patterns are passed, the rule compares all tensors gathered in the trials by default. Only scalar-valued tensors can be matched.</p>
	<p><b>Optional</b></p> <p>Valid values: String</p> <p>Default value: None</p>
<code>only_nan</code>	<p>True to monitor the <code>base_trial</code> tensors only for NaN values and not for infinity.</p> <p>False to treat both NaN and infinity as exploding values and to monitor for both.</p>
	<p><b>Optional</b></p> <p>Default value: False</p>

```
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.exploding_tensor(),
        rule_parameters={
            "tensor_regex": ".*\ngradient",
            "only_nan": "False"
        }
    ),
    collections_to_save=[
        CollectionConfig(
            name="gradients",
            parameters={
                "save_interval": "500"
            }
        )
    ]
]
```

For an example of how to configure and deploy a built-in rule, see [Configure Debugger Built-in Rules \(p. 1608\)](#).

## Note

This rule is not available for the XGBoost algorithm.

# PoorWeightInitialization

This rule detects if your model parameters have been poorly initialized.

Good initialization breaks the symmetry of the weights and gradients in a neural network and maintains commensurate activation variances across layers. Otherwise, the neural network doesn't learn effectively. Initializers like Xavier aim to keep variance constant across activations, which is especially relevant for training very deep neural nets. Too small an initialization can lead to vanishing gradients. Too large an initialization can lead to exploding gradients. This rule checks the variance of activation inputs across layers, the distribution of gradients, and the loss convergence for the initial steps to determine if a neural network has been poorly initialized.

### Parameter Descriptions for the PoorWeightInitialization Rule

Parameter Name	Description
<code>base_trial</code>	<p>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.</p> <p><b>Required</b></p> <p>Valid values: String</p>
<code>activation_inputs_regex</code>	<p>A list of regex patterns used to restrict this comparison to specific scalar-valued tensors. The rule inspects only the tensors that match the regex patterns specified in the list. If no patterns are passed, the rule compares all tensors gathered in the trials by default. Only scalar-valued tensors can be matched.</p> <p><b>Optional</b></p> <p>Valid values: String</p> <p>Default value: ". *relu_input"</p>
<code>threshold</code>	<p>If the ratio between minimum and maximum variance of weights per layer exceeds the threshold at a step, the rule returns <code>True</code>.</p> <p><b>Optional</b></p> <p>Valid values: Float</p> <p>Default value: 10 . 0</p>
<code>distribution_range</code>	<p>If the minimum difference between 5th and 95th percentiles of the gradient distribution is less than the <code>distribution_range</code>, the rule returns <code>True</code>.</p> <p><b>Optional</b></p> <p>Valid values: Float</p> <p>Default value: 0 . 001</p>
<code>patience</code>	<p>The number of steps to wait until the loss is considered to be no longer decreasing.</p> <p><b>Optional</b></p> <p>Valid values: Integer</p>

Parameter Name	Description
	Default value: 5
steps	<p>The number of steps this rule analyzes. You typically need to check only the first few iterations.</p> <p><b>Optional</b></p> <p>Valid values: Float</p> <p>Default value: 10</p>

```

built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.poor_weight_initialization(),
        rule_parameters={
            "activation_inputs_regex": ".*relu_input|.*ReLU_input",
            "threshold": "10.0",
            "distribution_range": "0.001",
            "patience": "5",
            "steps": "10"
        },
        collections_to_save=[
            CollectionConfig(
                name="custom_relu_collection",
                parameters={
                    "include_regex": ".*relu_input|.*ReLU_input",
                    "save_interval": "500"
                }
            )
        ]
    )
]

```

For an example of how to configure and deploy a built-in rule, see [Configure Debugger Built-in Rules \(p. 1608\)](#).

**Note**

This rule is not available for the XGBoost algorithm.

## SaturatedActivation

This rule detects if the tanh and sigmoid activation layers are becoming saturated. An activation layer is saturated when the input of the layer is close to the maximum or minimum of the activation function. The minimum and maximum of the tanh and sigmoid activation functions are defined by their respective `min_threshold` and `max_threshold` values. If the activity of a node drops below the `threshold_inactivity` percentage, it is considered saturated. If more than a `threshold_layer` percent of the nodes are saturated, the rule returns `True`.

### Parameter Descriptions for the SaturatedActivation Rule

Parameter Name	Description
base_trial	<p>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.</p> <p><b>Required</b></p>

Parameter Name	Description
	Valid values: String
<code>collection_names</code>	<p>The list of collection names whose tensors the rule inspects.</p> <p><b>Optional</b></p> <p>Valid values: List of strings or a comma-separated string</p> <p>Default value: None</p>
<code>tensor_regex</code>	<p>A list of regex patterns used to restrict this comparison to specific scalar-valued tensors. The rule inspects only the tensors that match the regex patterns specified in the list. If no patterns are passed, the rule compares all tensors gathered in the trials by default. Only scalar-valued tensors can be matched.</p> <p><b>Optional</b></p> <p>Valid values: String</p> <p>Default value: ".*tanh_input .*sigmoid_input".</p>
<code>threshold_tanh_min</code>	<p>The minimum and maximum thresholds that define the extremes of the input for a tanh activation function, defined as: (<code>min_threshold</code>, <code>max_threshold</code>). The default values are determined based on a vanishing gradient threshold of 0.0000001.</p> <p><b>Optional</b></p> <p>Valid values: Float</p> <p>Default values: -9 . 4999</p>
<code>threshold_tanh_max</code>	<p>The minimum and maximum thresholds that define the extremes of the input for a tanh activation function, defined as: (<code>min_threshold</code>, <code>max_threshold</code>). The default values are determined based on a vanishing gradient threshold of 0.0000001.</p> <p><b>Optional</b></p> <p>Valid values: Float</p> <p>Default values: 9 . 4999</p>

Parameter Name	Description
threshold_sigmoid_min	<p>The minimum and maximum thresholds that define the extremes of the input for a sigmoid activation function, defined as: (<code>min_threshold</code>, <code>max_threshold</code>). The default values are determined based on a vanishing gradient threshold of 0.0000001.</p> <p><b>Optional</b></p> <p>Valid values: Float</p> <p>Default values: -23</p>
threshold_sigmoid_max	<p>The minimum and maximum thresholds that define the extremes of the input for a sigmoid activation function, defined as: (<code>min_threshold</code>, <code>max_threshold</code>). The default values are determined based on a vanishing gradient threshold of 0.0000001.</p> <p><b>Optional</b></p> <p>Valid values: Float</p> <p>Default values: 16 . 99999</p>
threshold_inactivity	<p>The percentage of inactivity below which the activation layer is considered to be saturated. The activation might be active in the beginning of a trial and then slowly become less active during the training process.</p> <p><b>Optional</b></p> <p>Valid values: Float</p> <p>Default values: 1 . 0</p>
threshold_layer	<p>Returns <code>True</code> if the number of saturated activations in a layer is greater than the <code>threshold_layer</code> percentage.</p> <p>Returns <code>False</code> if the number of saturated activations in a layer is less than the <code>threshold_layer</code> percentage.</p> <p><b>Optional</b></p> <p>Valid values: Float</p> <p>Default values: 50 . 0</p>

```

built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.saturated_activation(),
        rule_parameters={
            "tensor_regex": ".*tanh_input|.*sigmoid_input",

```

```

        "threshold_tanh_min": "-9.4999",
        "threshold_tanh_max": "9.4999",
        "threshold_sigmoid_min": "-23",
        "threshold_sigmoid_max": "16.99999",
        "threshold_inactivity": "1.0",
        "threshold_layer": "50.0"
    },
    collections_to_save=[
        CollectionConfig(
            name="custom_activations_collection",
            parameters={
                "include_regex": ".*tanh_input/.*sigmoid_input"
                "save_interval": "500"
            }
        )
    ]
]

```

For an example of how to configure and deploy a built-in rule, see [Configure Debugger Built-in Rules \(p. 1608\)](#).

**Note**

This rule is not available for the XGBoost algorithm.

## VanishingGradient

This rule detects if the gradients in a trial become extremely small or drop to a zero magnitude. If the mean of the absolute values of the gradients drops below a specified threshold, the rule returns `True`.

### Parameters Descriptions for the VanishingGradient Rule

Parameter Name	Description
<code>base_trial</code>	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.  <b>Required</b>  Valid values: String
<code>threshold</code>	The value at which the gradient is determined to be vanishing.  <b>Optional</b>  Valid values: Float  Default value: 0.0000001.

```

built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.vanishing_gradient(),
        rule_parameters={
            "threshold": "0.0000001"
        },
        collections_to_save=[
            CollectionConfig(
                name="gradients",

```

```

        parameters={
            "save_interval": "500"
        }
    ]
}
]
```

For an example of how to configure and deploy a built-in rule, see [Configure Debugger Built-in Rules \(p. 1608\)](#).

**Note**

This rule is not available for the XGBoost algorithm.

## WeightUpdateRatio

This rule keeps track of the ratio of updates to weights during training and detects if that ratio gets too large or too small. If the ratio of updates to weights is larger than the `large_threshold` value or if this ratio is smaller than `small_threshold`, the rule returns `True`.

Conditions for training are best when the updates are commensurate to gradients. Excessively large updates can push the weights away from optimal values, and very small updates result in very slow convergence. This rule requires weights to be available for two training steps, and `train.save_interval` needs to be set equal to `num_steps`.

### Parameter Descriptions for the WeightUpdateRatio Rule

Parameter Name,	Description
<code>base_trial</code>	<p>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.</p> <p><b>Required</b></p> <p>Valid values: String</p>
<code>num_steps</code>	<p>The number of steps across which the rule checks to determine if the tensor has changed.</p> <p>The number of steps across which you want to compare the weight ratios. If you pass no value, the rule runs by default against the current step and the immediately previous saved step. If you override the default by passing a value for this parameter, the comparison is done between weights at step <code>s</code> and at a step <math>\geq s - num\_steps</math>.</p> <p><b>Optional</b></p> <p>Valid values: Integer</p> <p>Default value: None</p>
<code>large_threshold</code>	<p>The maximum value that the ratio of updates to weight can take before the rule returns <code>True</code>.</p> <p><b>Optional</b></p>

<b>Parameter Name,</b>	<b>Description</b>
	Valid values: Float  Default value: 10 . 0
small_threshold	The minimum value that the ratio of updates to weight can take, below which the rule returns True.  <b>Optional</b>  Valid values: Float  Default value: 0 . 00000001
epsilon	A small constant used to ensure that Debugger does not divide by zero when computing the ratio updates to weigh.  <b>Optional</b>  Valid values: Float  Default value: 0 . 000000001

```

built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.weight_update_ratio(),
        rule_parameters={
            "num_steps": "100",
            "large_threshold": "10.0",
            "small_threshold": "0.00000001",
            "epsilon": "0.000000001"
        },
        collections_to_save=[
            CollectionConfig(
                name="weights",
                parameters={
                    "train.save_interval": "100"
                }
            )
        ]
    )
]

```

For an example of how to configure and deploy a built-in rule, see [Configure Debugger Built-in Rules \(p. 1608\)](#).

**Note**

This rule is not available for the XGBoost algorithm.

## AllZero

This rule detects if all or a specified percentage of the tensor values are zero.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm. You must specify either the `collection_names` or `tensor_regex` parameter. If both the parameters are specified, the rule inspects the union of tensors from both sets.

For an example of how to configure and deploy a built-in rule, see [Configure Debugger Built-in Rules \(p. 1608\)](#).

### Parameters Descriptions for the AllZero Rule

Parameter Name	Description
<code>base_trial</code>	<p>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.</p> <p><b>Required</b></p> <p>Valid values: String</p>
<code>collection_names</code>	<p>The list of collection names whose tensors the rule inspects.</p> <p><b>Optional</b></p> <p>Valid values: List of strings or a comma-separated string</p> <p>Default value: None</p>
<code>tensor_regex</code>	<p>A list of regex patterns used to restrict this comparison to specific scalar-valued tensors. The rule inspects only the tensors that match the regex patterns specified in the list. If no patterns are passed, the rule compares all tensors gathered in the trials by default. Only scalar-valued tensors can be matched.</p> <p><b>Optional</b></p> <p>Valid values: List of strings or a comma-separated string</p> <p>Default value: None</p>
<code>threshold</code>	<p>Specifies the percentage of values in the tensor that needs to be zero for this rule to be invoked.</p> <p><b>Optional</b></p> <p>Valid values: Float</p> <p>Default value: 100 (in percentage)</p>

```

built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.all_zero(),
        rule_parameters={
            "tensor_regex": ".*",
            "threshold": "100"
        },
        collections_to_save=[
            CollectionConfig(
                name="all",
                parameters={

```

```

        "save_interval": "500"
    }
}
]
```

## ClassImbalance

This rule measures sampling imbalances between classes and throws errors if the imbalance exceeds a threshold or if too many mispredictions for underrepresented classes occur as a result of the imbalance.

Classification models require well-balanced classes in the training dataset or a proper weighting/sampling of classes during training. The rule performs the following checks:

- It counts the occurrences per class. If the ratio of number of samples between smallest and largest class is larger than the `threshold_imbalance`, an error is thrown.
- It checks the prediction accuracy per class. If resampling or weighting has not been correctly applied, then the model can reach high accuracy for the class with many training samples, but low accuracy for the classes with few training samples. If a fraction of mispredictions for a certain class is above `threshold_misprediction`, an error is thrown.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see [Configure Debugger Built-in Rules \(p. 1608\)](#).

### Parameter Descriptions for the ClassImbalance Rule

Parameter Name	Description
<code>base_trial</code>	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.  <b>Required</b>  Valid values: String
<code>threshold_imbalance</code>	The acceptable imbalance between the number of samples in the smallest class and in the largest class. Exceeding this threshold value throws an error.  <b>Optional</b>  Valid values: Float  Default value: 10
<code>threshold_misprediction</code>	A limit on the fraction of mispredictions allowed for each class. Exceeding this threshold throws an error. The underrepresented classes are most at risk of crossing this threshold.  <b>Optional</b>  Valid values: Float

Parameter Name	Description
	Default value: 0 . 7
<code>samples</code>	The number of labels that have to be processed before an imbalance is evaluated. The rule might not be triggered until it has seen sufficient samples across several steps. The more classes that your dataset contains, the larger this sample number should be.
	<b>Optional</b>
	Valid values: Integer
	Default value: 500 (assuming a dataset like MNIST with 10 classes)
<code>argmax</code>	If <code>True</code> , <code>np.argmax</code> is applied to the prediction tensor. Required when you have a vector of probabilities for each class. It is used to determine which class has the highest probability.
	<b>Conditional</b>
	Valid values: Boolean
	Default value: <code>False</code>
<code>labels_regex</code>	The name of the tensor that contains the labels.
	<b>Optional</b>
	Valid values: String
	Default value: ". *labels"
<code>predictions_regex</code>	The name of the tensor that contains the predictions.
	<b>Optional</b>
	Valid values: String
	Default value: ". *predictions"

```

built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.class_imbalance(),
        rule_parameters={
            "threshold_imbalance": "10",
            "threshold_misprediction": "0.7",
            "samples": "500",
            "argmax": "False",
            "labels_regex": ". *labels",
            "predictions_regex": ". *predictions"
        },
        collections_to_save=[
            CollectionConfig(
                name="custom_output_collection",

```

```

        parameters={
            "include_regex": ".*labels/.*predictions",
            "save_interval": "500"
        }
    ]
]
]
```

## LossNotDecreasing

This rule detects when the loss is not decreasing in value at an adequate rate. These losses must be scalars.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm. You must specify either the `collection_names` or `tensor_regex` parameter. If both the parameters are specified, the rule inspects the union of tensors from both sets.

For an example of how to configure and deploy a built-in rule, see [Configure Debugger Built-in Rules \(p. 1608\)](#).

### Parameter Descriptions for the LossNotDecreasing Rule

Parameter Name	Description
<code>base_trial</code>	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.  <b>Required</b>  Valid values: String
<code>collection_names</code>	The list of collection names whose tensors the rule inspects.  <b>Optional</b>  Valid values: List of strings or a comma-separated string  Default value: None
<code>tensor_regex</code>	A list of regex patterns that is used to restrict this comparison to specific scalar-valued tensors. The rule inspects only the tensors that match the regex patterns specified in the list. If no patterns are passed, the rule compares all tensors gathered in the trials by default. Only scalar-valued tensors can be matched.  <b>Optional</b>  Valid values: List of strings or a comma-separated string  Default value: None
<code>use_losses_collection</code>	If set to <code>True</code> , looks for losses in the collection named "losses" when the collection is present.

Parameter Name	Description
	<b>Optional</b> Valid values: Boolean Default value: True
<code>num_steps</code>	The minimum number of steps after which the rule checks if the loss has decreased. Rule evaluation happens every <code>num_steps</code> . The rule compares the loss for this step with the loss at a step which is at least <code>num_steps</code> behind the current step. For example, suppose that the loss is being saved every three steps, but <code>num_steps</code> is set to 10. At step 21, loss for step 21 is compared with loss for step 9. The next step at which loss is checked is step 33, because ten steps after step 21 is step 31, and at step 31 and step 32 loss is not saved. <b>Optional</b> Valid values: Integer Default value: 10
<code>diff_percent</code>	The minimum percentage difference by which the loss should decrease between <code>num_steps</code> . <b>Optional</b> Valid values: <code>0 . 0 &lt; float &lt; 100</code> Default value: <code>0 . 1</code> (in percentage)
<code>increase_threshold_percent</code>	The maximum threshold percent that loss is allowed to increase in case loss has been increasing <b>Optional</b> Valid values: <code>0 &lt; float &lt; 100</code> Default value: <code>5</code> (in percentage)
<code>mode</code>	The name of the Debugger mode to query tensor values for rule checking. If this is not passed, the rule checks in order by default for the mode <code>EVAL</code> , then <code>mode . TRAIN</code> , and then <code>mode . GLOBAL</code> . <b>Optional</b> Valid values: String ( <code>EVAL</code> , <code>TRAIN</code> , or <code>GLOBAL</code> ) Default value: <code>GLOBAL</code>

```
built_in_rules = [
```

```

Rule.sagemaker(
    base_config=rule_configs.loss_not_decreasing(),
    rule_parameters={
        "tensor_regex": ".*",
        "use_losses_collection": "True",
        "num_steps": "10",
        "diff_percent": "0.1",
        "increase_threshold_percent": "5",
        "mode": "GLOBAL"
    },
    collections_to_save=[
        CollectionConfig(
            name="losses",
            parameters={
                "save_interval": "500"
            }
        )
    ]
)
]

```

## Overfit

This rule detects if your model is being overfit to the training data by comparing the validation and training losses.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see [Configure Debugger Built-in Rules \(p. 1608\)](#).

**Note**

A standard way to prevent overfitting is to regularize your model.

### Parameter Descriptions for the Overfit Rule

Parameter Name	Description
<code>base_trial</code>	<p>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.</p> <p><b>Required</b></p> <p>Valid values: String</p>
<code>tensor_regex</code>	<p>A list of regex patterns used to restrict this comparison to specific scalar-valued tensors. The rule inspects only the tensors that match the regex patterns specified in the list. If no patterns are passed, the rule compares all tensors gathered in the trials by default. Only scalar-valued tensors can be matched.</p> <p><b>Optional</b></p> <p>Valid values: List of strings or a comma-separated string</p> <p>Default value: None</p>

Parameter Name	Description
<code>start_step</code>	<p>The step from which to start comparing the validation and training loss.</p> <p><b>Optional</b></p> <p>Valid values: Integer</p> <p>Default value: 0</p>
<code>patience</code>	<p>The number of steps for which the <code>ratio_threshold</code> is allowed to exceed the value set before the model is considered to be overfit.</p> <p><b>Optional</b></p> <p>Valid values: Integer</p> <p>Default value: 1</p>
<code>ratio_threshold</code>	<p>The maximum ratio of the difference between the mean validation loss and mean training loss to the mean training loss. If this threshold is exceeded for a patience number of steps, the model is being overfit and the rule returns <code>True</code>.</p> <p><b>Optional</b></p> <p>Valid values: Float</p> <p>Default value: 0.1</p>

```

built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.overfit(),
        rule_parameters={
            "tensor_regex": ".*",
            "start_step": "0",
            "patience": "1",
            "ratio_threshold": "0.1"
        },
        collections_to_save=[
            CollectionConfig(
                name="losses",
                parameters={
                    "train.save_interval": "100",
                    "eval.save_interval": "10"
                }
            )
        ]
    )
]

```

## Overtraining

This rule detects if a model is being overtrained. After a number of training iterations on a well-behaved model (both training and validation loss decrease), the model approaches to a minimum of the loss function and does not improve anymore. If the model continues training it can happen that validation

loss starts increasing, because the model starts overfitting. This rule sets up thresholds and conditions to determine if the model is not improving, and prevents overfitting problems due to overtraining.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see [Configure Debugger Built-in Rules \(p. 1608\)](#).

**Note**

Overtraining can be avoided by early stopping. For information on early stopping, see [Stop Training Jobs Early \(p. 1764\)](#). For an example that shows how to use spot training with Debugger, see [Enable Spot Training with Amazon SageMaker Debugger](#).

### Parameter Descriptions for the Overtraining Rule

Parameter Name	Description
base_trial	<p>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.</p> <p><b>Required</b></p> <p>Valid values: String</p>
patience_train	<p>The number of steps to wait before the training loss is considered to not to be improving anymore.</p> <p><b>Optional</b></p> <p>Valid values: Integer</p> <p>Default value: 5</p>
patience_validation	<p>The number of steps to wait before the validation loss is considered to not to be improving anymore.</p> <p><b>Optional</b></p> <p>Valid values: Integer</p> <p>Default value: 10</p>
delta	<p>The minimum threshold by how much the error should improve before it is considered as a new optimum.</p> <p><b>Optional</b></p> <p>Valid values: Float</p> <p>Default value: 0 . 01</p>

```

built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.overtraining(),
        rule_parameters={
            "patience_train": "5",
            "patience_validation": "10",

```

```

        "delta": "0.01"
    },
    collections_to_save:[
        CollectionConfig(
            name="losses",
            parameters={
                "save_interval": "500"
            }
        )
    ]
]

```

## SimilarAcrossRuns

This rule compares tensors gathered from a base trial with tensors from another trial.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see [Configure Debugger Built-in Rules \(p. 1608\)](#).

### Parameter Descriptions for the SimilarAcrossRuns Rule

Parameter Name	Description
base_trial	<p>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.</p> <p><b>Required</b></p> <p>Valid values: String</p>
other_trial	<p>A completed training job name whose tensors you want to compare to those tensors gathered from the current <code>base_trial</code>.</p> <p><b>Required</b></p> <p>Valid values: String</p>
collection_names	<p>The list of collection names whose tensors the rule inspects.</p> <p><b>Optional</b></p> <p>Valid values: List of strings or a comma-separated string</p> <p>Default value: None</p>
tensor_regex	<p>A list of regex patterns used to restrict this comparison to specific scalar-valued tensors. The rule inspects only the tensors that match the regex patterns specified in the list. If no patterns are passed, the rule compares all tensors gathered in the trials by default. Only scalar-valued tensors can be matched.</p>

Parameter Name	Description
	<b>Optional</b>  Valid values: List of strings or a comma-separated string  Default value: None

```

built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.similar_across_runs(),
        rule_parameters={
            "other_trial": "<specify-another-job-name>",
            "collection_names": "losses",
            "tensor_regex": ".*"
        },
        collections_to_save=[
            CollectionConfig(
                name="losses",
                parameters={
                    "save_interval": "500"
                }
            )
        ]
    )
]

```

## StalledTrainingRule

StalledTrainingRule detects if there is no progress made on training job, and stops the training job if the rule fires. This rule requires tensors to be periodically saved in a time interval defined by its `threshold` parameter. This rule keeps on monitoring for new tensors, and if no new tensor has been emitted for threshold interval rule gets fired.

### Parameter Descriptions for the StalledTrainingRule Rule

Parameter Name	Description
<code>base_trial</code>	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.  <b>Required</b>  Valid values: String
<code>threshold</code>	A threshold that defines by how much time in seconds the rule waits for a tensor output until it fires a stalled training issue. Default value is 1800 seconds.  <b>Optional</b>  Valid values: Integer  Default value: 1800
<code>stop_training_on_fire</code>	If set to <code>True</code> , watches if the base training job outputs tensors in " <code>threshold</code> " seconds.

Parameter Name	Description
	<b>Optional</b> Valid values: Boolean Default value: <code>False</code>
<code>training_job_name_prefix</code>	The prefix of base training job name. If <code>stop_training_on_fire</code> is true, the rule searches for SageMaker training jobs with this prefix in the same account. If there is an inactivity found, the rule takes a <code>StopTrainingJob</code> action. Note if there are multiple jobs found with same prefix, the rule skips termination. It is important that the prefix is set unique per each training job. <b>Optional</b> Valid values: String

```

built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.stalled_training_rule(),
        rule_parameters={
            "threshold": "1800",
            "stop_training_on_fire": "True",
            "training_job_name_prefix": "<specify-training-base-job-name>"
        },
        collections_to_save=[
            CollectionConfig(
                name="losses",
                parameters={
                    "save_interval": "500"
                }
            )
        ]
    )
]

```

## TensorVariance

This rule detects if you have tensors with very high or low variances. Very high or low variances in a tensor could lead to neuron saturation, which reduces the learning ability of the neural network. Very high variance in tensors can also eventually lead to exploding tensors. Use this rule to detect such issues early.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm. You must specify either the `collection_names` or `tensor_regex` parameter. If both the parameters are specified, the rule inspects the union of tensors from both sets.

For an example of how to configure and deploy a built-in rule, see [Configure Debugger Built-in Rules \(p. 1608\)](#).

## Parameter Descriptions for the TensorVariance Rule

Parameter Name	Description
<code>base_trial</code>	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.  <b>Required</b>  Valid values: String
<code>collection_names</code>	The list of collection names whose tensors the rule inspects.  <b>Optional</b>  Valid values: List of strings or a comma-separated string  Default value: None
<code>tensor_regex</code>	A list of regex patterns used to restrict this comparison to specific scalar-valued tensors. The rule inspects only the tensors that match the regex patterns specified in the list. If no patterns are passed, the rule compares all tensors gathered in the trials by default. Only scalar-valued tensors can be matched.  <b>Optional</b>  Valid values: List of strings or a comma-separated string  Default value: None
<code>max_threshold</code>	The threshold for the upper bound of tensor variance.  <b>Optional</b>  Valid values: Float  Default value: None
<code>min_threshold</code>	The threshold for the lower bound of tensor variance.  <b>Optional</b>  Valid values: Float  Default value: None

```
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.tensor_variance(),
        rule_parameters={
            "collection_names": "weights",

```

```

        "max_threshold": "10",
        "min_threshold": "0.00001",
    },
    collections_to_save=[
        CollectionConfig(
            name="weights",
            parameters={
                "save_interval": "500"
            }
        )
    ]
]

```

## UnchangedTensor

This rule detects whether a tensor is no longer changing across steps.

This rule runs the [numpy.allclose](#) method to check if the tensor isn't changing.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm. You must specify either the `collection_names` or `tensor_regex` parameter. If both the parameters are specified, the rule inspects the union of tensors from both sets.

For an example of how to configure and deploy a built-in rule, see [Configure Debugger Built-in Rules \(p. 1608\)](#).

### Parameter Descriptions for the UnchangedTensor Rule

Parameter Name	Description
<code>base_trial</code>	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.  <b>Required</b>  Valid values: String
<code>collection_names</code>	The list of collection names whose tensors the rule inspects.  <b>Optional</b>  Valid values: List of strings or a comma-separated string  Default value: None
<code>tensor_regex</code>	A list of regex patterns used to restrict this comparison to specific scalar-valued tensors. The rule inspects only the tensors that match the regex patterns specified in the list. If no patterns are passed, the rule compares all tensors gathered in the trials by default. Only scalar-valued tensors can be matched.  <b>Optional</b>

Parameter Name	Description
	<p>Valid values: List of strings or a comma-separated string</p> <p>Default value: None</p>
<code>num_steps</code>	<p>The number of steps across which the rule checks to determine if the tensor has changed.</p> <p>This checks the last <code>num_steps</code> that are available. They don't need to be consecutive. If <code>num_steps</code> is 2, at step s it doesn't necessarily check for s-1 and s. If s-1 isn't available, it checks the last available step along with s. In that case, it checks the last available step with the current step.</p> <p><b>Optional</b></p> <p>Valid values: Integer</p> <p>Default value: 3</p>
<code>rtol</code>	<p>The relative tolerance parameter to be passed to the <code>numpy.allclose</code> method.</p> <p><b>Optional</b></p> <p>Valid values: Float</p> <p>Default value: <code>1e-05</code></p>
<code>atol</code>	<p>The absolute tolerance parameter to be passed to the <code>numpy.allclose</code> method.</p> <p><b>Optional</b></p> <p>Valid values: Float</p> <p>Default value: <code>1e-08</code></p>
<code>equal_nan</code>	<p>Whether to compare NaNs as equal. If <code>True</code>, NaNs in input array a are considered equal to NaNs in input array b in the output array. This parameter is passed to the <code>numpy.allclose</code> method.</p> <p><b>Optional</b></p> <p>Valid values: Boolean</p> <p>Default value: <code>False</code></p>

```

built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.unchanged_tensor(),
        rule_parameters={
            "collection_names": "losses",
            "tensor_regex": "",
            "num_steps": "3",
            "rtol": "1e-05",
        }
    )
]

```

```

        "atol": "1e-08",
        "equal_nan": "False"
    },
    collections_to_save:[
        CollectionConfig(
            name="losses",
            parameters={
                "save_interval": "500"
            }
        )
    ]
]

```

## CheckInputImages

This rule checks if input images have been correctly normalized. Specifically, it detects if the mean of the sample data differs by more than a threshold value from zero. Many computer vision models require that input data has a zero mean and unit variance.

This rule is applicable to deep learning applications.

For an example of how to configure and deploy a built-in rule, see [Configure Debugger Built-in Rules \(p. 1608\)](#).

### Parameter Descriptions for the CheckInputImages Rule

Parameter Name	Description
base_trial	<p>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.</p> <p><b>Required</b></p> <p>Valid values: String</p>
threshold_mean	<p>A threshold that defines by how much mean of the input data can differ from 0.</p> <p><b>Optional</b></p> <p>Valid values: Float</p> <p>Default value: 0 . 2</p>
threshold_samples	<p>The number of images that have to be sampled before an error can be thrown. If the value is too low, the estimation of the dataset mean will be inaccurate.</p> <p><b>Optional</b></p> <p>Valid values: Integer</p> <p>Default value: 500</p>
regex	<p>The name of the input data tensor.</p> <p><b>Optional</b></p> <p>Valid values: String</p>

Parameter Name	Description
	<p>Default value: ".*hybridsequential0_input_0" (the name of the input tensor for Apache MXNet models using HybridSequential)</p>
channel	<p>The position of the color channel in the input tensor shape array.</p> <p><b>Optional</b></p> <p>Valid values: Integer</p> <p>Default value: 1 (for example, MXNet expects input data in the form of (batch_size, channel, height, width))</p>

```

built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.check_input_images(),
        rule_parameters={
            "threshold_mean": "0.2",
            "threshold_samples": "500",
            "regex": ".*/hybridsequential0_input_0",
            "channel": "1"
        },
        collections_to_save=[
            CollectionConfig(
                name="custom_inputs_collection",
                parameters={
                    "include_regex": ".*/hybridsequential0_input_0"
                    "save_interval": "500"
                }
            )
        ]
    )
]

```

## NLPSequenceRatio

This rule calculates the ratio of specific tokens given the rest of the input sequence that is useful for optimizing performance. For example, you can calculate the percentage of padding end-of-sentence (EOS) tokens in your input sequence. If the number of EOS tokens is too high, an alternate bucketing strategy should be performed. You also can calculate the percentage of unknown tokens in your input sequence. If the number of unknown words is too high, an alternate vocabulary could be used.

This rule is applicable to deep learning applications.

For an example of how to configure and deploy a built-in rule, see [Configure Debugger Built-in Rules \(p. 1608\)](#).

### Parameter Descriptions for the NLPSequenceRatio Rule

Parameter Name	Description
base_trial	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.

Parameter Name	Description
	<b>Required</b>  Valid values: String
<code>tensor_regex</code>	A list of regex patterns used to restrict this comparison to specific scalar-valued tensors. The rule inspects only the tensors that match the regex patterns specified in the list. If no patterns are passed, the rule compares all tensors gathered in the trials by default. Only scalar-valued tensors can be matched.  <b>Optional</b>  Valid values: List of strings or a comma-separated string  Default value: <code>".*embedding0_input_0"</code> (assuming an embedding as the initial layer of the network)
<code>token_values</code>	A string of a list of the numerical values of the tokens. For example, "3, 0".  <b>Optional</b>  Valid values: Comma-separated string of numerical values  Default value: 0
<code>token_thresholds_percent</code>	A string of a list of thresholds (in percentages) that correspond to each of the <code>token_values</code> . For example, "50.0, 50.0".  <b>Optional</b>  Valid values: Comma-separated string of floats  Default value: "50"

```

built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.nlp_sequence_ratio(),
        rule_parameters={
            "tensor_regex": ".*embedding0_input_0",
            "token_values": "0",
            "token_thresholds_percent": "50"
        },
        collections_to_save=[
            CollectionConfig(
                name="custom_inputs_collection",
                parameters={
                    "include_regex": ".*embedding0_input_0"
                }
            )
        ]
)

```

]

## Confusion

This rule evaluates the goodness of a confusion matrix for a classification problem.

It creates a matrix of size `category_no*category_no` and populates it with data coming from `(labels, predictions)` pairs. For each `(labels, predictions)` pair, the count in `confusion[labels][predictions]` is incremented by 1. When the matrix is fully populated, the ratio of data on-diagonal values and off-diagonal values are evaluated as follows:

- For elements on the diagonal: `confusion[i][i]/sum_j(confusion[j][j])>=min_diag`
- For elements off the diagonal: `confusion[j][i])/sum_j(confusion[j][i])<=max_off_diag`

This rule can be applied to the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see [Configure Debugger Built-in Rules \(p. 1608\)](#).

### Parameter Descriptions for the Confusion Rule

Parameter Name	Description
<code>base_trial</code>	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.  <b>Required</b>  Valid values: String
<code>category_no</code>	The number of categories.  <b>Optional</b>  Valid values: Integer $\geq 2$  Default value: "None"
<code>labels</code>	The <code>labels</code> tensor collection or an 1-d vector of true labels.  <b>Optional</b>  Valid values: String  Default value: "labels"
<code>predictions</code>	The <code>predictions</code> tensor collection or an 1-d vector of estimated labels.  <b>Optional</b>  Valid values: String  Default value: "predictions"
<code>labels_collection</code>	The rule inspects the tensors in this collection for labels.

Parameter Name	Description
	<b>Optional</b> Valid values: String Default value: "labels"
<code>predictions_collection</code>	The rule inspects the tensors in this collection for predictions. <b>Optional</b> Valid values: String Default value: "predictions"
<code>min_diag</code>	The minimum threshold for the ratio of data on the diagonal. <b>Optional</b> Valid values: <code>0≤float≤1</code> Default value: <code>0 . 9</code>
<code>max_off_diag</code>	The maximum threshold for the ratio of data off the diagonal. <b>Optional</b> Valid values: <code>0≤float≤1</code> Default value: <code>0 . 1</code>

```

built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.confusion(),
        rule_parameters={
            "category_no": "10",
            "labels": "labels",
            "predictions": "predictions",
            "labels_collection": "labels",
            "predictions_collection": "predictions",
            "min_diag": "0.9",
            "max_off_diag": "0.1"
        },
        collections_to_save=[
            CollectionConfig(
                name="labels",
                parameters={
                    "save_interval": "500"
                }
            ),
            CollectionConfig(
                name="predictions",
                parameters={
                    "include_regex": "500"
                }
            )
        ]
)

```

**Note**

This rule infers default values for the optional parameters if their values aren't specified.

## FeatureImportanceOverweight

This rule accumulates the weights of the *n* largest feature importance values per step and ensures that they do not exceed the threshold. For example, you can set the threshold for the top 3 features to not hold more than 80 percent of the total weights of the model.

This rule is valid only for the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see [Configure Debugger Built-in Rules \(p. 1608\)](#).

### Parameter Descriptions for the FeatureImportanceOverweight Rule

Parameter Name	Description
base_trial	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.  <b>Required</b>  Valid values: String
threshold	Defines the threshold for the proportion of the cumulative sum of the <i>n</i> largest features. The number <i>n</i> is defined by the nfeatures parameter.  <b>Optional</b>  Valid values: Float  Default value: 0 . 8
nfeatures	The number of largest features.  <b>Optional</b>  Valid values: Integer  Default value: 3
tensor_regex	Regular expression (regex) of tensor names the rule to analyze.  <b>Optional</b>  Valid values: String  Default value: ".*feature_importance/weight"

```
built_in_rules = [
```

```

Rule.sagemaker(
    base_config=rule_configs.feature_importance_overweight(),
    rule_parameters={
        "threshold": "0.8",
        "nfeatures": "3",
        "tensor_regex": ".*feature_importance/weight"
    },
    collections_to_save=[
        CollectionConfig(
            name="feature_importance",
            parameters={
                "save_interval": "500"
            }
        )
    ]
)
]

```

## TreeDepth

This rule measures the depth of trees in an XGBoost model. XGBoost rejects splits if they do not improve loss. This regularizes the training. As a result, the tree might not grow as deep as defined by the `depth` parameter.

This rule is valid only for the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see [Configure Debugger Built-in Rules \(p. 1608\)](#).

### Parameter Descriptions for the TreeDepth Rule

Parameter Name	Description
<code>base_trial</code>	The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.  <b>Required</b>  Valid values: String
<code>depth</code>	The depth of the tree. The depth of the tree is obtained by computing the base 2 logarithm of the largest node ID.  <b>Optional</b>  Valid values: Float  Default value: 4

```

built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.tree_depth(),
        rule_parameters={
            "depth": "4"
        },
        collections_to_save=[
            CollectionConfig(
                name="tree",

```

```
        parameters={
            "save_interval": "500"
        }
    ]
}
```

## Create Debugger Custom Rules for Training Job Analysis

You can create custom rules to monitor your training job using the Debugger Rule APIs and the open source [smdebug Python library](#) that provide tools to build your own rule containers.

### Topics

- [Prerequisites for Creating Debugger Custom Rules \(p. 1670\)](#)
- [Use the Debugger Client Library smdebug to Create a Custom Rule Python Script \(p. 1670\)](#)
- [Use the Debugger APIs to Run Your Own Custom Rules \(p. 1671\)](#)

## Prerequisites for Creating Debugger Custom Rules

To create Debugger custom rules, you need the following prerequisites.

- [SageMaker Debugger Rule.custom API](#)
- [The open source smdebug Python library](#)
- Your own custom rule python script
- [Amazon SageMaker Debugger Registry URLs for Custom Rule Evaluators \(p. 1739\)](#)

## Use the Debugger Client Library smdebug to Create a Custom Rule Python Script

The `smdebug` Rule API provides an interface to set up your own custom rules. The following python script is a sample of how to construct a custom rule, `CustomGradientRule`. This tutorial custom rule watches if the gradients are getting too large and set the default threshold as 10. The custom rule takes a base trial created by a SageMaker estimator when it initiates training job.

```
from smdebug.rules.rule import Rule

class CustomGradientRule(Rule):
    def __init__(self, base_trial, threshold=10.0):
        super().__init__(base_trial)
        self.threshold = float(threshold)

    def invoke_at_step(self, step):
        for tname in self.base_trial.tensor_names(collection="gradients"):
            t = self.base_trial.tensor(tname)
            abs_mean = t.reduction_value(step, "mean", abs=True)
            if abs_mean > self.threshold:
                return True
        return False
```

You can add multiple custom rule classes as many as you want in the same python script and deploy them to any training job trials by constructing custom rule objects in the following section.

## Use the Debugger APIs to Run Your Own Custom Rules

The following code sample shows how to configure a custom rule with the [Amazon SageMaker Python SDK](#). This example assumes that the custom rule script you created in the previous step is located at '`path/to/my_custom_rule.py`'.

```
from sagemaker.debugger import Rule, CollectionConfig

custom_rule = Rule.custom(
    name='MyCustomRule',
    image_uri='759209512951.dkr.ecr.us-west-2.amazonaws.com/sagemaker-debugger-rule-evaluator:latest',
    instance_type='ml.t3.medium',
    source='path/to/my_custom_rule.py',
    rule_to_invoke='CustomGradientRule',
    collections_to_save=[CollectionConfig("gradients")],
    rule_parameters={"threshold": "20.0"}
)
```

The following list explains the Debugger `Rule.custom` API arguments.

- `name` (str): Specify a custom rule name as you want.
- `image_uri` (str): This is the image of the container that has the logic of understanding your custom rule. It sources and evaluates the specified tensor collections you save in the training job. You can find the list of open source SageMaker rule evaluator images from [Amazon SageMaker Debugger Registry URLs for Custom Rule Evaluators \(p. 1739\)](#).
- `instance_type` (str): You need to specify an instance to build a rule docker container. This spins up the instance in parallel with a training container.
- `source` (str): This is the local path or the Amazon S3 URI to your custom rule script.
- `rule_to_invoke` (str): This specifies the particular Rule class implementation in your custom rule script. SageMaker supports only one rule to be evaluated at a time in a rule job.
- `collections_to_save` (str): This specifies which tensor collections you will save for the rule to run.
- `rule_parameters` (dictionary): This accepts parameter inputs in a dictionary format. You can adjust the parameters that you configured in the custom rule script.

After you set up the `custom_rule` object, you can use it for building a SageMaker estimator for any training jobs. Specify the `entry_point` to your training script. You do not need to make any change of your training script.

```
from sagemaker.tensorflow import TensorFlow

estimator = TensorFlow(
    role=sagemaker.get_execution_role(),
    base_job_name='smdebug-custom-rule-demo-tf-keras',
    entry_point='path/to/your_training_script.py'
    train_instance_type='ml.p2.xlarge'
    ...
    # debugger-specific arguments below
    rules = [custom_rule]
)

estimator.fit()
```

For more variations and advanced examples of using Debugger custom rules, see the following example notebooks.

- Monitor your training job with Amazon SageMaker Debugger custom rules
- PyTorch iterative model pruning of ResNet and AlexNet
- Trigger Amazon CloudWatch Events using Debugger Rules to Take an Action Based on Training Status with TensorFlow

## Use Debugger with Custom Training Containers

Amazon SageMaker Debugger is available for any deep learning models that you bring to Amazon SageMaker. The Amazon CLI, SageMaker Estimator API, and the Debugger APIs enable you to use any Docker base images to build and customize containers to train your models. To use Debugger with customized containers, you need to make a minimal change to your training script to implement the Debugger hook callback and retrieve tensors from training jobs.

You need the following resources to build a customized container with Debugger.

- [Amazon SageMaker Python SDK](#)
- [The SMDebug open source client library](#)
- A Docker base image of your choice
- Your training script with a Debugger hook registered – For more information about registering a Debugger hook to your training script, see [Register Debugger Hook to Your Training Script \(p. 1672\)](#).

For an end-to-end example of using Debugger with a custom training container, see the following example notebook.

- [Build a Custom Training Container and Debug Training Jobs with Debugger](#)

### Tip

This custom container with Debugger guide is an extension of the [Adapting Your Own Training Container \(p. 2151\)](#) guide which walks you thorough how to build and push your custom training container to Amazon ECR.

## Prepare to Build a Custom Training Container

To build a docker container, the basic structure of files should look like the following:

```
### debugger_custom_container_test_notebook.ipynb           # a notebook to run python snippet
codes
### debugger_custom_container_test_folder                  # this is a docker folder
    ### your-training-script.py                          # your training script with Debugger
hook
    ### Dockerfile                                     # a Dockerfile to build your own
container
```

## Register Debugger Hook to Your Training Script

To debug your model training, you need to add a Debugger hook to your training script.

### Note

This step is required to collect model parameters (output tensors) for debugging your model training. If you only want to monitor and profile, you can skip this hook registration step and exclude the `debugger_hook_config` parameter when constructing an estimator.

The following example code shows the structure of a training script using the Keras ResNet50 model and how to pass the Debugger hook as a Keras callback for debugging. To find a complete training script, see [TensorFlow training script with SageMaker Debugger hook](#).

```
# An example of training script (your-training-script.py)
import tensorflow.compat.v2 as tf
from tensorflow.keras.applications.resnet50 import ResNet50
import smdebug.tensorflow as smd

def train(batch_size, epoch, model, hook):

    ...
    model.fit(X_train, Y_train,
               batch_size=batch_size,
               epochs=epoch,
               validation_data=(X_valid, Y_valid),
               shuffle=True,

               # smdebug modification: Pass the Debugger hook in the main() as a Keras
               callback
               callbacks=[hook])

def main():
    parser=argparse.ArgumentParser(description="Train resnet50 cifar10")

    # hyperparameter settings
    parser.add_argument(...)

    args = parser.parse_args()

    model=ResNet50(weights=None, input_shape=(32,32,3), classes=10)

    # Add the following line to register the Debugger hook for Keras.
    hook=smd.KerasHook.create_from_json_file()

    # Start the training.
    train(args.batch_size, args.epoch, model, hook)

if __name__ == "__main__":
    main()
```

For more information about registering the Debugger hook for the supported frameworks and algorithm, see the following links in the SMDebug client library:

- [SMDebug TensorFlow hook](#)
- [SMDebug PyTorch hook](#)
- [SMDebug MXNet hook](#)
- [SMDebug XGBoost hook](#)

In the following example notebooks' training scripts, you can find more examples about how to add the Debugger hooks to training scripts and collect output tensors in detail:

- [Debugger in script mode with the TensorFlow 2.1 framework](#)

To see the difference between using Debugger in a Deep Learning Container and in script mode, open this notebook and put it and [the previous Debugger in a Deep Learning Container TensorFlow v2.1 notebook example](#) side by side.

In script mode, the hook configuration part is removed from the script in which you set the estimator. Instead, the Debugger hook feature is merged into the training script, [TensorFlow Keras ResNet training script in script mode](#). The training script imports the smdebug library in the required TensorFlow Keras environment to communicate with the TensorFlow ResNet50 algorithm. It also manually implements the smdebug hook functionality by adding the `callbacks=[hook]` argument

inside the `train` function (in line 49), and by adding the manual hook configuration (in line 89) provided through SageMaker Python SDK.

This script mode example runs the training job in the TF 2.1 framework for direct comparison with the zero script change in the TF 2.1 example. The benefit of setting up Debugger in script mode is the flexibility to choose framework versions not covered by Amazon Deep Learning Containers.

- [Using Amazon SageMaker Debugger in a PyTorch Container in Script Mode](#)

This notebook enables Debugger in script mode in PyTorch v1.3.1 framework. PyTorch v1.3.1 is supported by SageMaker containers, and this example shows details of how to modify a training script.

The SageMaker PyTorch estimator is already in script mode by default. In the notebook, the line to activate `script_mode` is not included in the estimator configuration.

This notebook shows detailed steps to change [an original PyTorch training script to a modified version with Debugger enabled](#). Additionally, this example shows how you can use Debugger built-in rules to detect training issues such as the vanishing gradients problem, and the Debugger trial features to call and analyze the saved tensors.

## Create and Configure a Dockerfile

Open your SageMaker JupyterLab and create a new folder, `debugger_custom_container_test_folder` in this example, to save your training script and Dockerfile. The following code example is a Dockerfile that includes essential docker build commands. Paste the following code into the Dockerfile text file and save it. Upload your training script to the same folder.

```
# Specify a docker base image
FROM tensorflow/tensorflow:2.2.0rc2-gpu-py3
RUN /usr/bin/python3 -m pip install --upgrade pip
RUN pip install --upgrade protobuf

# Install required packages to enable the SageMaker Python SDK and the smdebug library
RUN pip install sagemaker-training
RUN pip install smdebug
CMD ["bin/bash"]
```

If you want to use a pre-built Amazon Deep Learning Container image, see [Available Amazon Deep Learning Containers Images](#).

## Build and Push the Custom Training Container to Amazon ECR

Create a test notebook, `debugger_custom_container_test_notebook.ipynb`, and run the following code in the notebook cell. This will access the `debugger_byoc_test_docker` directory, build the docker with the specified `algorithm_name`, and push the docker container to your Amazon ECR.

```
import boto3

account_id = boto3.client('sts').get_caller_identity().get('Account')
ecr_repository = 'sagemaker-debugger-mnist-byoc-tf2'
tag = ':latest'

region = boto3.session.Session().region_name

uri_suffix = 'amazonaws.com'
if region in ['cn-north-1', 'cn-northwest-1']:
    uri_suffix = 'amazonaws.com.cn'
```

```
byoc_image_uri = '{}.dkr.ecr.{}/{}/{}'.format(account_id, region, uri_suffix,  
      ecr_repository + tag)  
  
!docker build -t $ecr_repository docker  
!$(aws ecr get-login --region $region --registry-ids $account_id --no-include-email)  
!aws ecr create-repository --repository-name $ecr_repository  
!docker tag {ecr_repository + tag} $byoc_image_uri  
!docker push $byoc_image_uri
```

**Tip**

If you use one of the Amazon Deep Learning Container base images, run the following code to log in to Amazon ECR and access to the Deep Learning Container image repository.

```
! aws ecr get-login-password --region {region} | docker login --username Amazon --  
password-stdin 763104351884.dkr.ecr.us-east-1.amazonaws.com
```

## Run and Debug Training Jobs Using the Custom Training Container

After you build and push your docker container to Amazon ECR, configure a SageMaker estimator with your training script and the Debugger-specific parameters. After you execute the `estimator.fit()`, Debugger will collect output tensors, monitor them, and detect training issues. Using the saved tensors, you can further analyze the training job by using the smdebug core features and tools. Configuring a workflow of Debugger rule monitoring process with Amazon CloudWatch Events and Amazon Lambda, you can automate a stopping training job process whenever the Debugger rules spots training issues.

```
import sagemaker  
from sagemaker.estimator import Estimator  
from sagemaker.debugger import Rule, DebuggerHookConfig, CollectionConfig, rule_configs  
  
profiler_config=ProfilerConfig(...)  
debugger_hook_config=DebuggerHookConfig(...)  
rules=[  
    Rule.sagemaker(rule_configs.built_in_rule()),  
    ProfilerRule.sagemaker(rule_configs.BuiltInRule())  
]  
  
estimator=Estimator(  
    image_uri=byoc_image_uri,  
    entry_point='./debugger_custom_container_test_folder/your-training-script.py'  
    role=sagemaker.get_execution_role(),  
    base_job_name='debugger-custom-container-test',  
    instance_count=1,  
    instance_type='ml.p3.2xlarge',  
  
    # Debugger-specific parameters  
    profiler_config=profiler_config,  
    debugger_hook_config=debugger_hook_config,  
    rules=rules  
)  
  
# start training  
estimator.fit()
```

## Action on Amazon SageMaker Debugger Rules

Based on the Debugger rule evaluation status, you can set up automated actions such as stopping a training job and sending notifications using Amazon Simple Notification Service (Amazon SNS). You can

also create your own actions using Amazon CloudWatch Events and Amazon Lambda. To learn how to set up automated actions based on the Debugger rule evaluation status, see the following topics.

#### Topics

- [Debugger Built-in Actions for Rules \(p. 1676\)](#)
- [Create Actions on Rules Using Amazon CloudWatch and Amazon Lambda \(p. 1680\)](#)

## Debugger Built-in Actions for Rules

Use Debugger built-in actions to respond to issues found by [Debugger Rule \(p. 1627\)](#). The `Debugger rule_configs` class provides tools to configure a list of actions, including automatically stopping training jobs and sending notifications using Amazon Simple Notification Service (Amazon SNS) when the Debugger rules find training issues.

### Step 1: Set Up Amazon SNS, Create an SMDebugRules Topic, and Subscribe to the Topic

This section walks you through how to set up an Amazon SNS `SMDebugRules` topic, subscribe to it, and confirm the subscription to receive notifications from the Debugger rules.

#### Note

For more information about billing for Amazon SNS, see [Amazon SNS pricing](#) and [Amazon SNS FAQs](#).

#### To create a SMDebugRules topic

1. Sign in to the Amazon Web Services Management Console and open the Amazon SNS console at <https://console.amazonaws.cn/sns/v3/home>.
2. In the left navigation pane, choose **Topics**.
3. On the **Topics** page, choose **Create topic**.
4. On the **Create topic** page, in the **Details** section, do the following:
  - a. For **Type**, choose **Standard** for topic type.
  - b. In **Name**, enter **SMDebugRules**.
5. Skip all other optional settings and choose **Create topic**. If you want to learn more about the optional settings, see [Creating an Amazon SNS topic](#).

#### To subscribe to the SMDebugRules topic

1. Open the Amazon SNS console at <https://console.amazonaws.cn/sns/v3/home>.
2. In the left navigation pane, choose **Subscriptions**.
3. On the **Subscriptions** page, choose **Create subscription**.
4. On the **Create subscription** page, in the **Details** section, do the following:
  - a. For **Topic ARN**, choose the **SMDebugRules** topic ARN. The ARN should be in format of `arn:aws:sns:<region-id>:111122223333:SMDebugRules`.
  - b. For **Protocol**, choose **Email** or **SMS**.
  - c. For **Endpoint**, enter the endpoint value, such as an email address or a phone number that you want to receive notifications.

#### Note

Make sure you type the correct email address and phone number. Phone numbers must include +, a country code, and phone number, with no special characters or spaces. For example, the phone number +1 (222) 333-4444 is formatted as **+12223334444**.

- Skip all other optional settings and choose **Create subscription**. If you want to learn more about the optional settings, see [Subscribing to an Amazon SNS topic](#).

After you subscribe to the **SMDebugRules** topic, you receive the following confirmation message in email or by phone:

For more information about Amazon SNS, see [Mobile text messaging \(SMS\)](#) and [Email notifications](#) in the [Amazon SNS Developer Guide](#).

## Step 2: Set Up Your IAM Role to Attach Required Policies

In this step, you add the required policies to your IAM role.

### To add the required policies to your IAM role

- Sign in to the Amazon Web Services Management Console and open the IAM console at <https://console.amazonaws.cn/iam/>.
- In the left navigation pane, choose **Policies**, and choose **Create policy**.
- On the **Create policy** page, do the following to create a new sns-access policy:
  - Choose the **JSON** tab.
  - Paste the JSON strings formatted in bold in the following code into the "Statement", replacing the 12-digit Amazon account ID with your Amazon account ID.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "VisualEditor0",  
            "Effect": "Allow",  
            "Action": [  
                "sns:Publish",  
                "sns:CreateTopic",  
                "sns:Subscribe"  
            ],  
            "Resource": "arn:aws:sns:*:111122223333:SMDebugRules"  
        }  
    ]  
}
```

- At the bottom of the page, choose **Review policy**.
  - On the **Review policy** page, for **Name**, enter **sns-access**.
  - At the bottom of the page, choose **Create policy**.
- Go back to the IAM console, and choose **Roles** in the left navigation pane.

5. Look up the IAM role that you use for SageMaker model training and choose that IAM role.
6. On the **Permissions** tab of the **Summary** page, choose **Attach policies**.
7. Search for the **sns-access** policy, select the check box next to the policy, and then choose **Attach policy**.

For more examples of setting up IAM policies for Amazon SNS, see [Example cases for Amazon SNS access control](#).

## Step 3: Configure Debugger Rules with the Built-in Actions

After successfully finishing the required settings in the preceding steps, you can configure the Debugger built-in actions for debugging rules as shown in the following example script. You can choose which built-in actions to use while building the `actions` list object. The `rule_configs` is a helper module that provides high-level tools to configure Debugger built-in rules and actions. The following built-in actions are available for Debugger:

- `rule_configs.StopTraining()` – Stops a training job when the Debugger rule finds an issue.
- `rule_configs.Email("abc@abc.com")` – Sends a notification via email when the Debugger rule finds an issue. Use the email address that you used when you set up your SNS topic subscription.
- `rule_configs.SMS("+1234567890")` – Sends a notification via text message when the Debugger rule finds an issue. Use the phone number that you used when you set up your SNS topic subscription.

### Note

Make sure you type the correct email address and phone number. Phone numbers must include +, a country code, and a phone number, with no special characters or spaces. For example, the phone number +1 (222) 333-4444 is formatted as **+12223334444**.

You can use all of the built-in actions or a subset of actions by wrapping up using the `rule_configs.ActionList()` method, which takes the built-in actions and configures a list of actions.

### To add all of the three built-in actions to a single rule

If you want to assign all of the three built-in actions to a single rule, configure a Debugger built-in action list while constructing an estimator. Use the following template to construct the estimator, and Debugger will stop training jobs and send notifications through email and text for any rules that you use to monitor your training job progress.

```
from sagemaker.debugger import Rule, rule_configs

# Configure an action list object for Debugger rules
actions = rule_configs.ActionList(
    rule_configs.StopTraining(),
    rule_configs.Email("abc@abc.com"),
    rule_configs.SMS("+1234567890")
)

# Configure rules for debugging with the actions parameter
rules = [
    Rule.sagemaker(
        base_config=rule_configs.built_in_rule(),           # Required
        rule_parameters={"paramter_key": "value"},          # Optional
        actions=actions
    )
]

estimator = Estimator(
    ...
)
```

```

        rules = rules
    )

estimator.fit(wait=False)

```

### To create multiple built-in action objects to assign different actions to a single rule

If you want to assign the built-in actions to be triggered at different threshold values of a single rule, you can create multiple built-in action objects as shown in the following script. To avoid a conflict error by running the same rule, you must submit different rule job names (specify different strings for the rules' name attribute) as shown in the following example script template. This example shows how to set up [StalledTrainingRule](#) (p. 1658) to take two different actions: send an email to abc@abc.com when a training job stalls for 60 seconds, and stop the training job if stalling for 120 seconds.

```

from sagemaker.debugger import Rule, rule_configs
import time

base_job_name_prefix= 'smdebug-stalled-demo-' + str(int(time.time()))

# Configure an action object for StopTraining
action_stop_training = rule_configs.ActionList(
    rule_configs.StopTraining()
)

# Configure an action object for Email
action_email = rule_configs.ActionList(
    rule_configs.Email("abc@abc.com")
)

# Configure a rule with the Email built-in action to trigger if a training job stalls for
# 60 seconds
stalled_training_job_rule_email = Rule.sagemaker(
    base_config=rule_configs.stalled_training_rule(),
    rule_parameters={
        "threshold": "60",
        "training_job_name_prefix": base_job_name_prefix
    },
    actions=action_email
)
stalled_training_job_rule_email.name="StalledTrainingJobRuleEmail"

# Configure a rule with the StopTraining built-in action to trigger if a training job
# stalls for 120 seconds
stalled_training_job_rule = Rule.sagemaker(
    base_config=rule_configs.stalled_training_rule(),
    rule_parameters={
        "threshold": "120",
        "training_job_name_prefix": base_job_name_prefix
    },
    actions=action_stop_training
)
stalled_training_job_rule.name="StalledTrainingJobRuleStopTraining"

estimator = Estimator(
    ...
    rules = [stalled_training_job_rule_email, stalled_training_job_rule]
)

estimator.fit(wait=False)

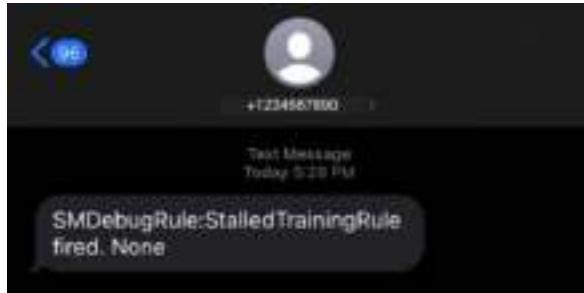

```

While the training job is running, the Debugger built-in action sends notification emails and text messages whenever the rule finds issues with your training job. The following screenshot shows an example of email notification for a training job that has a stalled training job issue.

## SMDebugRule:StalledTrainingRule fired

S SMDestroyRules <no-reply@sns.amazonaws.com> Today at 1:35 PM  
To:  
  
SMDebugRule:StalledTrainingRule fired. None  
  
If you wish to stop receiving notifications from this topic, please click or visit the link below to unsubscribe:  
<https://sns.us-east-1.amazonaws.com/unsubscribe.html?SubscriptionArn=arn:aws:sns:us-east-1:111122223333:SMDestroyRules:c6e0d93c-435a-4c43-084b-d98b4f12b19c&Endpoint>  
Please do not reply directly to this email. If you have any questions or comments regarding this email, please contact us at <https://aws.amazon.com/support>

The following screenshot shows an example text notification that Debugger sends when the rule finds a StalledTraining issue.

## Considerations for Using the Debugger Built-in Actions

- To use the Debugger built-in actions, an internet connection is required. This feature is not supported in the network isolation mode provided by Amazon SageMaker or Amazon VPC.
- The built-in actions cannot be used for [Debugger ProfilerRule \(p. 1626\)](#).
- The built-in actions cannot be used on training jobs with spot training interruptions.
- In email or text notifications, None appears at the end of messages. This does not have any meaning, so you can disregard the text None.

## Create Actions on Rules Using Amazon CloudWatch and Amazon Lambda

Amazon CloudWatch collects Amazon SageMaker model training job logs and Amazon SageMaker Debugger rule processing job logs. Configure Debugger with Amazon CloudWatch Events and Amazon Lambda to take action based on Debugger rule evaluation status.

### CloudWatch Logs for Debugger Rules and Training Jobs

#### To find training job logs and Debugger rule job logs

1. Open the CloudWatch console at <https://console.amazonaws.cn/cloudwatch/>.
2. In the left navigation pane under the **Log** node, choose **Log Groups**.
3. In the log groups list, do the following:
  - Choose **/aws/sagemaker/TrainingJobs** for training job logs.

- Choose **/aws/sagemaker/ProcessingJobs** for Debugger rule job logs.

You can use the training and Debugger rule job status in the CloudWatch logs to take further actions when there are training issues.

For more information about monitoring training jobs using CloudWatch, see [Monitor Amazon SageMaker](#).

## Set Up Debugger for Automated Training Job Termination Using CloudWatch and Lambda

The Debugger rules monitor training job status, and a CloudWatch Events rule watches the Debugger rule training job evaluation status.

### Step 1: Create a Lambda Function

#### To create a Lambda function

1. Open the Amazon Lambda console at <https://console.amazonaws.cn/lambda/>.
2. In the left navigation pane, choose **Functions** and then choose **Create function**.
3. On the **Create function** page, choose **Author from scratch** option.
4. In the **Basic information** section, enter a **Function name** (for example, **debugger-rule-stop-training-job**).
5. For **Runtime**, choose **Python 3.7**.
6. For **Permissions**, expand the drop down option, and choose **Change default execution role**.
7. For **Execution role**, choose **Use an existing role** and choose the IAM role that you use for training jobs on SageMaker.

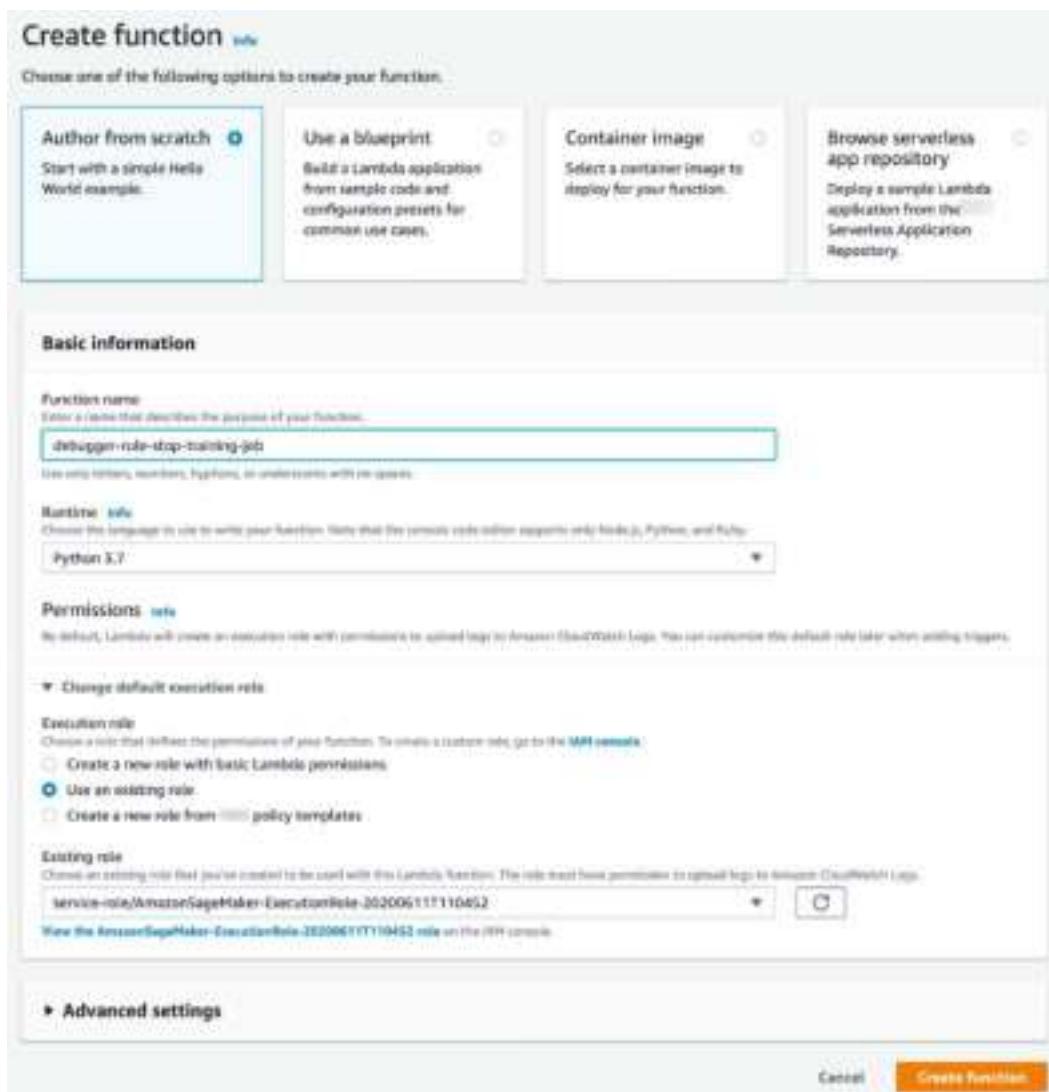

#### Note

Make sure you use the execution role with `AmazonSageMakerFullAccess` and `AWSLambdaBasicExecutionRole` attached. Otherwise, the Lambda function won't properly react to the Debugger rule status changes of the training job. If you are unsure which execution role is being used, run the following code in a Jupyter notebook cell to retrieve the execution role output:

```
import sagemaker
sagemaker.get_execution_role()
```

8. At the bottom of the page, choose **Create function**.

The following figure shows an example of the **Create function** page with the input fields and selections completed.

## Step 2: Configure the Lambda function

### To configure the Lambda function

1. In the **Function code** section of the configuration page, paste the following Python script in the Lambda code editor pane. The `lambda_handler` function monitors the Debugger rule evaluation status collected by CloudWatch and triggers the `StopTrainingJob` API operation. The Amazon SDK for Python (Boto3) client for SageMaker provides a high-level method, `stop_training_job`, which triggers the `StopTrainingJob` API operation.

```

import json
import boto3
import logging

logger = logging.getLogger()
logger.setLevel(logging.INFO)

def lambda_handler(event, context):
    training_job_name = event.get("detail").get("TrainingJobName")
    logging.info(f'Evaluating Debugger rules for training job: {training_job_name}')

```

```

eval_statuses = event.get("detail").get("DebugRuleEvaluationStatuses", None)

if eval_statuses is None or len(eval_statuses) == 0:
    logging.info("Couldn't find any debug rule statuses, skipping...")
    return {
        'statusCode': 200,
        'body': json.dumps('Nothing to do')
    }

# should only attempt stopping jobs with InProgress status
training_job_status = event.get("detail").get("TrainingJobStatus", None)
if training_job_status != 'InProgress':
    logging.debug(f"Current Training job status({training_job_status}) is not
'InProgress'. Exiting")
    return {
        'statusCode': 200,
        'body': json.dumps('Nothing to do')
    }

client = boto3.client('sagemaker')

for status in eval_statuses:
    logging.info(status.get("RuleEvaluationStatus") + ', RuleEvaluationStatus=' +
str(status))
    if status.get("RuleEvaluationStatus") == "IssuesFound":
        secondary_status = event.get("detail").get("SecondaryStatus", None)
        logging.info(
            f'About to stop training job, since evaluation of rule
configuration {status.get("RuleConfigurationName")}) resulted in "IssuesFound". ' +
            f'\ntraining job "{training_job_name}" status is
"{training_job_status}", secondary status is "{secondary_status}"' +
            f'\nAttempting to stop training job "{training_job_name}"'
        )
    )
try:
    client.stop_training_job(
        TrainingJobName=training_job_name
    )
except Exception as e:
    logging.error(
        "Encountered error while trying to "
        "stop training job {}: {}".format(
            training_job_name, str(e)
        )
    )
    raise e
return None

```

For more information about the Lambda code editor interface, see [Creating functions using the Amazon Lambda console editor](#).

2. Skip all other settings and choose **Save** at the top of the configuration page.

### Step 3: Create a CloudWatch Events Rule and Link to the Lambda Function for Debugger

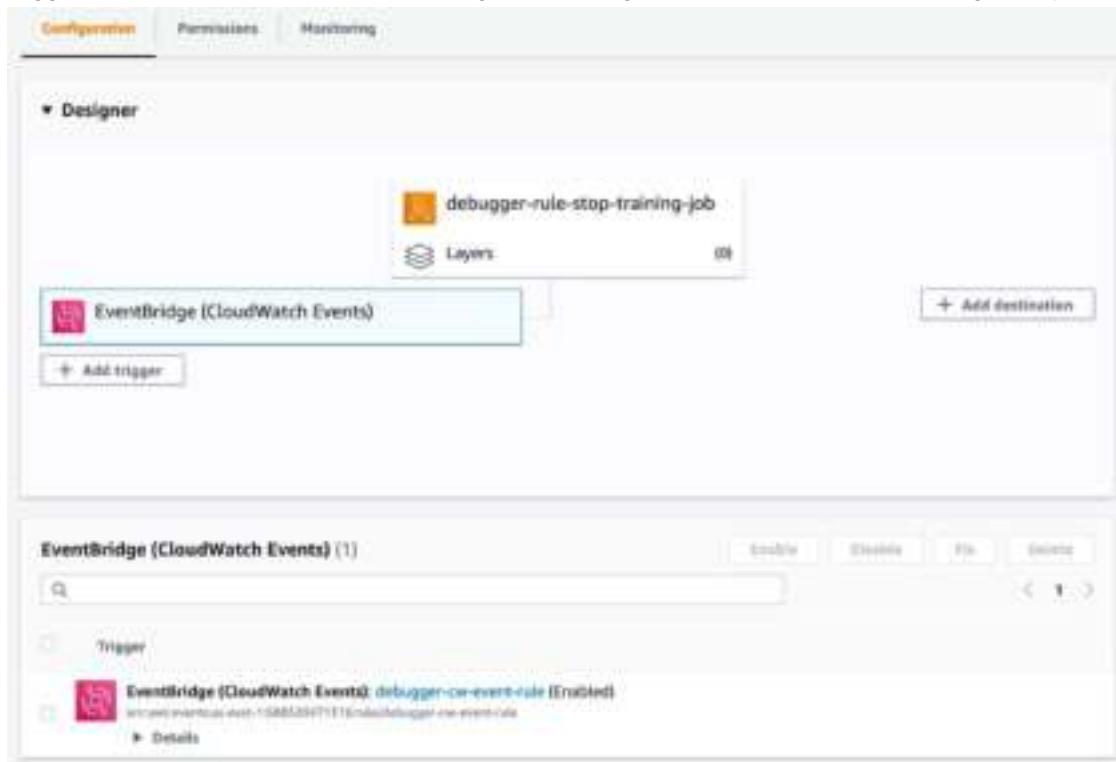

#### To create a CloudWatch Events rule and link to the Lambda function for Debugger

1. Open the CloudWatch console at <https://console.amazonaws.cn/cloudwatch/>.
2. In the left navigation pane, choose **Rules** under the **Events** node.
3. Choose **Create rule**.

4. In the **Event Source** section of the **Step 1: Create rule** page, choose **SageMaker** for **Service Name**, and choose **SageMaker Training Job State Change** for **Event Type**. The Event Pattern Preview should look like the following example JSON strings:

```
{  
    "source": [  
        "aws.sagemaker"  
    ],  
    "detail-type": [  
        "SageMaker Training Job State Change"  
    ]  
}
```

5. In the **Targets** section, choose **Add target\***, and choose the **debugger-rule-stop-training-job** Lambda function that you created. This step links the CloudWatch Events rule with the Lambda function.
6. Choose **Configure details** and go to the **Step 2: Configure rule details** page.
7. Specify the CloudWatch rule definition name. For example, **debugger-cw-event-rule**.
8. Choose **Create rule** to finish.
9. Go back to the Lambda function configuration page and refresh the page. Confirm that it's configured correctly in the **Designer** panel. The CloudWatch Events rule should be registered as a trigger for the Lambda function. The configuration design should look like the following example:

## Run Example Notebooks to Test Automated Training Job Termination

You can run the following example notebooks, which are prepared for experimenting with stopping a training job using Debugger's built-in rules.

- [Amazon SageMaker Debugger - Reacting to CloudWatch Events from Debugger rules](#)

This example notebook runs a training job that has a vanishing gradient issue. The Debugger [VanishingGradient \(p. 1646\)](#) built-in rule is used while constructing the SageMaker TensorFlow estimator. When the Debugger rule detects the issue, the training job is terminated.

- [Detect stalled training and stop training job using Debugger rule](#)

This example notebook runs a training script with a code line that forces it to sleep for 10 minutes. The Debugger [StalledTrainingRule \(p. 1658\)](#) built-in rule invokes issues and stops the training job.

## Disable the CloudWatch Events Rule to Stop Using the Automated Training Job Termination

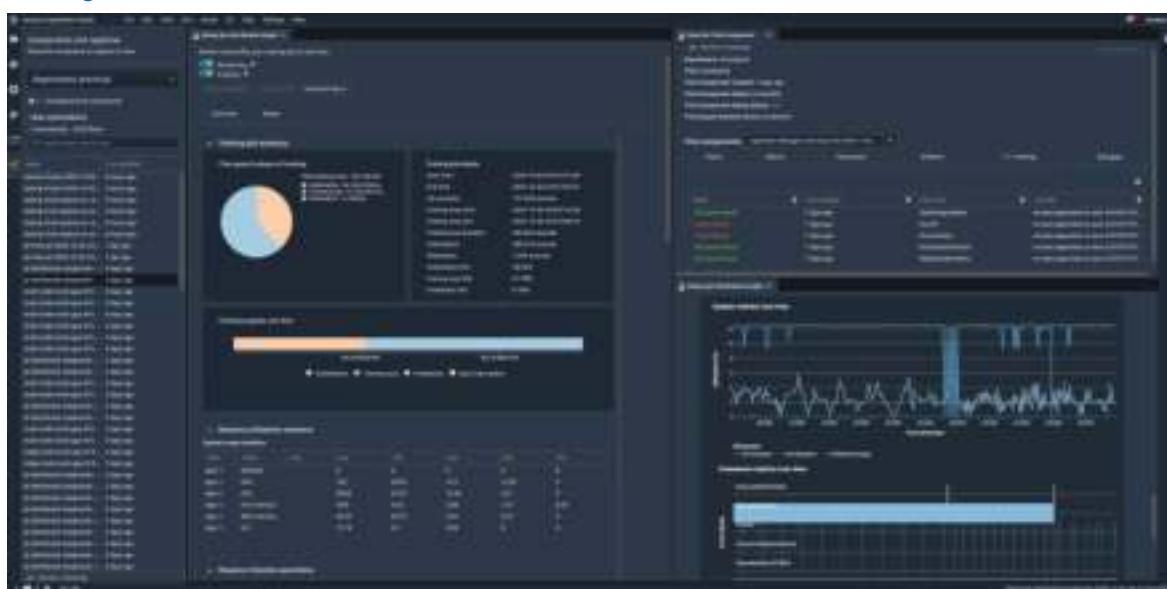

If you want to disable the automated training job termination, you need to disable the CloudWatch Events rule. In the Lambda **Designer** panel, choose the **EventBridge (CloudWatch Events)** block linked to the Lambda function. This shows an **EventBridge** panel below the **Designer** panel (for example, see the [previous screen shot](#)). Select the check box next to **EventBridge (CloudWatch Events): debugger-cw-event-rule**, and then choose **Disable**. If you want to use the automated termination functionality later, you can enable the CloudWatch Events rule again.

## SageMaker Debugger on Studio

Use Debugger dashboards on Studio to analyze your model performance and system bottlenecks while running training jobs on Amazon Elastic Compute Cloud instances. Gain insights into your training jobs and improve your model training performance and accuracy with the Debugger dashboards. By default, Debugger monitors system metrics (CPU, GPU, CPU and GPU memory, Network, and data I/O) every 500 milliseconds and basic output tensors (loss and accuracy) every 500 iterations for training jobs. You can also further customize Debugger configuration parameter values and adjust the saving intervals through the Studio UI or using the [Amazon SageMaker Python SDK](#).

### Important

If using existing SageMaker Studio apps, you need to restart them to use the new features. For instructions on how to restart and update your Studio environment, see [Update Amazon SageMaker Studio](#).

### Topics

- [Open Amazon SageMaker Debugger Insights Dashboard \(p. 1686\)](#)

- [SageMaker Debugger Insights Dashboard Controller \(p. 1687\)](#)
- [SageMaker Debugger Insights Dashboard Walkthrough \(p. 1691\)](#)
- [Shut Down the SageMaker Debugger Insights Instance \(p. 1697\)](#)
- [SageMaker Debugger on Studio Experiments \(p. 1698\)](#)

## Open Amazon SageMaker Debugger Insights Dashboard

Open the Debugger insights dashboard on Studio to see profiling progress and results of resource utilization and system bottlenecks of your training job running on EC2 instances.

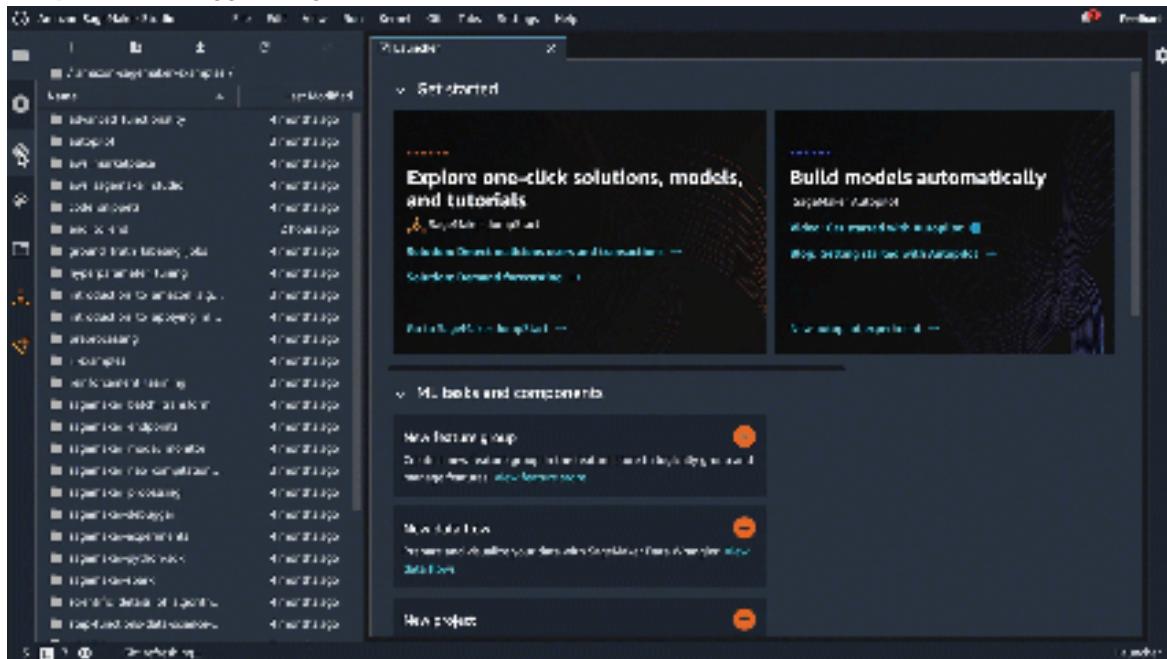

### Note

Studio Debugger insights dashboard runs a Studio app on an `m1.m5.4xlarge` instance to process and render the visualizations. Each Debugger insights tab runs one Studio kernel session. Multiple kernel sessions for multiple Debugger insights tabs run on the single instance. When you close a Debugger insights tab, the corresponding kernel session is also closed. A Studio app remains active and accrue charges for the `m1.m5.4xlarge` instance usage. For information about pricing, see the [Amazon SageMaker Pricing](#) page.

### Important

When you are done using the Debugger insights dashboard, you must shut down the `m1.m5.4xlarge` instance to avoid accruing charges. For instructions on how to shut down the instance, see [Shut Down the SageMaker Debugger Insights Instance \(p. 1697\)](#).

### To open the Debugger insights dashboard

1. Choose the **SageMakerComponents and registries** icon (💡).
2. Open the drop down menu, and choose **Experiments and trials**.
3. Look up your training job name. If you have not assigned a SageMaker Experiments trial component to the training job, the job is collected under the **Unassigned trial components** list.
4. **Right-click** (or an equivalent UI interaction) to open the context menu of the training job trial component. There are two menu items to access the Debugger features on Studio: **Open Debugger for insights** and **Open in trial details**.

5. Choose **Open Debugger for insights**. This opens a **Debug [your-training-job-name]** tab. In this tab, Debugger provides an overview of your model training performance on EC2 instances and identifies system bottleneck problems. While **monitoring** the system resource utilization, you can also enable **profiling** to capture framework metrics that consist of data from neural network operations executed during forward and backward pass and data loading. For more information about how to enable **profiling** using the Debugger insights dashboard controller, see [Enable and Configure Debugger Profiling for Detailed Insights \(p. 1688\)](#).

Debugger correlates the system resource utilization metrics with the framework metrics and helps identify resource-intensive operators that might be the root cause of the system bottlenecks. You can also download an aggregated Debugger profiling report. For more information, see [SageMaker Debugger Insights Dashboard Controller \(p. 1687\)](#).

## SageMaker Debugger Insights Dashboard Controller

There are different components of the Debugger Controller for monitoring and profiling. In this guide, you learn about the Debugger controller components.

### Note

Studio Debugger insights dashboard runs a Studio app on an `m1.m5.4xlarge` instance to process and render the visualizations. Each Debugger insights tab runs one Studio kernel session. Multiple kernel sessions for multiple Debugger insights tabs run on the single instance. When you close a Debugger insights tab, the corresponding kernel session is also closed. A Studio app remains active and accrue charges for the `m1.m5.4xlarge` instance usage. For information about pricing, see the [Amazon SageMaker Pricing](#) page.

### Important

When you are done using the Debugger insights dashboard, you must shut down the `m1.m5.4xlarge` instance to avoid accruing charges. For instructions on how to shut down the instance, see [Shut Down the SageMaker Debugger Insights Instance \(p. 1697\)](#).

## SageMaker Debugger Insights Controller UI

Using the Debugger controller located at the upper-left corner of the insights dashboard, you can refresh the dashboard, configure or update Debugger settings for monitoring system metrics and profiling framework metrics, stop training job, and download Debugger profiling report.

- If you want to manually refresh the **Debug [your-training-job-name]** page, choose the refresh button (the round arrow at the upper-left corner) as shown in the preceding screenshot.
- **Monitoring** is on by default for any SageMaker training job. By monitoring your training job, Debugger only collects system metrics to detect resource utilization problems, such as CPU bottlenecks and GPU underutilization. For a complete list of resource utilization problems that Debugger monitors, see [Debugger Built-in Rules for Monitoring Hardware System Resource Utilization \(System Metrics\) \(p. 1626\)](#).

- To download a comprehensive Debugger profiling report with details and analysis of a training job, choose **Download report**. For more information about the Debugger profiling report, see [SageMaker Debugger Profiling Report \(p. 1701\)](#).

## Enable and Configure Debugger Profiling for Detailed Insights

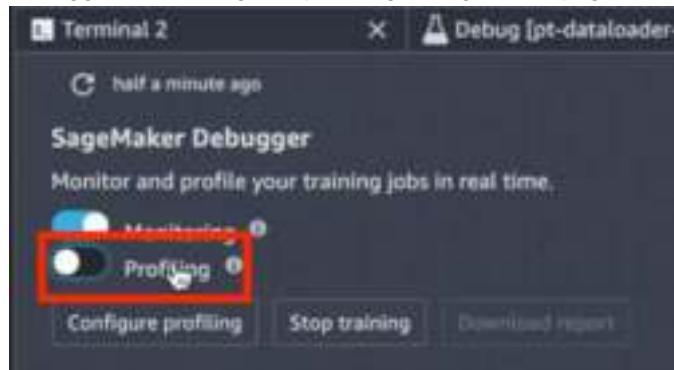

When you enable **Profiling**, Debugger starts collecting framework metrics. Framework metrics are model data collected from ML framework operations of your model, such as forward pass, backward pass, batch normalization, and data loader processes. Debugger correlates system performance bottlenecks with the framework operations and runs the [Debugger Built-in Rules for Profiling Framework Metrics \(p. 1626\)](#).

### Note

After you've enabled profiling, Debugger collects every framework operation call that's executed in each step: operations for convolving down input layers during forward pass, updating weights of millions of neurons during backward pass, and data loader processes. While profiling enables you to understand model performance at a deeper level, collecting framework metrics might impact your training time and performance. We recommend that you enable profiling to inspect your model up to two steps at a time. For more information about how to configure Debugger for framework profiling using [Amazon SageMaker Python SDK](#), see [Configure Debugger Framework Profiling \(p. 1598\)](#) and [Updating Debugger System Monitoring and Framework Profiling Configuration while a Training Job is Running \(p. 1602\)](#).

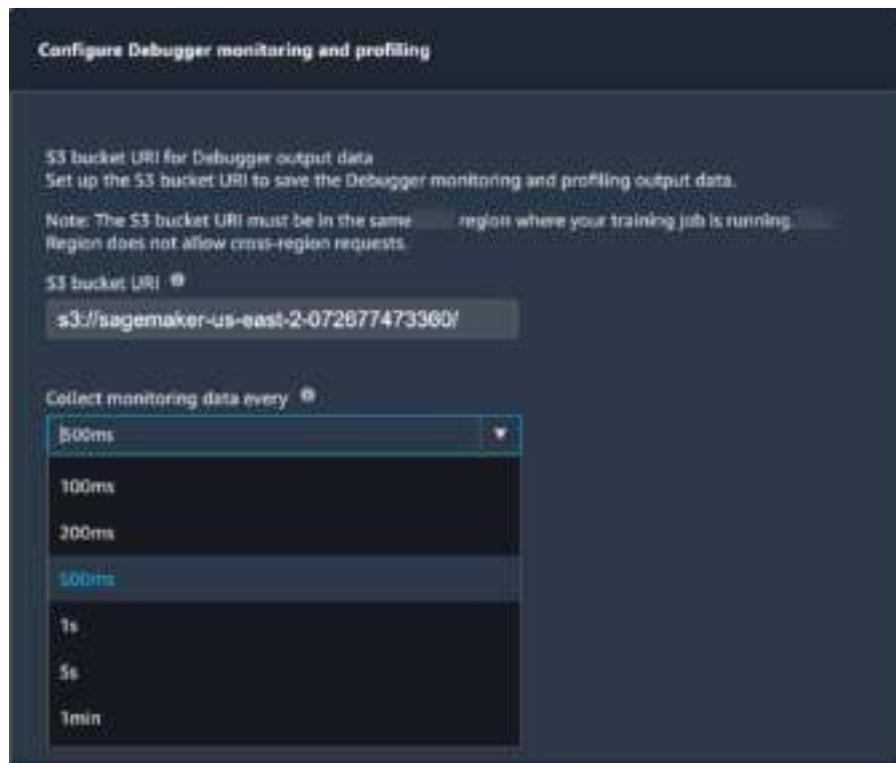

If you want to enable profiling while your training job is running, use the following steps to start profiling.

1. In SageMaker Studio, turn on **Profiling** to enable Debugger framework profiling. This opens a Debugger monitoring and profiling configuration page.

2. In **Configure Debugger monitoring and profiling**, **S3 bucket URI** and **Collect monitoring data every** are already set to the default values.

You can choose to change the monitoring interval using the drop down menu and selecting among the following available options: 100 milliseconds, 200 milliseconds, 500 milliseconds (default), 1 second, 5 seconds, and 1 minute.

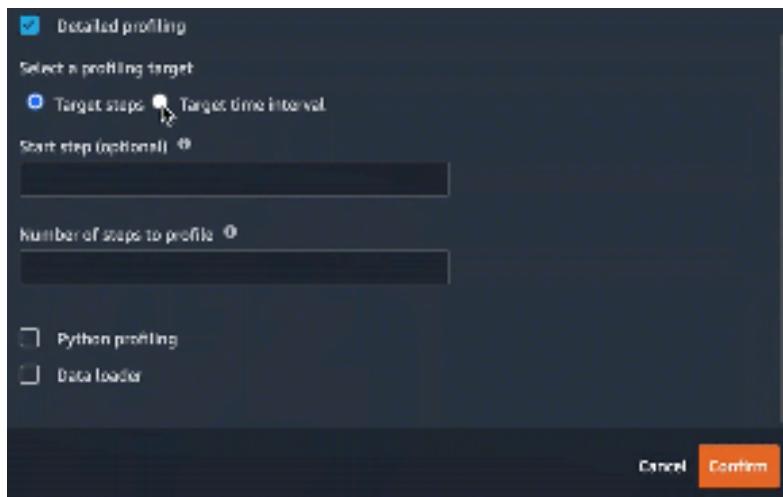

The following fields need to be specified:

- S3 bucket URI – Specify the base S3 bucket URI.
- Collect monitoring data every – Select a time interval to collect system metrics.

**Note**

If you choose one of the lower time intervals, you increase the granularity of monitoring system metrics. It allows you to capture spikes and anomalies with a higher time resolution. However, as the size of system metrics to process proportionally increases, it might impact the overall training and processing time.

3. In **Advanced settings for profiling**, configure framework metrics profiling options. Specify **Start step** (or **Start time**) and **Number of steps to profile** (or **Time duration to profile**) to profile. You can also leave the input fields blank. The default values will be automatically configured to use the current step and for 1 step duration.

- **Detailed profiling** – Specify a target step or time range to profile framework operations using the native framework profilers (TensorFlow profiler and PyTorch profiler). For example, if using TensorFlow, the Debugger hooks enable the TensorFlow profiler to collect TensorFlow-specific framework metrics. Detailed profiling enables you to profile all framework operators at a pre-step (before the first step), within steps, and between steps of a training job.

**Note**

The detailed profiling might significantly increase GPU memory consumption. It is not recommended to enable the detailed profiling for more than a couple of steps.

- **Python profiling** – Specify a target step or time range to profile Python functions. You can also choose between two Python profilers: cProfile and Pyinstrument.

- **cProfile** – The standard Python profiler. cProfile collects for every Python operator called during training. With cProfile, Debugger saves cumulative time and annotation of each function call, providing a complete detail of Python functions. In deep learning, for example, the most frequently called functions might be the convolutional filters and backward pass operators, and cProfile profiles every single of them. For the cProfile option, you can further select a timer option: total time, CPU time, and off-CPU time. While you can profile every function calls executing on processors (both CPU and GPU) in CPU time, you can also identify I/O or network bottlenecks with the off-CPU time option. The default is total time, and Debugger profiles both CPU and off-CPU time. With cProfile, you are able to drill down to every single functions when analyzing the profile data.
- **Pyinstrument** – Pyinstrument is a low overhead Python profiler that works based on sampling. With the Pyinstrument option, Debugger samples profiling events every millisecond. Because Pyinstrument measures elapsed wallclock time instead of CPU time, the Pyinstrument option can be a better choice over the cProfile option for reducing profiling noises (filtering out irrelevant function calls that are cumulatively fast) and capturing operators that are actually compute intensive (cumulatively slow) for training your model. With Pyinstrument, you are able to see a tree of function calls and better understand the structure and root cause of the slowness.

**Note**

Enabling Python profiling might result in slowing down the overall training time. In case of cProfile, Python operators that are the most frequently called are profiled at every call, so the processing time on profiling increases with respect to the number of calls. For Pyinstrument, the cumulative profiling time increases with respect to time because of its sampling mechanism.

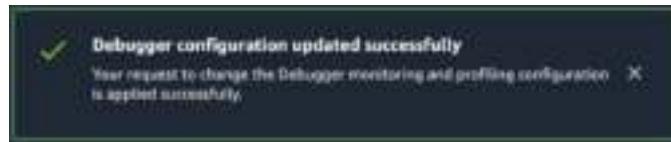

- **Dataloader profiling** – Specify a target step or time range to profile deep learning framework data loader processes. Debugger collects every data loader event of the frameworks.

**Note**

The data loader profiling can lower the training performance while collecting information from data loaders. We don't recommend that you enable the data loader profiling for more than a couple of steps.

Debugger is pre-configured to annotate data loader processes only for the Amazon deep learning containers. Debugger cannot profile data loader processes on any other custom or external containers.

4. Choose **Confirm** to finish your profiling configuration. When the configuration is successfully updated, you should be able to see the following confirmation message.

## SageMaker Debugger Insights Dashboard Walkthrough

When you initiate a SageMaker training job, Debugger starts monitoring hardware system resource utilization of EC2 instances by default. You can track the system utilization rate, statistics overview, and bottleneck detection status and results through the Studio. This guide walks you through every component of the Studio Debugger insights dashboard.

**Note**

Studio Debugger insights dashboard runs a Studio app on an `m1.m5.4xlarge` instance to process and render the visualizations. Each Debugger insights tab runs one Studio kernel session. Multiple kernel sessions for multiple Debugger insights tabs run on the single instance. When you close a Debugger insights tab, the corresponding kernel session is also closed. A Studio app remains active and accrue charges for the `m1.m5.4xlarge` instance usage. For information about pricing, see the [Amazon SageMaker Pricing](#) page.

**Important**

When you are done using the Debugger insights dashboard, you must shut down the `m1.m5.4xlarge` instance to avoid accruing charges. For instructions on how to shut down the instance, see [Shut Down the SageMaker Debugger Insights Instance \(p. 1697\)](#).

**Topics**

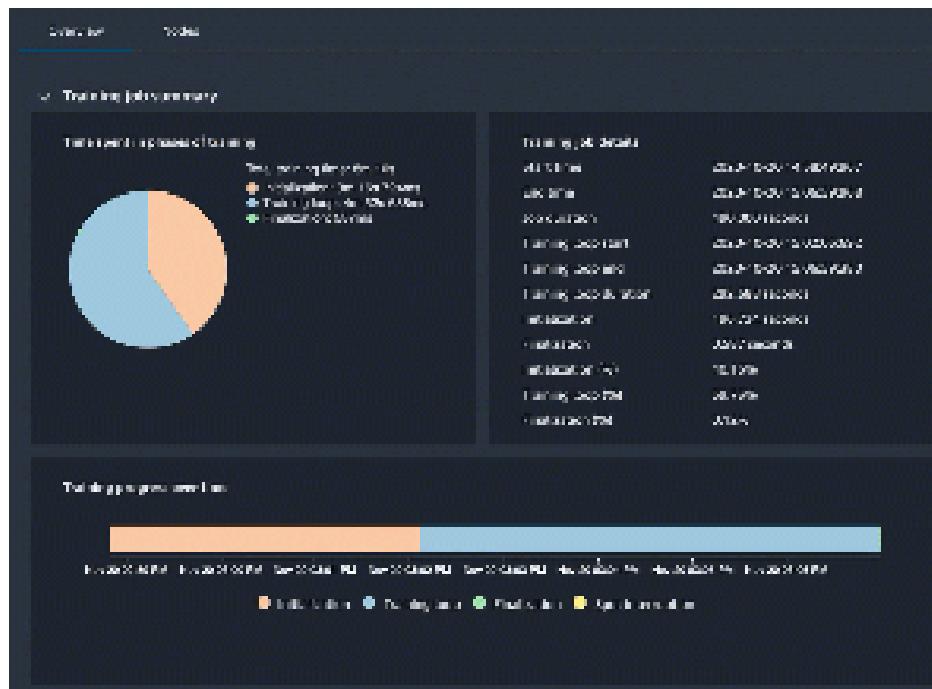

- [Debugger Insights – Overview \(p. 1691\)](#)
- [Debugger Insights – Nodes \(p. 1694\)](#)

### Debugger Insights – Overview

On the **Overview** tab, you can find a training job summary, resource utilization summary, resource intensive operations, and insights.

#### Training job summary

The **Training job summary** section shows the overall training time spent on different phases of training: initialization, training loop, and finalization. The pie chart shows the time usage percentage and absolute time amount spent on the different training phases. For example, you can have a high-level overview of how long it takes for initializing a training job, check if the initialization is taking too long due to data downloading, leaving the GPUs idle.

This section has the following features:

- The **Training progress over time** chart shows the timeline of the different training phase over time. If using spot training, you can also find the spot interruptions in the timeline chart.
- The **Training job details** panel shows the exact time stamps and utilization rate percentage numbers.
  - **Start time** – The exact time when the training job started.
  - **End time** – The exact time when the training job finished.
  - **Job duration** – The total training time from the **Start time** to the **End time**.
  - **Training loop start** – The exact time when the first step of the first epoch has started.
  - **Training loop end** – The exact time when the last step of the last epoch has finished.
  - **Training loop duration** – The total time between the Training loop start time and the Training loop end time.
  - **Initialization** – Time spent on initializing the training job, such as compiling the training script, initiating EC2 instances, and downloading training data.
  - **Finalization** – Time spent on finalizing the training job, such as finishing the model training, updating the model artifacts, and closing the EC2 instances.
  - **Initialization (%)** – The percentage of time spent on **Initialization** over the total **Job duration**.
  - **Training loop (%)** – The percentage of time spent on **Training loop** over the total **Job duration**.
  - **Finalization (%)** – The percentage of time spent on **Finalization** over the total **Job duration**.

### Resource utilization summary

This summary table shows hardware system resource utilization statistics of all workers (algo-n). System metrics include total CPU utilization, total GPU utilization, total CPU memory utilization, total GPU memory utilization, total I/O wait time, and total Network in bytes. The table shows the minimum and the maximum values, and p99, p90, and p50 percentiles.

Resource utilization summary							
System usage statistics							
Node	Name	CPU	Mem	GPU	Mem	GPU	Mem
sage-1	Network	344956425.3	0	0	0	0	0
sage-2	Network	0	0	0	0	0	0
sage-1	GPU	79	74.29	68.75	0	0	0
sage-2	GPU	75	74.25	66	0	0	0
sage-1	CPU	44.00	11.78	10.11	0	0	0
sage-2	CPU	37.5	11.87	10.43	0	0	0
sage-1	CPU memory	0.00	0.00	0.00	0.00	0.00	0.00
sage-2	CPU memory	0	0	0.00	0.00	0.00	0.00
sage-1	CPU memory	54.75	14.25	13.10	0	0	0
sage-2	CPU memory	67.75	11.75	14.5	0	0	0
sage-1	GPU	28.16	5.22	8.27	0	0	0
sage-2	GPU	23.00	4.25	9.02	0	0	0

## Resource intensive operations

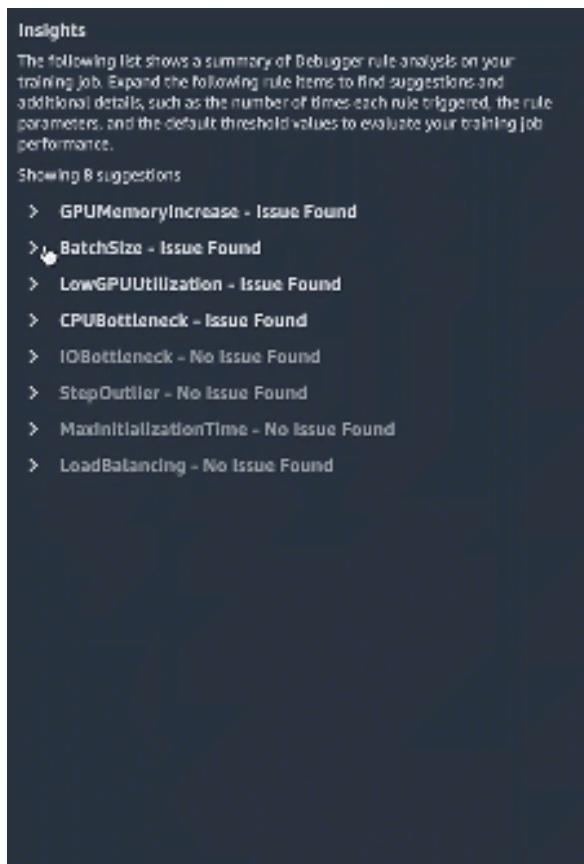

The **Resource intensive operations** section provides more detailed profiling results that show what operations of the training job were compute intensive. In the following example, it shows that the convolutional neural network backward pass operators were the most resource intensive on the GPUs.

Top operations on GPU		
Percentage (%)	Cumulative time	CPU operator
14.51	13805340	CudnnConvolutionBackward
34.48	13885079	subtot_convolution_backward
8.15	24028970	conv2d
6.11	24623438	convolution
6.08	2450894	_convolution
6.09	2421585	cuDNN_convolution
3.55	1351617	CudnnBatchNormBackward
3.31	1332746	custom_batch_norm_backward

## Insights

In the **Insights** pane, you can find training issues detected by Debugger built-in rules. You can expand each of the list to find useful insights, suggestions, a description of the rule, and criteria of triggering the rule.

For more information about the Debugger built-in rules, see [List of Debugger Built-in Rules \(p. 1626\)](#).

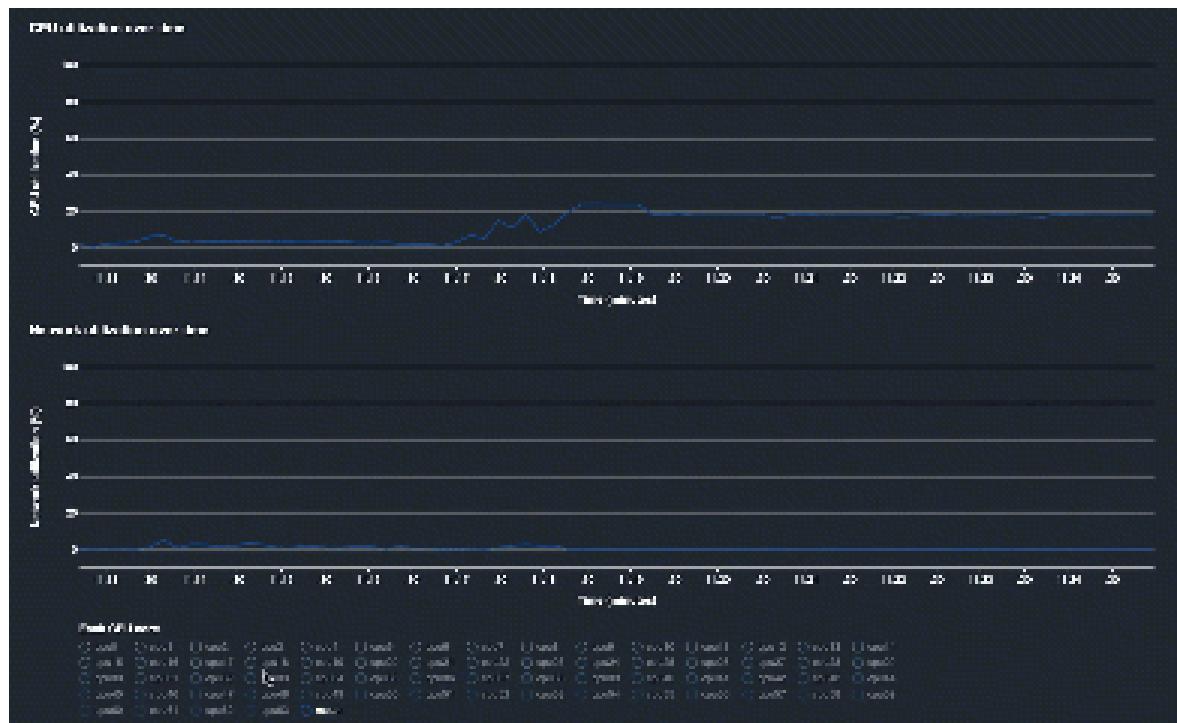

## Debugger Insights – Nodes

On the Studio Debugger Insight **Nodes** tab, Debugger provides detailed graphs that track each compute node on which your training jobs are running.

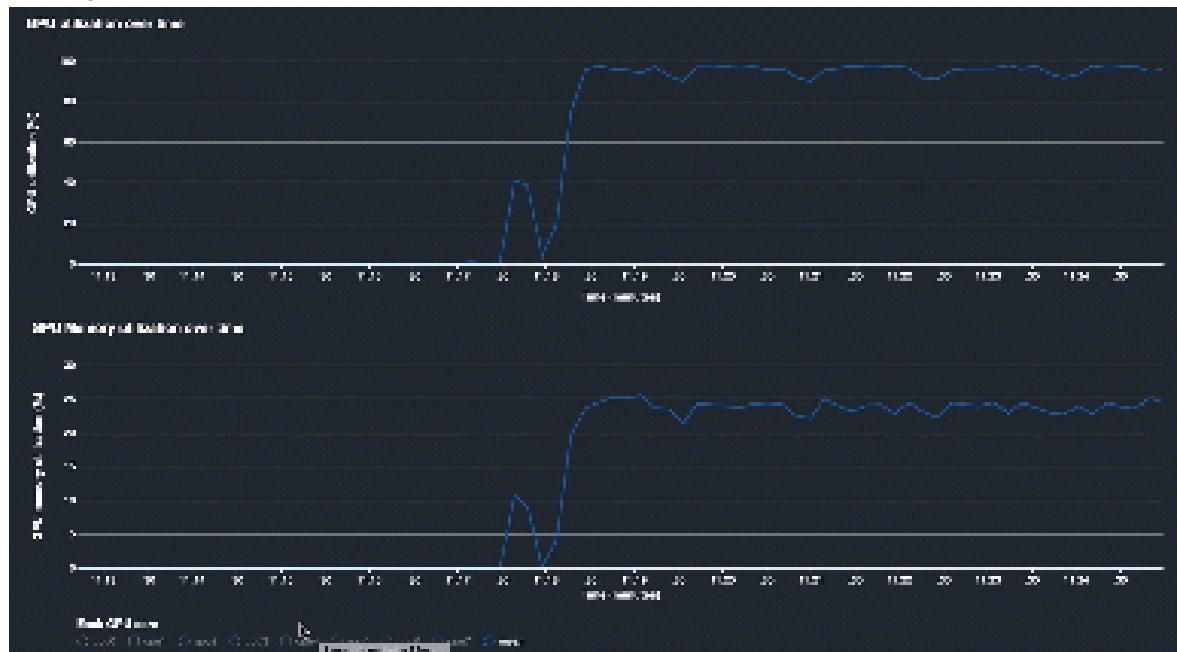

### CPU and Network utilization

The first two graphs show CPU utilization and network utilization over time. By default, the graphs show the mean values: the average of CPU and network utilization over the total number of CPU cores. You can select one or more CPU cores, by selecting on the labels, to graph them on single chart and compare utilization across cores. The timeline graphs are interactive, and the two graphs are synced up. You can drag and zoom in and out to see specific time windows that you want to have a closer look.

## GPU and GPU memory utilization

The following graphs show GPU utilization and GPU memory utilization over time. By default, the graphs show the mean utilization rate over time. You can select the GPU core labels to see the utilization rate of each core. Taking the mean of utilization rate over the total number of GPU cores shows the mean utilization of the entire hardware system resource. By looking at the mean utilization rate, you can check the overall system resource usage of EC2 instance. The following figure shows an example training job on an ml.p3.16xlarge instance with 8 GPU cores. You can monitor if the training job is well distributed, fully utilizing all GPUs.

### Overall system utilization over time

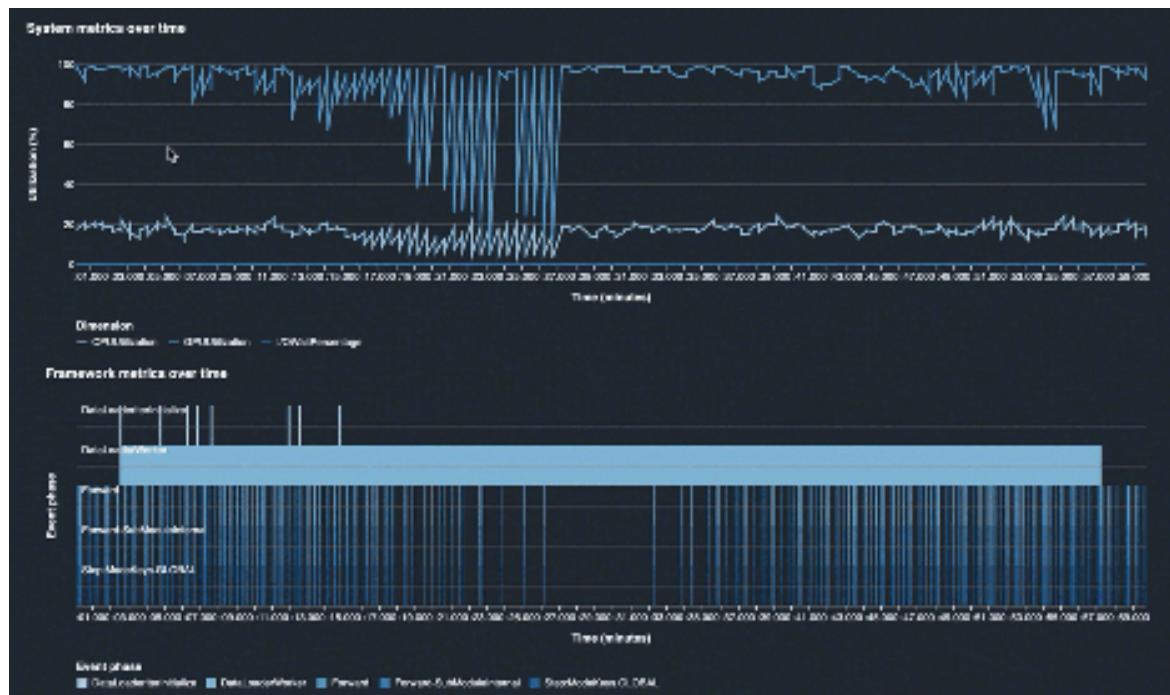

The following heatmap shows the entire system utilization over time projected onto the two-dimensional plot. Every CPU and GPU cores are listed in the vertical axis, and the utilization is recorded over time with colors. See the labeled colorbar on the right side of the plot to find out what color level corresponds to what utilization rate. For example, in the following heatmap, after initialization phase has ended around Sun 23:18, you can find that the training job fully utilizes an ml.p3.16xlarge instance; the GPU cores are fully utilized and the CPUs are moderately used for processing Python operations. There were several CPU bottleneck problems scattered across the CPUs at different times.

### System resource utilization over time and framework event phase

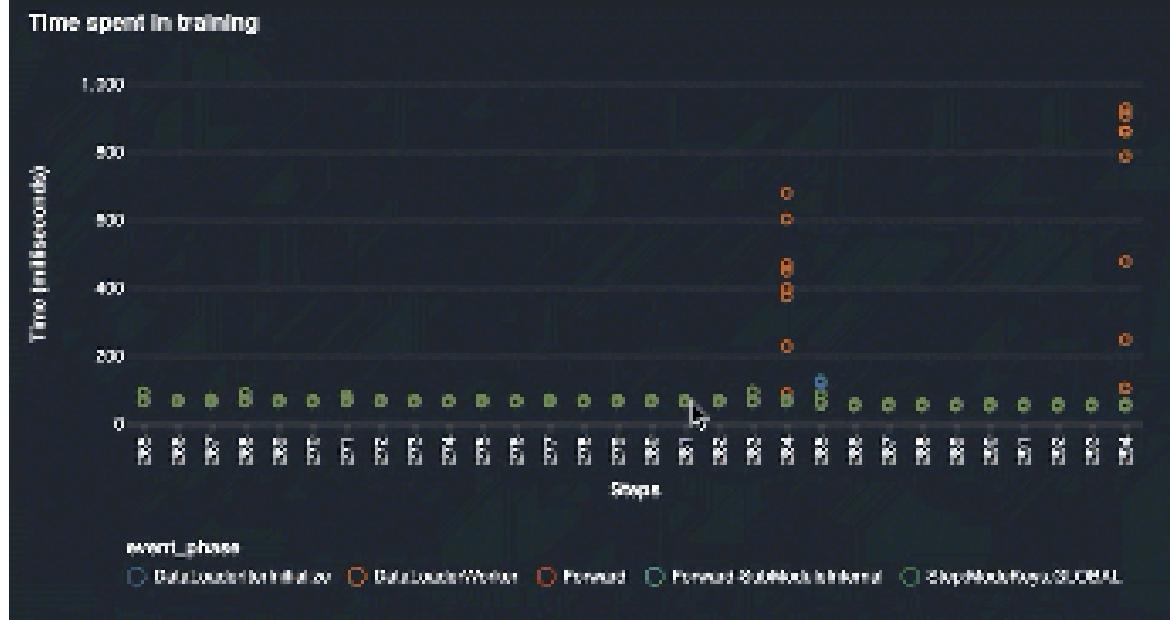

The **System metrics over time** graph shows the overall CPU, GPU, and data I/O utilization. The **Framework metrics over time** graph shows the framework metrics, which are the framework event phases that you can correlate with the **System metrics over time** graph.

You can select a time interval of interest in the system resource usage timeline, and the framework event phase spots the interval to show what events happened during the selected time interval. In each event phase block, you can find what time interval was actually spent for training loop, and break the training loop into backward pass and forward pass events. Overall, you can see that actual training time intervals are occupying only a small percentage over the entire training time.

### Time spent in training

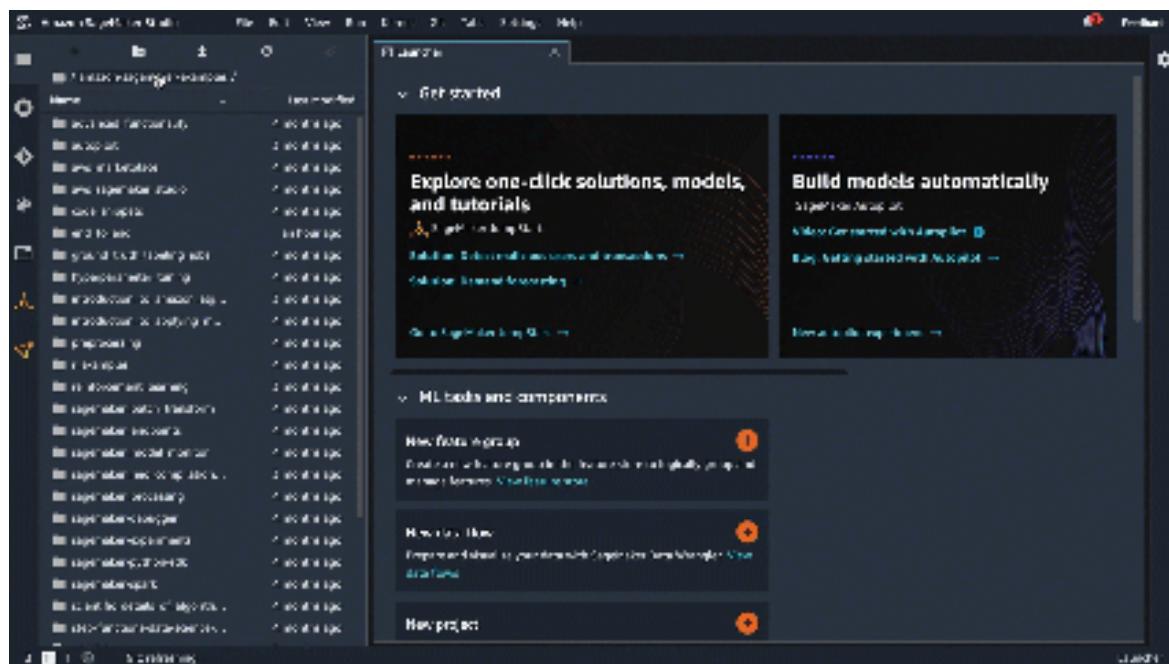

In the following graph, framework metrics from the last 30 steps of the last training loop are captured. This graph shows cumulative time spent by different events in each step.

## Shut Down the SageMaker Debugger Insights Instance

When you are not using the Debugger insights dashboard, it is important to shut down the instance on which it runs to avoid incurring additional fees.

### To shut down the Debugger insights instance in Studio

1. In Studio, select the **Running Instances and Kernels** icon ( ).
2. Under the **RUNNING APPS** list, look for the **sagemaker-debugger-1.0** app. Select the shut down icon ( ) next to the app. The Debugger insights dashboards run on an `m1.m5.4xlarge` instance. This instance also disappears from the **RUNNING INSTANCES** when you shut down the **sagemaker-debugger-1.0** app.

## SageMaker Debugger on Studio Experiments

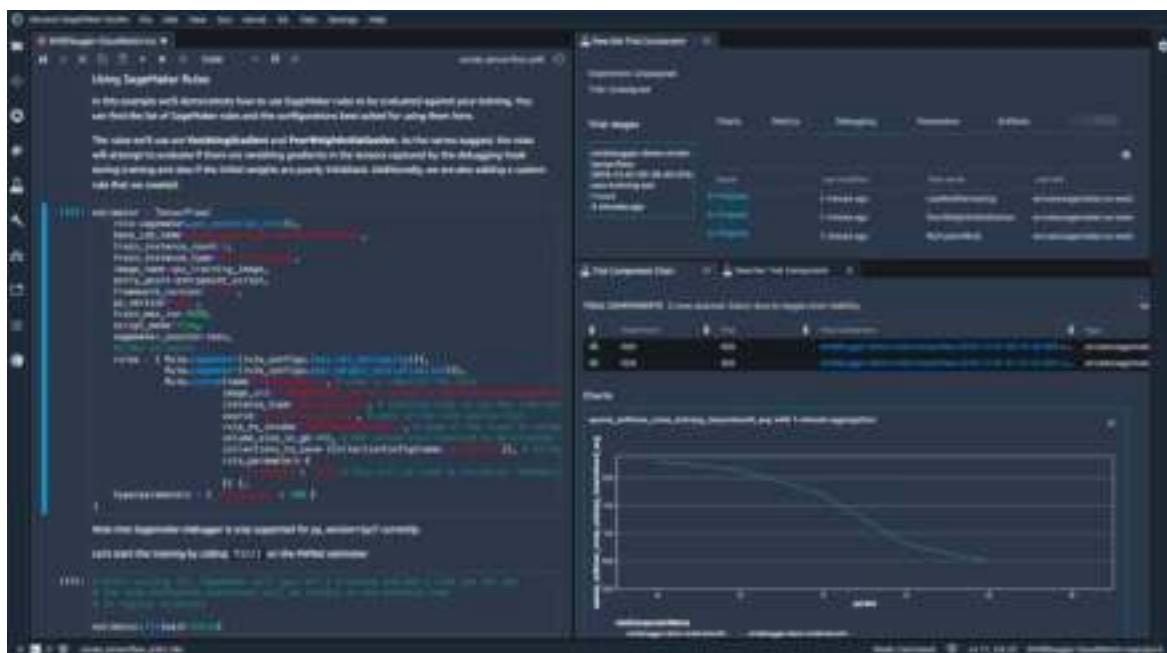

In this section, you learn how to use the Debugger in Studio Experiments. You can select any training jobs from the Experiment trial list to see the model output data graphs, such as accuracy and loss curves, debugging built-in rule status, and Debugger configuration information for debugging.

### Visualize Tensors Using SageMaker Debugger and Studio

SageMaker Studio provides visualizations to interpret tensor outputs that are captured by Debugger.

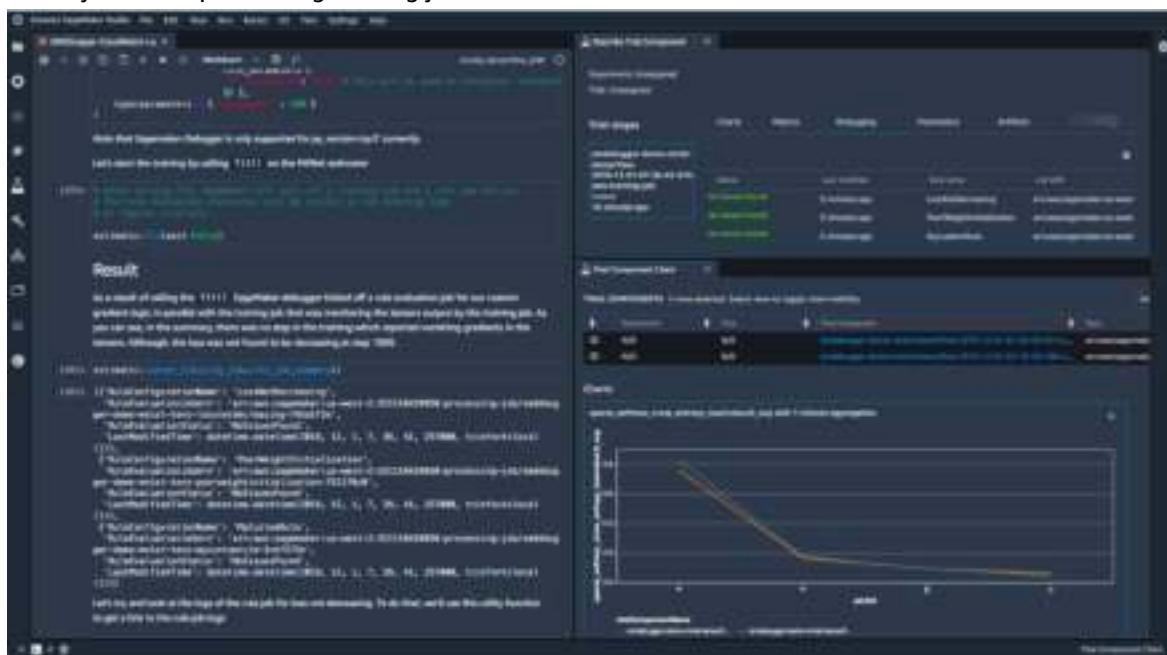

#### Loss Curves While Training Is in Progress

The following screenshot shows visualizations of loss curves for training. The training is in progress.

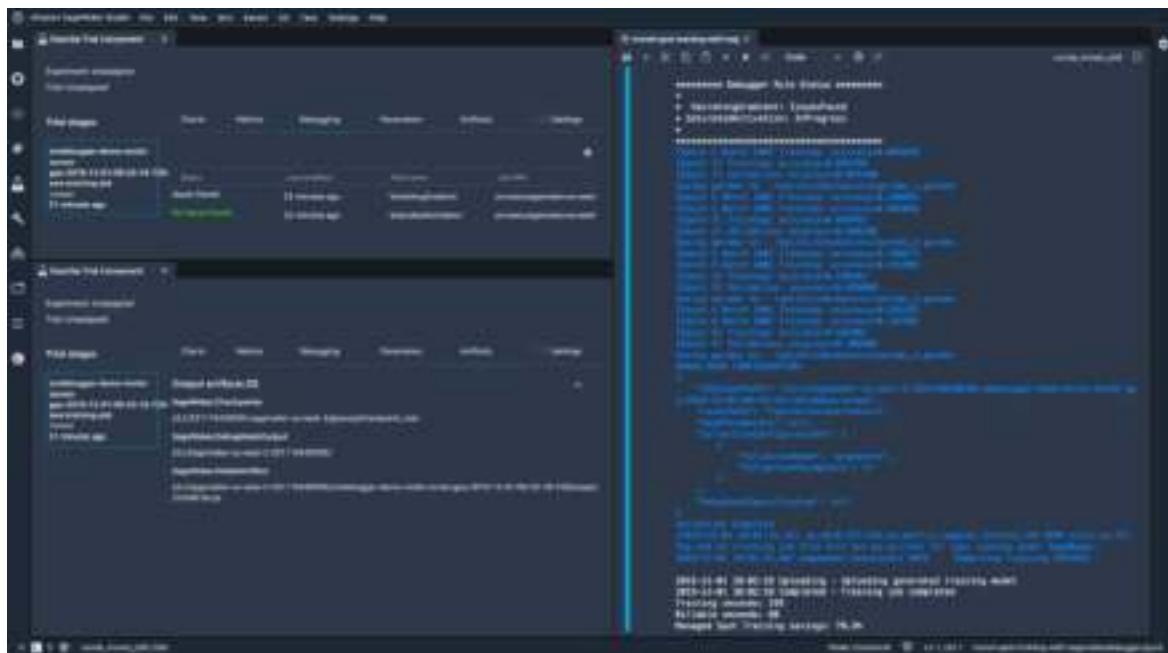

## Analyzing Training Jobs: Comparing Loss Curves Across Multiple Jobs

SageMaker Studio enables you to compare across multiple jobs (in this case, the loss). This helps you identify the best-performing training jobs.

## Rules Triggering and Logs from Jobs

When rules are triggered for anomalous conditions, SageMaker Studio presents logs for the failing rule. This enables you to analyze the causes of the condition.

## SageMaker Debugger Interactive Reports

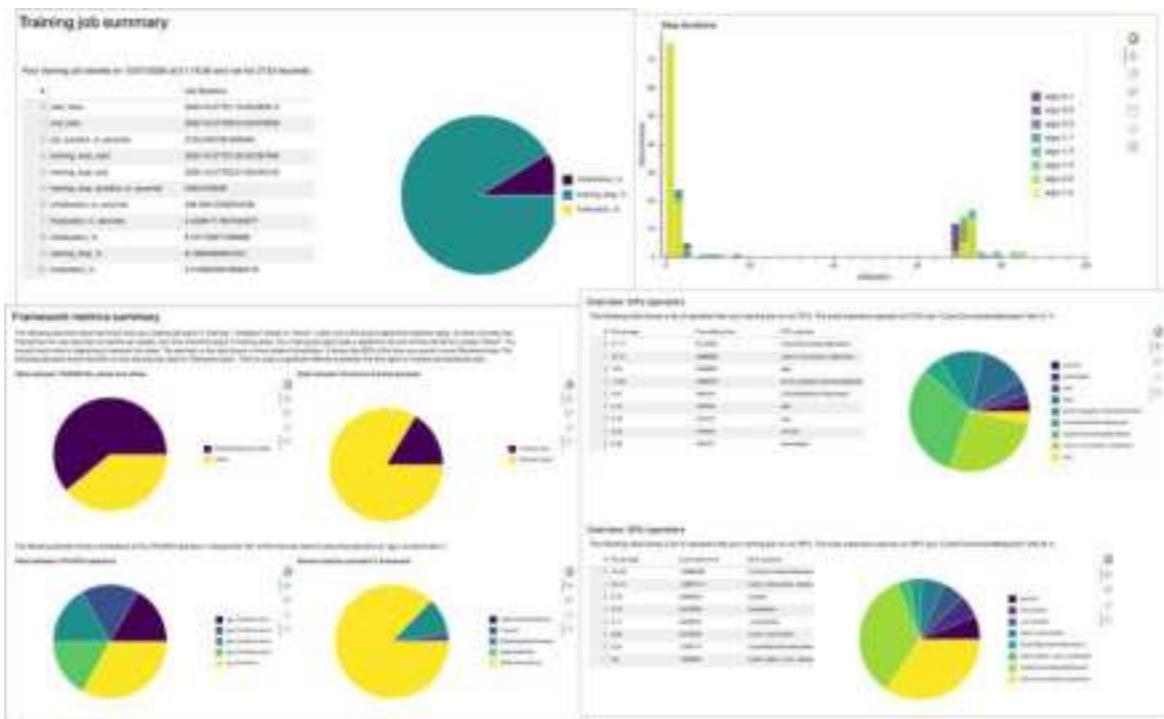

Receive training and profiling reports autogenerated by Debugger. The Debugger reports provide insights into your training jobs and suggest recommendations to improve your model performance. The following screenshot shows a collage of the Debugger profiling report. To learn more, see [SageMaker Debugger Profiling Report \(p. 1701\)](#).

### Note

You can download a Debugger reports while your training job is running or after the job has finished. During training, Debugger concurrently updates the report reflecting the current rules' evaluation status. You can download a complete Debugger report only after the training job has completed.

### Topics

- [SageMaker Debugger Profiling Report \(p. 1701\)](#)
- [SageMaker Debugger XGBoost Training Report \(p. 1711\)](#)

## SageMaker Debugger Profiling Report

For any SageMaker training jobs, the Debugger [ProfilerReport \(p. 1628\)](#) rule invokes all of the [monitoring and profiling rules \(p. 1626\)](#) and aggregates the rule analysis into a comprehensive report. Following this guide, download the report using the [Amazon SageMaker Python SDK](#) or the S3 console, and learn what you can interpret from the profiling results.

### Topics

- [Download a Debugger Profiling Report \(p. 1701\)](#)
- [Debugger Profiling Report Walkthrough \(p. 1704\)](#)

## Download a Debugger Profiling Report

Download the Debugger profiling report while your training job is running or after the job has finished using the [Amazon SageMaker Python SDK](#) and Amazon Command Line Interface (CLI).

### Tip

You can also download the report with one click and no additional scripting through the SageMaker Studio Debugger insights dashboard. To find out how to download the report from Studio, see [Open Amazon SageMaker Debugger Insights Dashboard \(p. 1686\)](#).

Download using SageMaker Python SDK and Amazon CLI

1. Check the current job's default S3 output base URI.

```
estimator.output_path
```

2. Check the current job name.

```
estimator.latest_training_job.job_name
```

- The Debugger profiling report is stored under <default-s3-output-base-uri>/<training-job-name>/rule-output. Configure the rule output path as follows:

```
rule_output_path = estimator.output_path + estimator.latest_training_job.job_name +
    "/rule-output"
```

- To check if the report is generated, list directories and files recursively under the rule\_output\_path using aws s3 ls with the --recursive option.

```
! aws s3 ls {rule_output_path} --recursive
```

This should return a complete list of files under an autogenerated folder that's named as ProfilerReport-1234567890. The folder name is a combination of strings: ProfilerReport and a unique 10-digit tag based on the Unix timestamp when the ProfilerReport rule is initiated.

The profiler-report.html is an autogenerated profiling report by Debugger. The remaining files are the built-in rule analysis components stored in JSON and a Jupyter notebook that are used to aggregate them into the report.

- Download the files recursively using aws s3 cp. The following command saves all of the rule output files to the ProfilerReport-1234567890 folder under the current working directory.

```
! aws s3 cp {rule_output_path} ./ --recursive
```

#### Tip

If using a Jupyter notebook server, run !pwd to double check the current working directory.

- Under the /ProfilerReport-1234567890/profiler-output directory, open profiler-report.html. If using JupyterLab, choose Trust HTML to see the autogenerated Debugger profiling report.

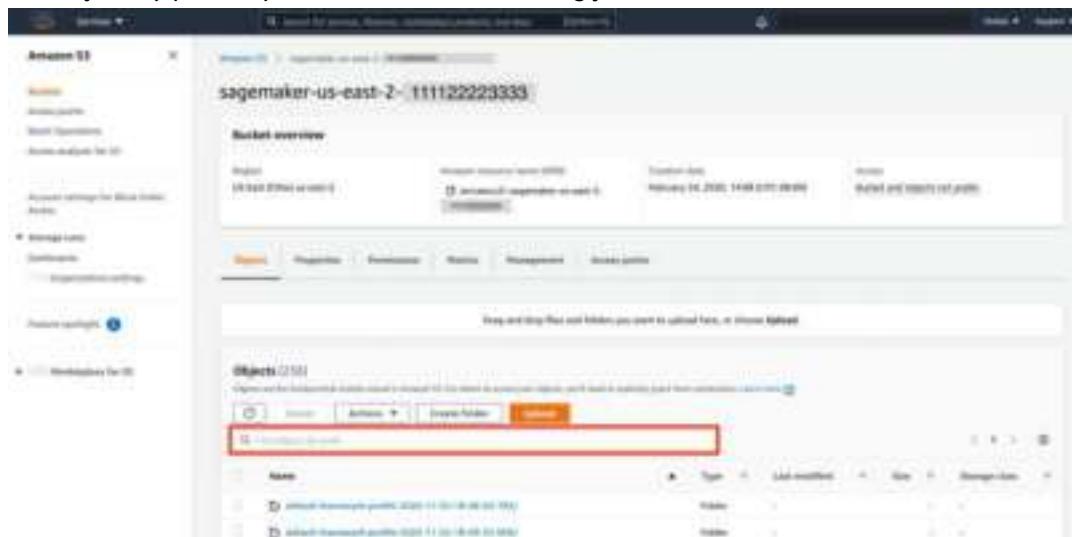

- Open the profiler-report.ipynb file to explore how the report is generated. You can also customize and extend the profiling report using the Jupyter notebook file.

#### Download using Amazon S3 Console

- Sign in to the Amazon Web Services Management Console and open the Amazon S3 console at <https://console.amazonaws.cn/s3/>.
- Search for the base S3 bucket. For example, if you haven't specified any base job name, the base S3 bucket name should be in the following format: sagemaker-<region>-111122223333. Look up the base S3 bucket through the *Find bucket by name* field.

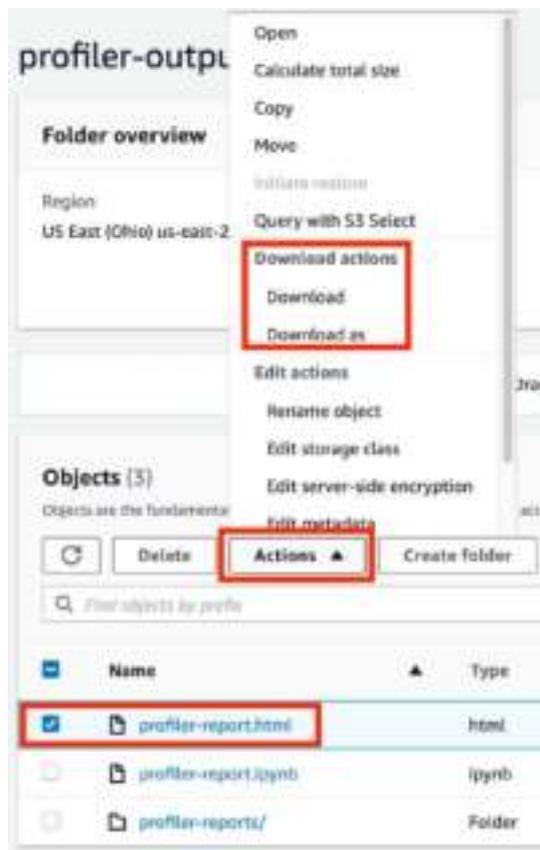

- In the base S3 bucket, look up the training job name by specifying your job name prefix into the *Find objects by prefix* input field. Choose the training job name.

- In the training job's S3 bucket, there must be three subfolders for training data collected by Debugger: **debug-output/**, **profiler-output/**, and **rule-output/**. Choose **rule-output/**.

- In the **rule-output/** folder, choose **ProfilerReport-1234567890**, and choose **profiler-output/** folder. The **profiler-output/** folder contains **profiler-report.html** (the autogenerated profiling report in html), **profiler-report.ipynb** (a Jupyter notebook with scripts that are used for generating the report), and a **profiler-report/** folder (contains rule analysis JSON files that are used as components of the report).
- Select the **profiler-report.html** file, choose **Actions**, and **Download**.

7. Open the downloaded **profiler-report.html** file in a web browser.

#### Note

If you started your training job without configuring the Debugger-specific parameters, Debugger generates the report based only on the system monitoring rules because the Debugger parameters are not configured to save framework metrics. To enable framework metrics profiling and receive an extended Debugger profiling report, configure the `profiler_config` parameter when constructing or updating SageMaker estimators.

To learn how to configure the `profiler_config` parameter before starting a training job, see [Configure Debugger Framework Profiling \(p. 1598\)](#).

To update the current training job and enable framework metrics profiling, see [Update Debugger Framework Profiling Configuration \(p. 1602\)](#).

## Debugger Profiling Report Walkthrough

This section walks you through the Debugger profiling report section by section. The profiling report is generated based on the built-in rules for monitoring and profiling. The report shows result plots only for the rules that found issues.

## Training Job Summary

At the beginning of the report, Debugger provides a summary of your training job. In this section, you can overview the time durations and timestamps at different training phases.

### Training job summary

The following table gives a summary about the training job. The table includes information about when the training job started and ended, how much time initialization, training loop and finalization took. Your training job started on 11/29/2020 at 23:12:42, and ran for 737 seconds.

#	Job Statistic
0	Start time
1	23:12:42 11/29/2020
2	End time
3	23:54:59 11/29/2020
4	Job duration
5	737 seconds
6	Training loop start
7	23:17:31 11/29/2020
8	Training loop end
9	23:24:59 11/29/2020
10	Training loop duration
11	115 seconds
12	Initialization time
13	285 seconds
14	Finalization time
15	0 seconds
16	Initialization
17	39 %
18	Training loop
19	60 %
20	Finalization
21	0 %

The summary table contains the following information:

- **start\_time** – The exact time when the training job started.
- **end\_time** – The exact time when the training job finished.
- **job\_duration\_in\_seconds** – The total training time from the **start\_time** to the **end\_time**.
- **training\_loop\_start** – The exact time when the first step of the first epoch has started.
- **training\_loop\_end** – The exact time when the last step of the last epoch has finished.
- **training\_loop\_duration\_in\_seconds** – The total time between the training loop start time and the training loop end time.
- **initialization\_in\_seconds** – Time spent on initializing the training job. The initialization phase covers the period from the **start\_time** to the **training\_loop\_start** time. The initialization time is spent on compiling the training script, starting the training script, creating and initializing the model, initiating EC2 instances, and downloading training data.
- **finalization\_in\_seconds** – Time spent on finalizing the training job, such as finishing the model training, updating the model artifacts, and closing the EC2 instances. The finalization phase covers the period from the **training\_loop\_end** time to the **end\_time**.
- **initialization (%)** – The percentage of time spent on **initialization** over the total **job\_duration\_in\_seconds**.
- **training loop (%)** – The percentage of time spent on **training loop** over the total **job\_duration\_in\_seconds**.
- **finalization (%)** – The percentage of time spent on **finalization** over the total **job\_duration\_in\_seconds**.

## System Usage Statistics

In this section, you can see an overview of system utilization statistics.

### System usage statistics

The 95th percentile of the total GPU utilization on node algo-2 is 74%. GPUs on node algo-2 are well utilized.

The following table shows usage statistics per worker node such as total CPU and GPU utilization, total CPU and memory footprint. The table also includes total I/O wait time and total sent/received bytes. The table shows min and max values as well as p99, p90 and p50 percentiles.

#	node -	metric	unit	max	p99	p90	p50	min
0	algo-1	Network	bytes	218817581.57	188.02	0	0	0
1	algo-1	I/O	percentage	13.2669129	8.862831250000000	0.1955937499999999	0	0
2	algo-1	CPU memory	percentage	30.25	26.25	21	0	0
3	algo-1	GPU	percentage	78	74.8	74.25	0	0
4	algo-1	CPU memory	percentage	8.06	6.04	4.98	2.17	0.33
5	algo-1	CPU	percentage	32.068828	22.62913125000000	17.034	3.703420000000000	0
6	algo-2	Network	bytes	4135.24	0	0	0	0
7	algo-2	I/O	percentage	29.1675	8.158290000000000	1.747613499999999	0	0
8	algo-2	CPU memory	percentage	38	31.75	21.75	0	0
9	algo-2	GPU	percentage	78	74.8	74.25	0	0
10	algo-2	CPU memory	percentage	8.06	6.04	4.99	2.17	0.39
11	algo-2	CPU	percentage	36.04370499999999	25.89998710000000	18.034298675	3.77829125	0

The Debugger profiling report includes the following information:

- **node** – Lists the name of nodes. If using distributed training on multiple nodes (multiple EC2 instances), the node names are in format of algo-n.
- **metric** – The system metrics collected by Debugger: CPU, GPU, CPU memory, GPU memory, I/O, and Network metrics.
- **unit** – The unit of the system metrics.
- **max** – The maximum value of each system metric.
- **p99** – The 99th percentile of each system utilization.
- **p90** – The 95th percentile of each system utilization.
- **p50** – The 50th percentile (median) of each system utilization.
- **min** – The minimum value of each system metric.

### Framework metrics summary

In this section, the following pie charts show the breakdown of framework operations on CPUs and GPUs.

### Framework metrics summary

This section provides an overview of the training job metrics. Within the type of training jobs, all the time recorded by the framework is either spent on the forward pass or backward pass. Detailed metrics should be used for further analysis. For training jobs specifically in a configuration of three DGX-2H GPU nodes, the following chart is reporting in seconds on the loops. The picture on the right shows a more detailed breakdown, showing that one of the time was spent in inverse Cholesky pass. The following sections show details about training and validation passes.

Ratio between TRAIN/EVAL phase and others

Ratio between forward and backward pass

The following figure shows the breakdown of CPU/GPU operators. It is worth 10% of the time recorded by the framework on Train/Eval loop.

Ratio between CPU/GPU operators

General metrics recorded in framework

Each of the pie charts analyzes the collected framework metrics in various aspects as follows:

- **Ratio between TRAIN/EVAL phase and others** – Shows the ratio between time durations spent on different training phases.
- **Ratio between forward and backward pass** – Shows the ratio between time durations spent on forward and backward pass in the training loop.
- **Ratio between CPU/GPU operators** – Shows the ratio between time spent on operators running on CPU or GPU, such as convolutional operators.
- **General metrics recorded in framework** – Shows the ratio between time spent on major framework metrics, such as data loading, forward and backward pass.

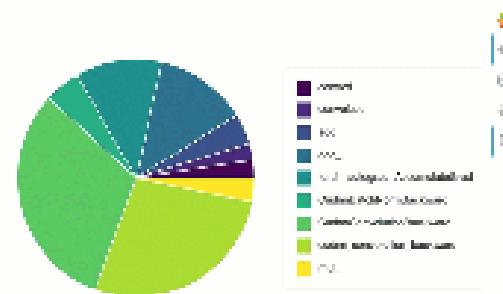

### Overview: CPU Operators

This section provides information of the CPU operators in detail. The table shows the percentage of the time and the absolute cumulative time spent on the most frequently called CPU operators.

## Overview: CPU operations

<sup>10</sup> The 1970 census showed 1,100,000 of the total 2000 population of 27,000,000 as being foreign-born.

#	Barcode ID	Current Status	CF Status
1	12345	On Hold	Queued for Review
2	56789	Completed	Completed
3	33333	... ...	...
4	44444	... ...	...
5	55555	... ...	...
6	66666	... ...	...
7	77777	... ...	...
8	88888	... ...	...
9	99999	... ...	...

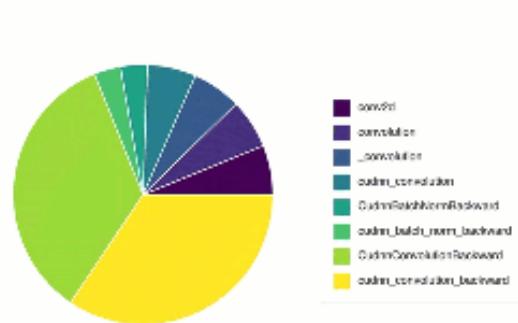

## Overview: GPU Operators

This section provides information of the GPU operators in detail. The table shows the percentage of the time and the absolute cumulative time spent on the most frequently called GPU operators.

## Overview: GPU operators

The following table shows a list of operators that your training job run on GPU. The most expensive operator on GPU was "CudnnConvolutionBackward" with 34 %.

#	Percentage	Cumulative time	GPU operator
0	34.48	189.9535	CustomConvolutionBatched
1	34.44	100.07210	custom_convolution_layer
2	6.18	94.9523	conv2d
3	5.13	24.73034	convolution
4	5.11	24.68905	convolution
5	5.06	24.44523	custom_convolution
6	3.84	19.87774	CustomBoxNormBackward
7	3.0	10.00003	custom_bwd_norm_layer

## Rules Summary

In this section, Debugger aggregates all of the rule evaluation results, analysis, rule descriptions, and suggestions.

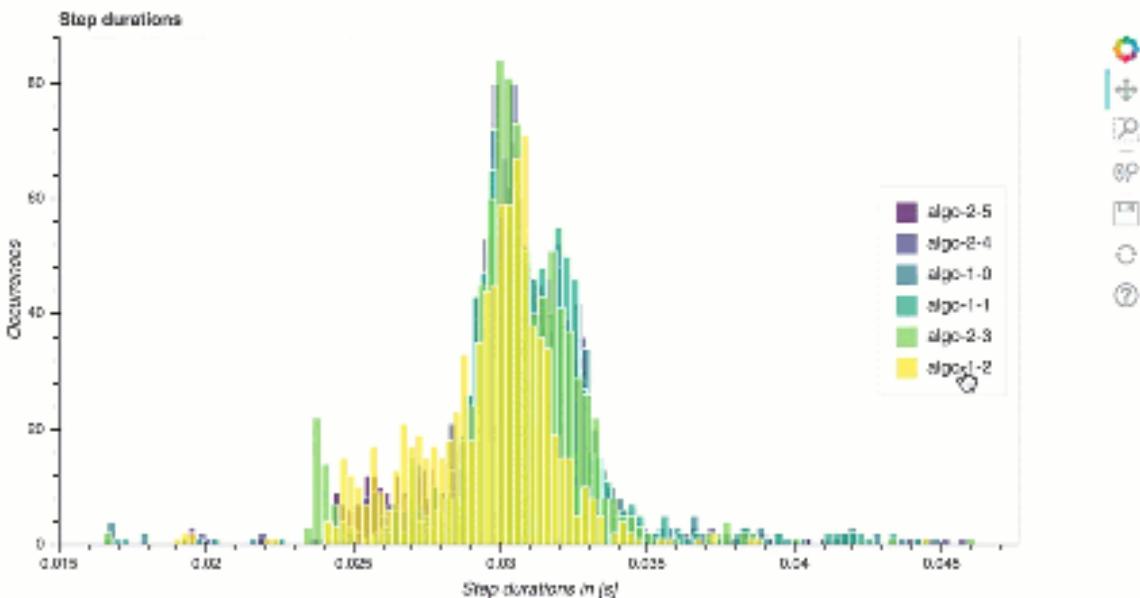

### **Ruler's Summary**

The following table lists the names of these 10 categories of the associated author names. The table is organized by the cause that triggered most frequently in your training data (the most frequent cause for each author). It has processed 5407 documents and suggested 503 times.

	Description	Implementation	Number of users who adopted	Number of users	Adopted percentage
TaskBoarding	Feature allows to automatically synchronize between multiple Gantt charts. Multitasking management can be increased as user can see and compare incoming tasks in parallel and prioritize them on priority basis. It also allows to quickly identify tasks which require urgent action without being affected by other tasks.	Create efficient multitasking strategy by effectively managing incoming tasks.	100	1000	100%
CostOptimization	Creates a Gantt chart to help you perform cost optimization. You can measure it based upon resources, team, budget and due date to identify inefficiencies or bottleneck activities.	Group all activities by resource planning code, change alternative planning strategy, increase batch size.	100	1000	100%
Reporting	Creates a Gantt chart to quickly review the duration and timing issues. To add it into the Gantt chart, the average Gantt currency (Resource, 25% and 40%) adjustment.	Run a quick analysis of your current Gantt chart.	100	1000	100%
Efficiency optimizer	A number which helps user to find major time wasting activities out of measured total time.	Create a report indicating tasks with lower efficiency. If it is not a resource limit or scope modification, fix it.	50	1000	50%
Efficiency optimizer	Create a Gantt chart to keep track of the using time. It helps to analyze a Gantt chart more deeply. It is used for better resource allocation.	Gantt chart helps to quickly identify overworking or idle workers.	100	1000	100%
Efficiency optimizer	A Gantt chart is a great tool for time saving (Gantt chart) to know, if they follow the Gantt chart. It is useful for tracking the progress of the project.	The Gantt chart is a visual representation of the project's tasks, their start and end dates, and dependencies.	50	1000	50%
Dashboard	Global portfolio risk detection. True for increased and enhanced quick decision making by using dashboards for learning. It shows real-time financial numbers to reveal indicators for more than 100 countries.	Create fast dashboard.	10	1000	1%
Dashboard	Creates a real time monitoring system to monitor your health care. The data comes from third party as well as own application in your own monitoring for the medical and 24/7 on dashboards to facilitate communication from different sources.	Dashboard for real time health.	5	1000	0.5%

## Analyzing the Training Loop – Step Durations

In this section, you can find a detailed statistics of step durations on each GPU core of each node. Debugger evaluates mean, maximum, p99, p95, p50, and minimum values of step durations, and evaluate step outliers. The following histogram shows the step durations captured on different worker nodes and GPUs. You can enable or disable the histogram of each worker by choosing the legends on the right side. You can check if there is a particular GPU that's causing step duration outliers.

## GPU Utilization Analysis

This section shows the detailed statistics about GPU core utilization based on LowGPUUtilization rule. It also summarizes the GPU utilization statistics, mean, p95, and p5 to determine if the training job is underutilizing GPUs.

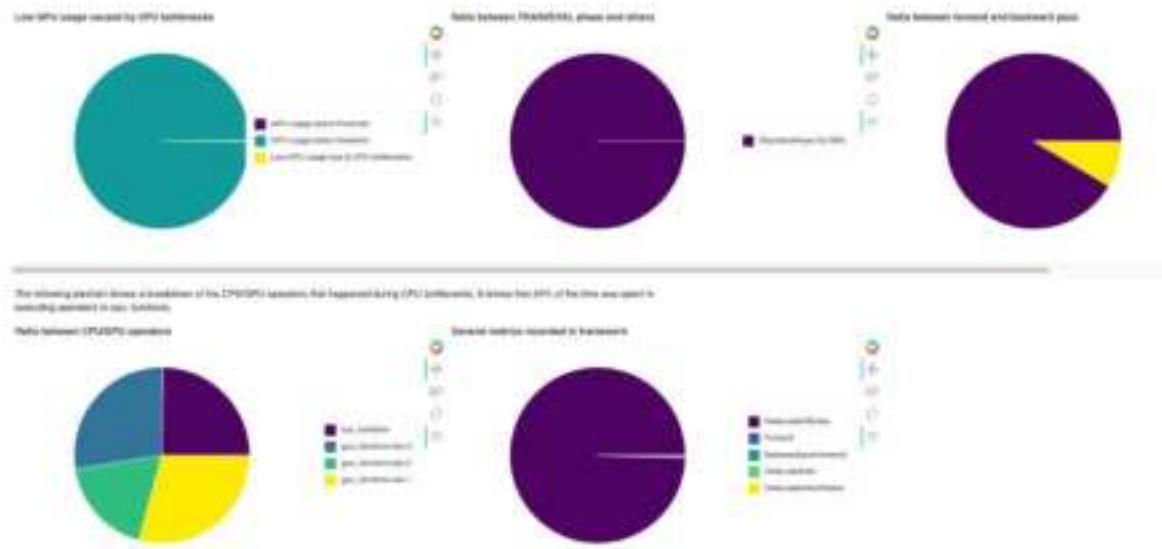

### Batch Size

This section shows the detailed statistics of total CPU utilization, individual GPU utilizations, and GPU memory footprints. The BatchSize rule determines if you need to change the batch size to better utilize the GPUs. You can check whether the batch size is too small resulting in underutilization or too large causing overutilization and out of memory issues. In the plot, the boxes show the p25 and p75 percentile ranges (filled with dark purple and bright yellow respectively) from the median (p50), and the error bars show the 5th percentile for the lower bound and 95th percentile for the upper bound.

## CPU Bottlenecks

In this section, you can drill down into the CPU bottlenecks that the CPUBottleneck rule detected from your training job. The rule checks if the CPU utilization is above `cpu_threshold` (90% by default) and also if the GPU utilization is below `gpu_threshold` (10% by default).

The pie charts show the following information:

- Low GPU usage caused by CPU bottlenecks** – Shows the ratio of data points between the ones with GPU utilization above and below the threshold and the ones that matches the CPU bottleneck criteria.
- Ratio between TRAIN/EVAL phase and others** – Shows the ratio between time durations spent on different training phases.
- Ratio between forward and backward pass** – Shows the ratio between time durations spent on forward and backward pass in the training loop.

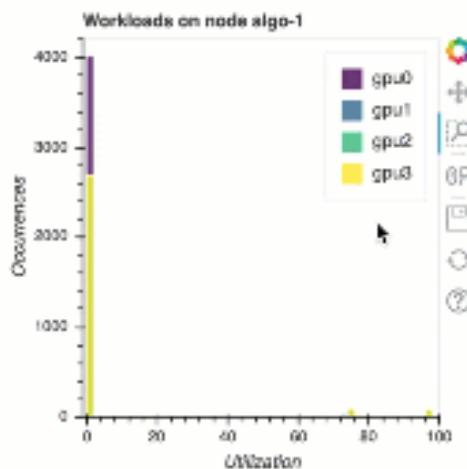

- **Ratio between CPU/GPU operators** – Shows the ratio between time durations spent on GPUs and CPUs by Python operators, such as data loader processes and forward and backward pass operators.
- **General metrics recorded in framework** – Shows major framework metrics and the ratio between time durations spent on the metrics.

## I/O Bottlenecks

In this section, you can find a summary of IO bottlenecks.

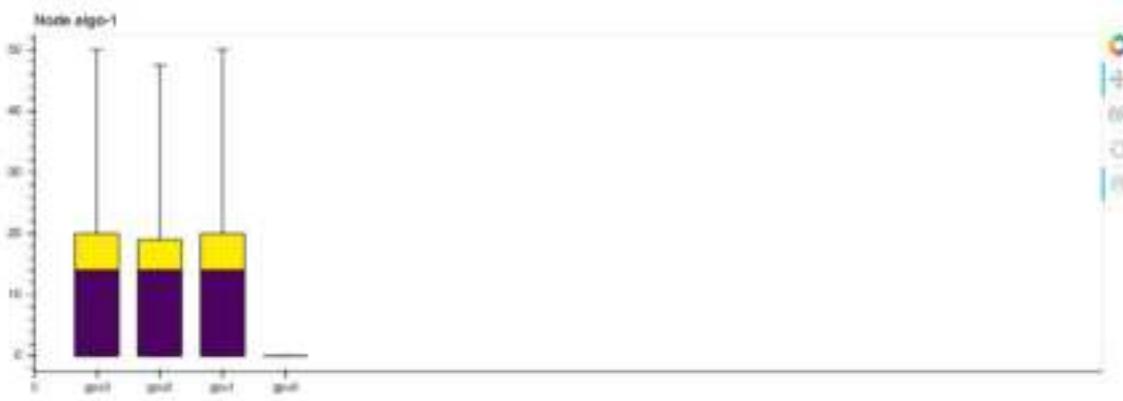

### LoadBalancing in Multi-GPU Training

In this section, you can identify workload balancing issue across GPUs.

## GPU Memory Analysis

In this section, you can analyze the GPU memory utilization collected by the GPUMemoryIncrease rule. In the plot, the boxes show the p25 and p75 percentile ranges (filled with dark purple and bright yellow respectively) from the median (p50), and the error bars show the 5th percentile for the lower bound and 95th percentile for the upper bound.

## SageMaker Debugger XGBoost Training Report

For SageMaker XGBoost training jobs, use the Debugger [CreateXgboostReport \(p. 1638\)](#) rule to receive a comprehensive training report of the training progress and results. Following this guide, specify the [CreateXgboostReport \(p. 1638\)](#) rule while constructing an XGBoost estimator, download the report using

the [Amazon SageMaker Python SDK](#) or the Amazon S3 console, and then you can interpret the profiling results.

### Topics

- [Construct a SageMaker XGBoost Estimator with the Debugger XGBoost Report Rule \(p. 1712\)](#)
- [Download the Debugger XGBoost Training Report \(p. 1713\)](#)
- [Debugger XGBoost Training Report Walkthrough \(p. 1715\)](#)

## Construct a SageMaker XGBoost Estimator with the Debugger XGBoost Report Rule

When you construct a SageMaker estimator for an XGBoost training job, specify the rule as shown in the following example code.

The [CreateXgboostReport \(p. 1638\)](#) rule collects the following output tensors from your training job:

- `hyperparameters` – Saves at the first step.
- `metrics` – Saves loss and accuracy every 5 steps.
- `feature_importance` – Saves every 5 steps.
- `predictions` – Saves every 5 steps.
- `labels` – Saves every 5 steps.

The output tensors are saved at a default S3 bucket. For example, `s3://sagemaker-<region>-<12digit_account_id>/<base-job-name>/debug-output/`.

Using the SageMaker generic estimator

```
import boto3
import sagemaker
from sagemaker.estimator import Estimator
from sagemaker import image_uris
from sagemaker.debugger import Rule, rule_configs

rules=[
    Rule.sagemaker(rule_configs.create_xgboost_report())
]

region = boto3.Session().region_name
xgboost_container=sagemaker.image_uris.retrieve("xgboost", region, "1.2-1")

estimator=Estimator(
    role=sagemaker.get_execution_role()
    image_uri=xgboost_container,
    base_job_name="debugger-xgboost-report-demo",
    instance_count=1,
    instance_type="ml.m5.2xlarge",

    # Add the Debugger XGBoost report rule
    rules=rules
)

estimator.fit(wait=False)
```

## Download the Debugger XGBoost Training Report

Download the Debugger XGBoost training report while your training job is running or after the job has finished using the [Amazon SageMaker Python SDK](#) and Amazon Command Line Interface (CLI).

Download using the SageMaker Python SDK and Amazon CLI

1. Check the current job's default S3 output base URI.

```
estimator.output_path
```

2. Check the current job name.

```
estimator.latest_training_job.job_name
```

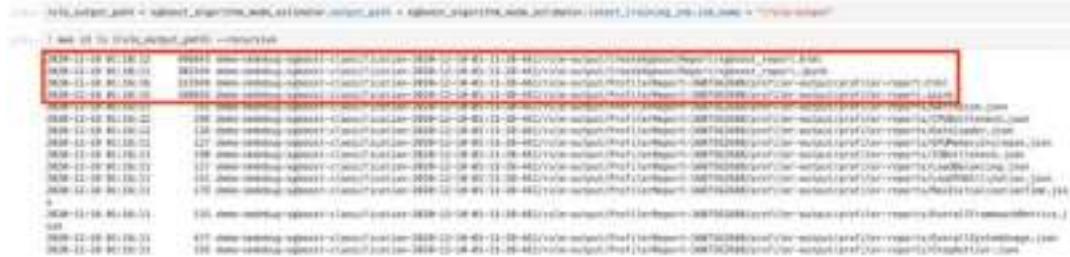

3. The Debugger XGBoost report is stored under <default-s3-output-base-uri>/<training-job-name>/rule-output. Configure the rule output path as follows:

```
rule_output_path = estimator.output_path + estimator.latest_training_job.job_name +  
    "/rule-output"
```

4. To check if the report is generated, list directories and files recursively under the rule\_output\_path using aws s3 ls with the --recursive option.

```
! aws s3 ls {rule_output_path} --recursive
```

This should return a complete list of files under autogenerated folders that are named CreateXgboostReport and ProfilerReport-1234567890. The XGBoost training report is stored in the CreateXgboostReport, and the profiling report is stored in the ProfilerReport-1234567890 folder. To learn more about the profiling report generated by default with the XGBoost training job, see [SageMaker Debugger Profiling Report \(p. 1701\)](#).

The xgboost\_report.html is an autogenerated XGBoost training report by Debugger. The xgboost\_report.ipynb is a Jupyter notebook that's used to aggregate training results into the report. You can download all of the files, browse the HTML report file, and modify the report using the notebook.

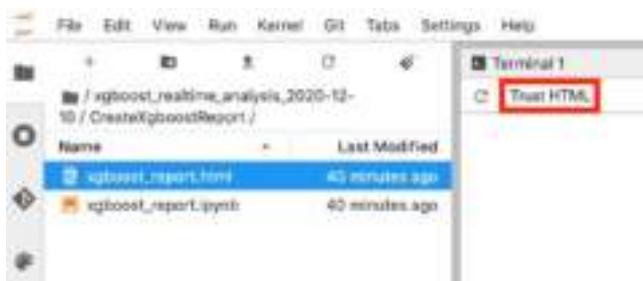

5. Download the files recursively using aws s3 cp. The following command saves all of the rule output files to the ProfilerReport-1234567890 folder under the current working directory.

```
! aws s3 cp {rule_output_path} ./ --recursive
```

### Tip

If you are using a Jupyter notebook server, run !pwd to verify the current working directory.

6. Under the /CreateXgboostReport directory, open xgboost\_report.html. If you are using JupyterLab, choose **Trust HTML** to see the autogenerated Debugger training report.

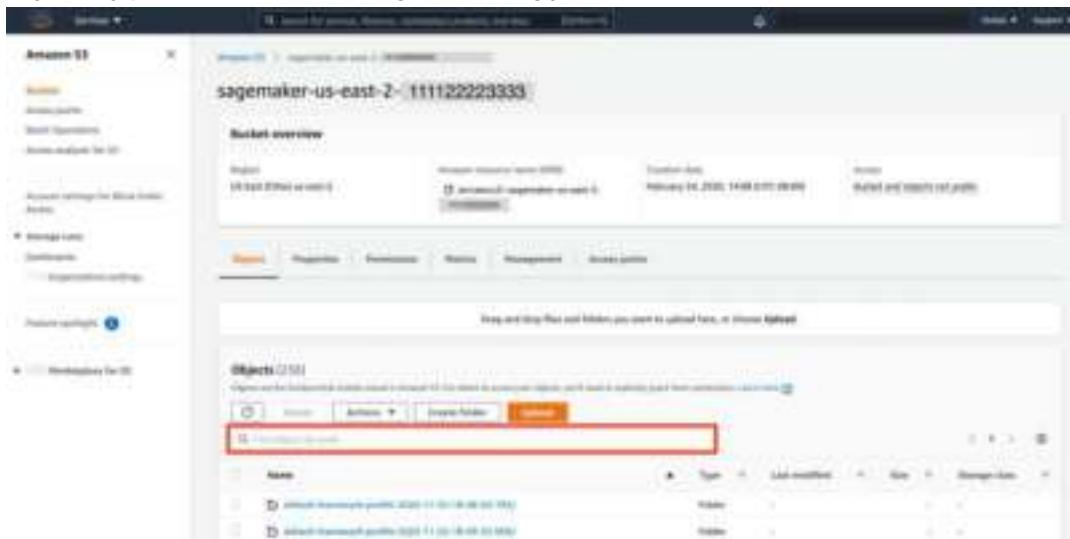

7. Open the `xgboost_report.ipynb` file to explore how the report is generated. You can customize and extend the training report using the Jupyter notebook file.

Download using the Amazon S3 console

1. Sign in to the Amazon Web Services Management Console and open the Amazon S3 console at <https://console.amazonaws.cn/s3/>.
2. Search for the base S3 bucket. For example, if you haven't specified any base job name, the base S3 bucket name should be in the following format: `sagemaker-<region>-111122223333`. Look up the base S3 bucket through the **Find bucket by name** field.

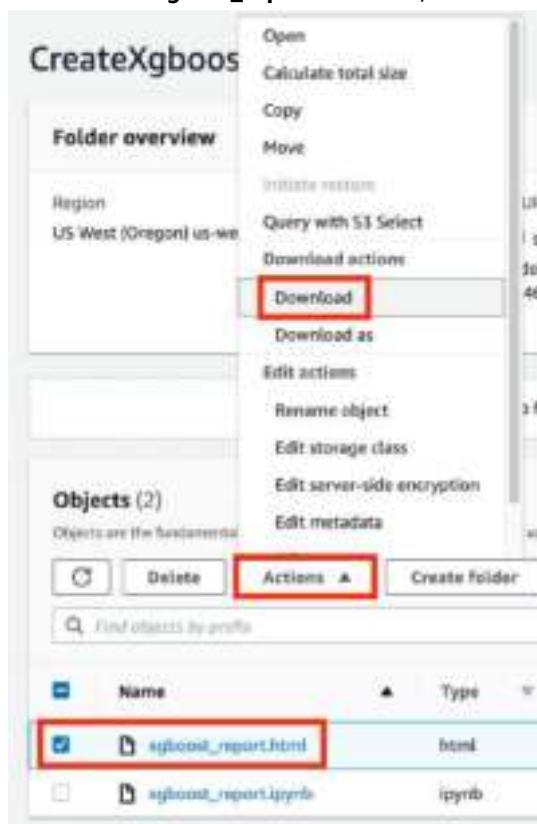

3. In the base S3 bucket, look up the training job name by entering your job name prefix in **Find objects by prefix** and then choosing the training job name.

4. In the training job's S3 bucket, choose **rule-output/** subfolder. There must be three subfolders for training data collected by Debugger: **debug-output/**, **profiler-output/**, and **rule-output/**.

5. In the **rule-output/** folder, choose the **CreateXgboostReport/** folder. The folder contains **xbgoost\_report.html** (the autogenerated report in html) and **xbgoost\_report.ipynb** (a Jupyter notebook with scripts that are used for generating the report).
6. Choose the **xbgoost\_report.html** file, choose **Download actions**, and then choose **Download**.

7. Open the downloaded **xbgoost\_report.html** file in a web browser.

## Debugger XGBoost Training Report Walkthrough

This section walks you through the Debugger XGBoost training report. The report is automatically aggregated depending on the output tensor regex, recognizing what type of your training job is among binary classification, multiclass classification, and regression.

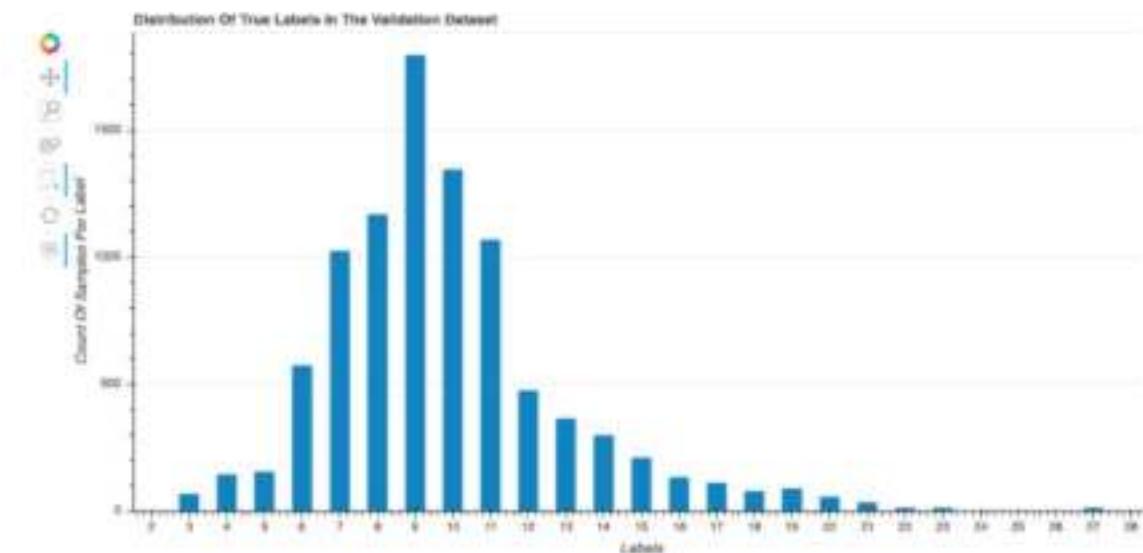

### Topics

- [Distribution of True Labels of the Dataset \(p. 1716\)](#)
- [Loss versus Step Graph \(p. 1716\)](#)

- [Feature Importance \(p. 1717\)](#)
- [Confusion Matrix \(p. 1718\)](#)
- [Evaluation of the Confusion Matrix \(p. 1719\)](#)
- [Accuracy Rate of Each Diagonal Element Over Iteration \(p. 1720\)](#)
- [Receiver Operating Characteristic Curve \(p. 1721\)](#)
- [Distribution of Residuals at the Last Saved Step \(p. 1722\)](#)
- [Absolute Validation Error per Label Bin Over Iteration \(p. 1723\)](#)

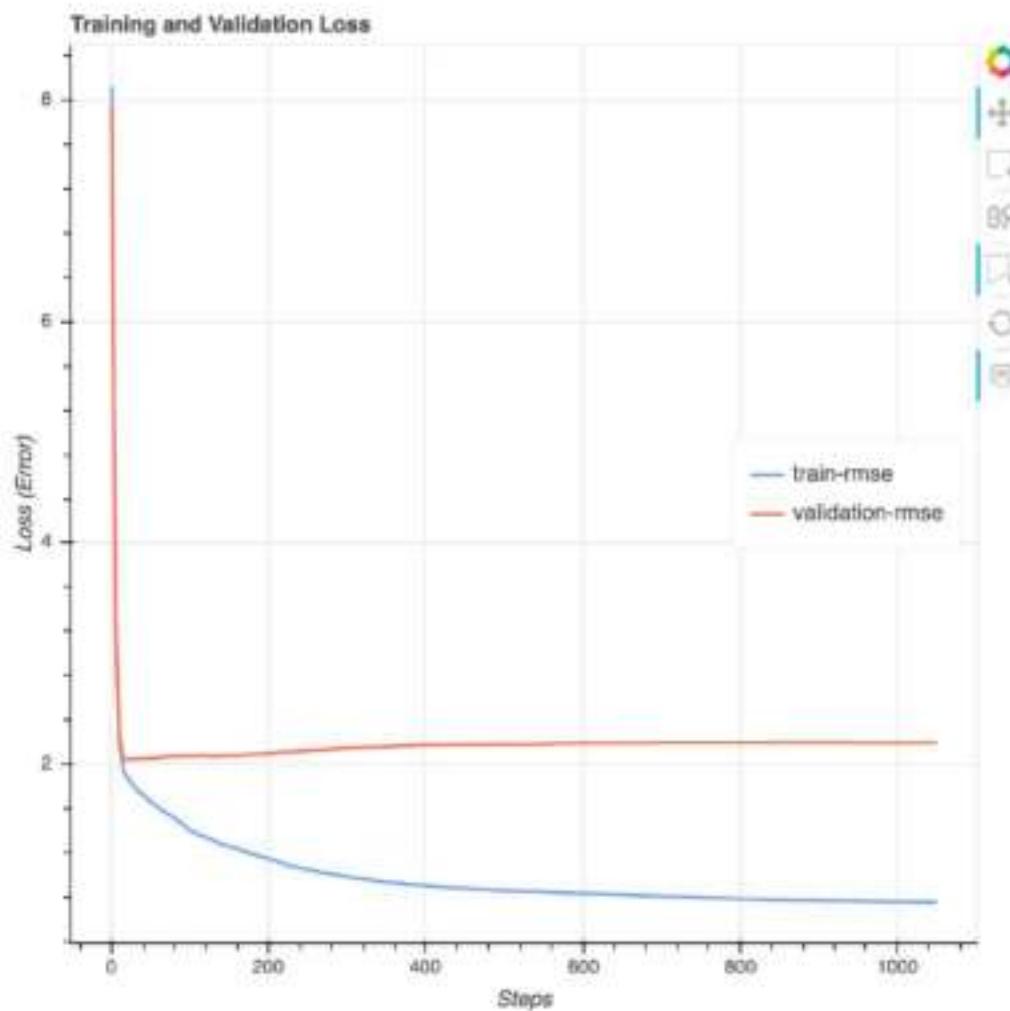

### Distribution of True Labels of the Dataset

This histogram shows the distribution of labeled classes (for classification) or values (for regression) in your original dataset. Skewness in your dataset could contribute to inaccuracies. This visualization is available for the following model types: binary classification, multiclassification, and regression.

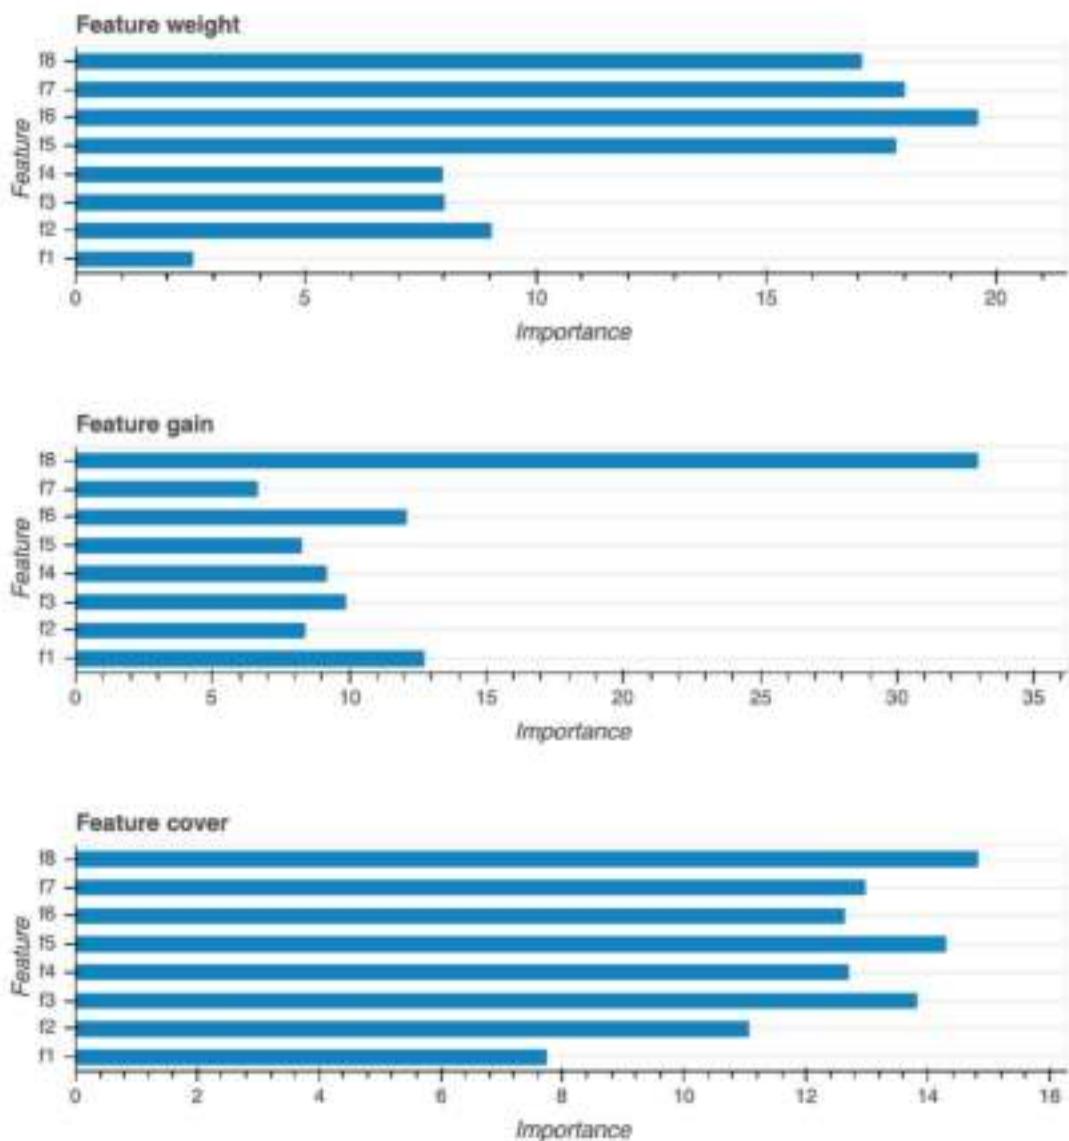

### Loss versus Step Graph

This is a line chart that shows the progression of loss on training data and validation data throughout training steps. The loss is what you defined in your objective function, such as mean squared error. You can gauge whether the model is overfit or underfit from this plot. This section also provides insights that you can use to determine how to resolve the overfit and underfit problems. This visualization is available for the following model types: binary classification, multiclassification, and regression.

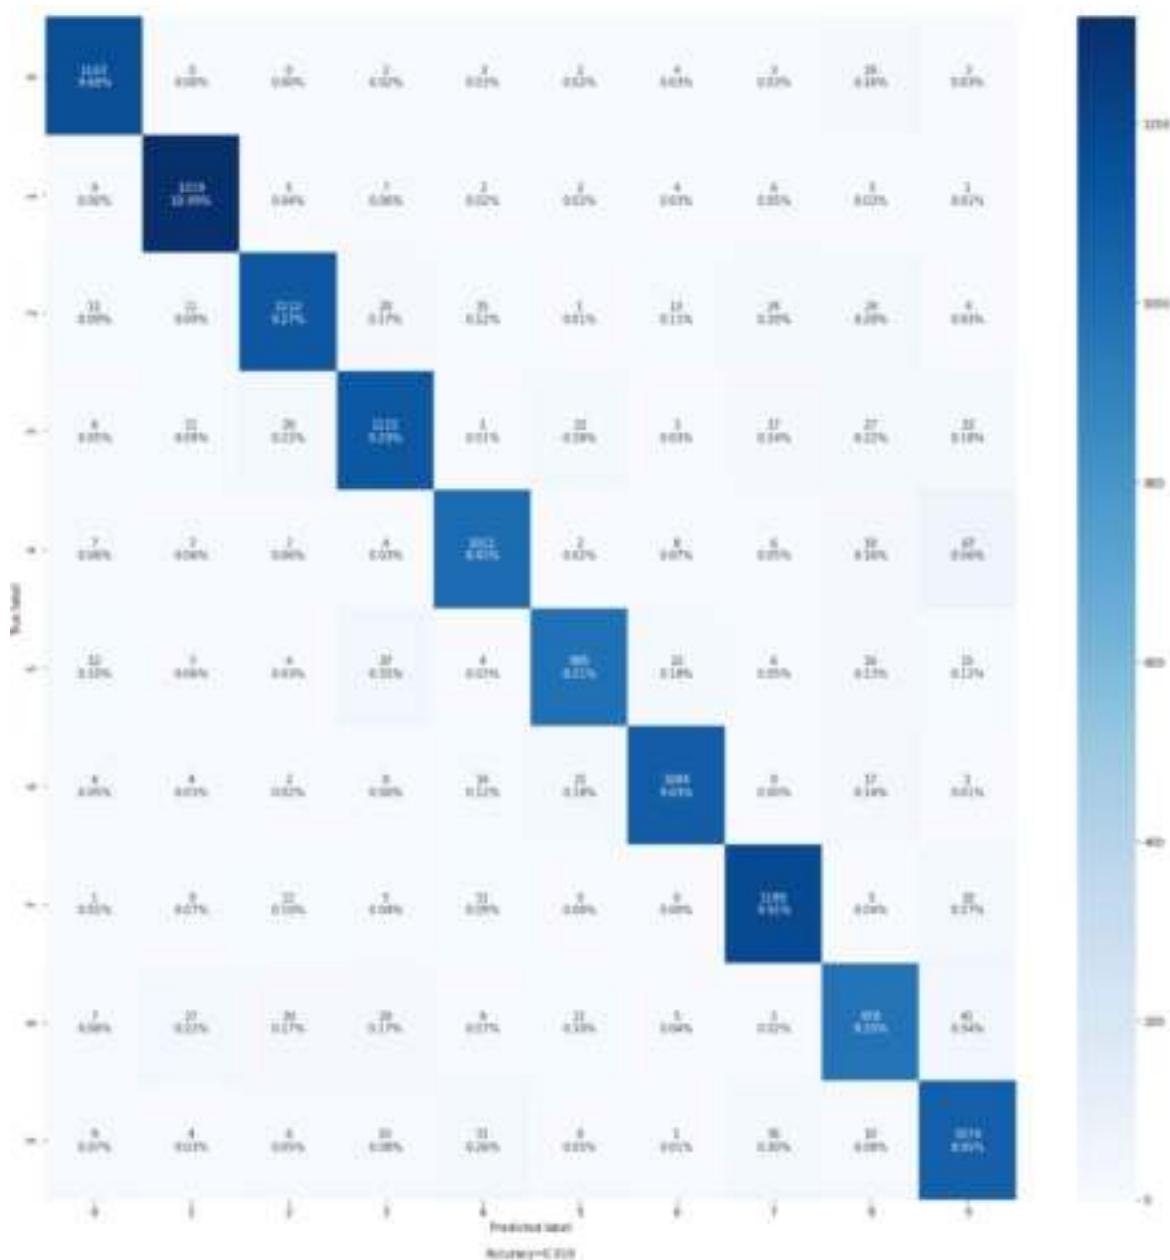

## Feature Importance

There are three different types of feature importance visualizations provided: Weight, Gain and Coverage. We provide detailed definitions for each of the three in the report. Feature importance visualizations help you learn what features in your training dataset contributed to the predictions. Feature importance visualizations are available for the following model types: binary classification, multiclassification, and regression.

## Confusion Matrix

This visualization is only applicable to binary and multiclass classification models. Accuracy alone might not be sufficient for evaluating the model performance. For some use cases, such as healthcare and fraud detection, it's also important to know the false positive rate and false negative rate. A confusion matrix gives you the additional dimensions for evaluating your model performance.

### Evaluation of the Confusion Matrix

This section provides you with more insights on the micro, macro, and weighted metrics on precision, recall, and F1-score for your model.

**Overall Accuracy**

Overall Accuracy: 0.919

**Micro Performance Metrics**

Performance metrics calculated globally by counting the total true positives, false negatives, and false positives.

Micro Precision: 0.919

Micro Recall: 0.919

Micro F1-score: 0.919

**Macro Performance Metrics**

Performance metrics calculated for each label, and find their unweighted mean.  
This does not take the class imbalance problem into account.

Macro Precision: 0.918

Macro Recall: 0.918

Macro F1-score: 0.918

**Weighted Performance Metrics**

Performance metrics calculated for each label and their average weighted by support  
(the number of true instances for each label).  
This extends the macro option to take the class imbalance into account.  
It might result in an F-score that is not between precision and recall.

Weighted Precision: 0.92

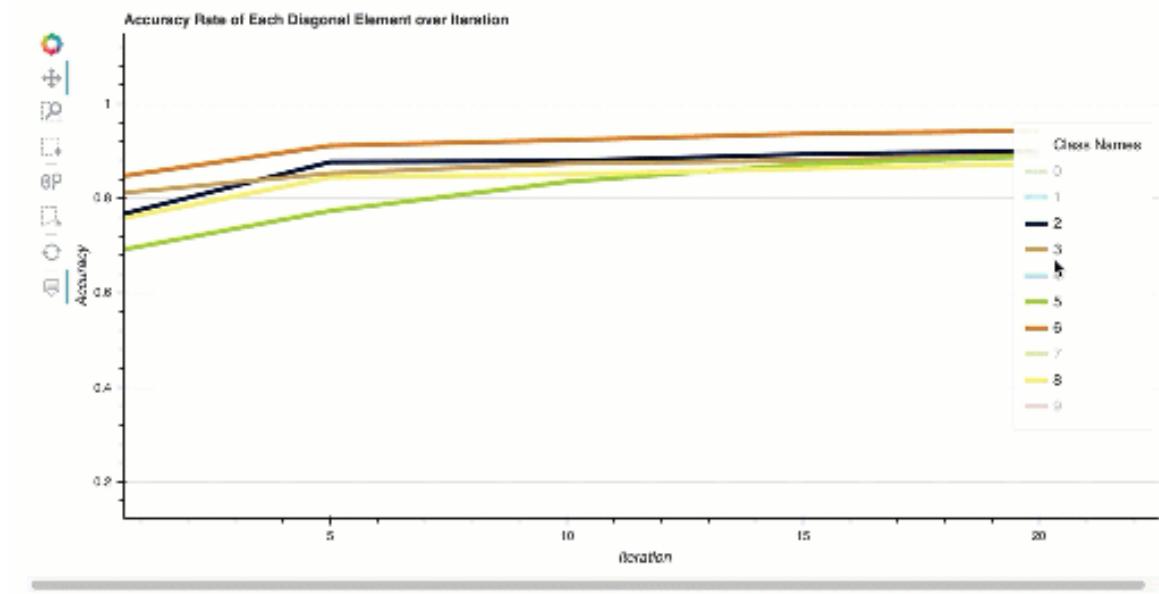

Weighted Recall: 0.919

Weighted F1-score: 0.919

**Classification Report**

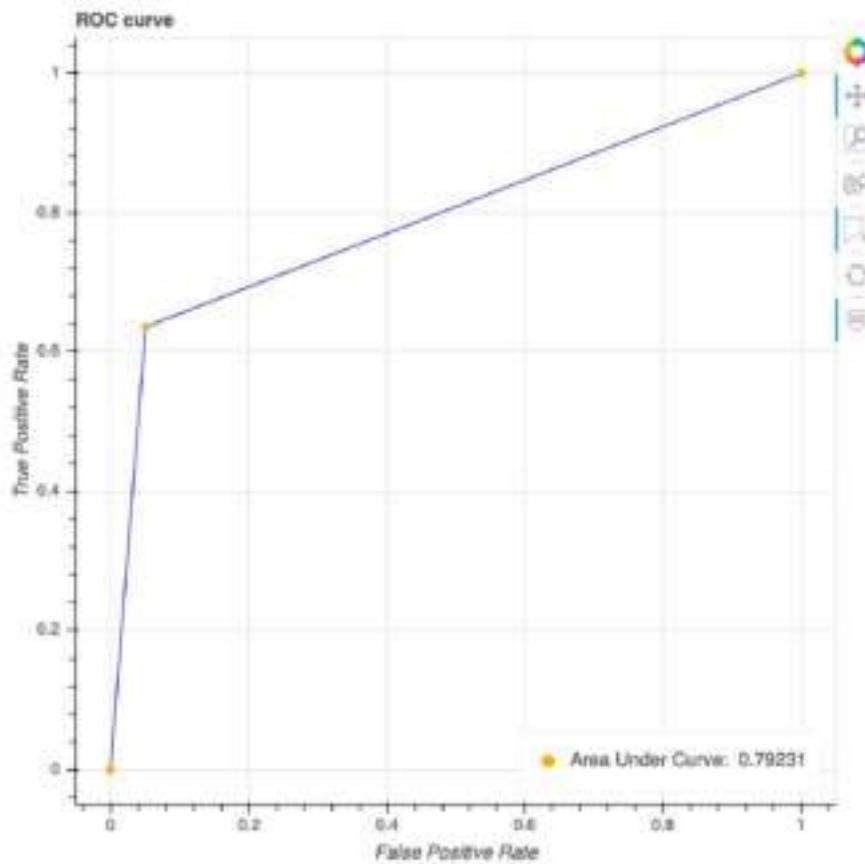

The summary of the precision, recall, and F1-score for each class.

	precision	recall	f1-score	support
0.0	0.95	0.97	0.96	1199
1.0	0.94	0.98	0.96	1349
2.0	0.93	0.98	0.92	1235
3.0	0.91	0.99	0.90	1250
4.0	0.92	0.99	0.90	1138
5.0	0.94	0.99	0.93	1108
6.0	0.95	0.94	0.95	1149
7.0	0.92	0.98	0.93	1264
8.0	0.87	0.87	0.87	1121
9.0	0.89	0.99	0.88	1187
accuracy			0.92	12000
macro avg	0.92	0.92	0.92	12000
weighted avg	0.92	0.92	0.92	12000

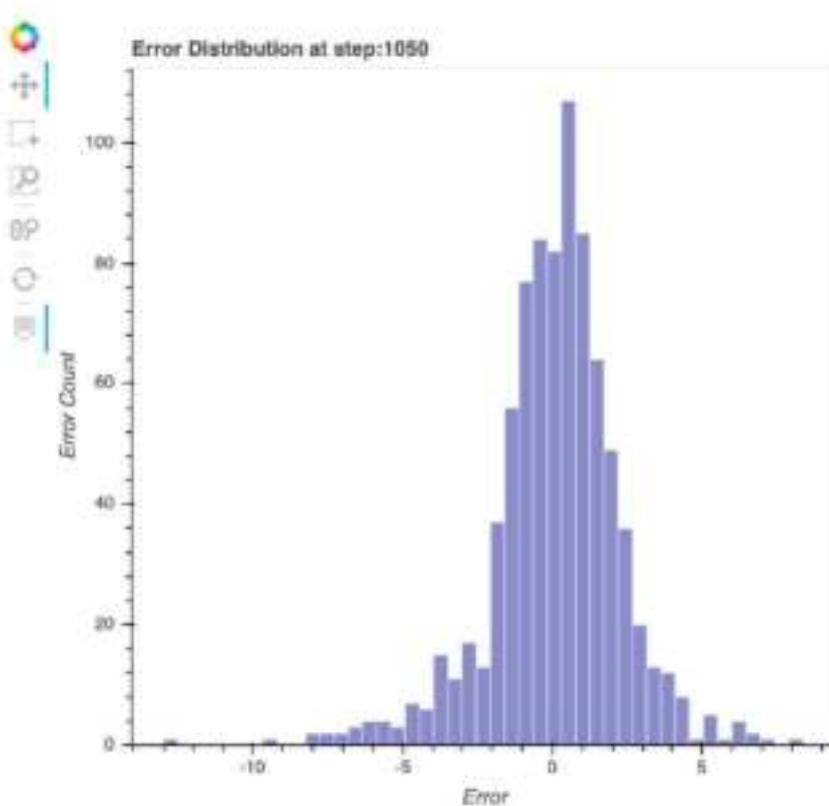

### Receiver Operating Characteristic Curve

This visualization is only applicable to binary classification models. The Receiver Operating Characteristic curve is commonly used to evaluate binary classification model performance. The y-axis of the curve is True Positive Rate (TPR) and x-axis is false positive rate (FPR). The plot also displays the value for the area under the curve (AUC). The higher the AUC value, the more predictive your classifier. You can also use the ROC curve to understand the trade-off between TPR and FPR and identify the optimum classification threshold for your use case. The classification threshold can be adjusted to tune the behavior of the model to reduce more of one or another type of error (FP/FN).

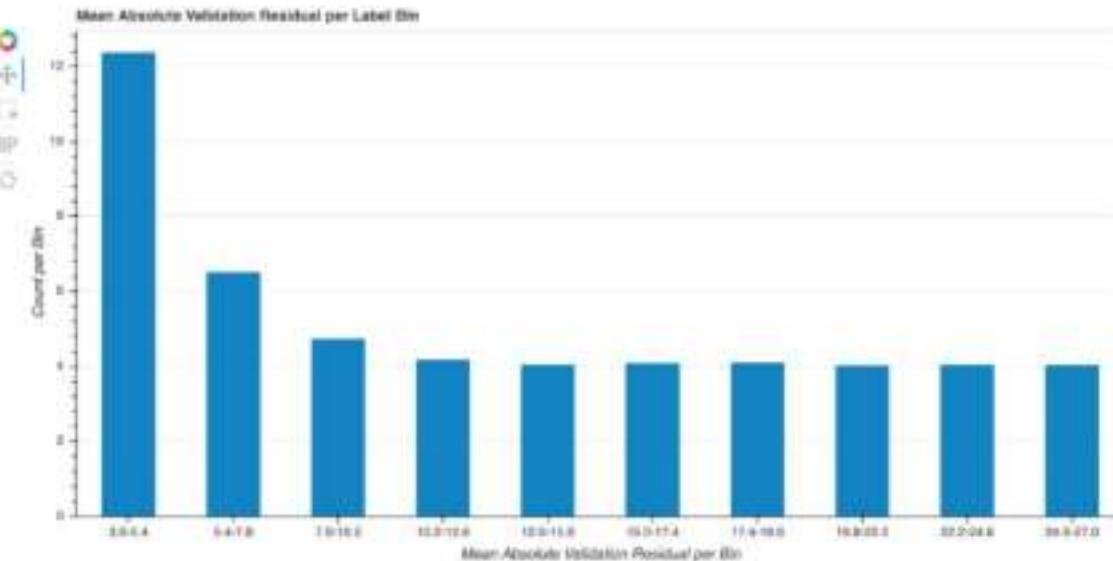

### Distribution of Residuals at the Last Saved Step

This visualization is a column chart that shows the residual distributions in the last step Debugger captures. In this visualization, you can check whether the residual distribution is close to normal distribution that's centered at zero. If the residuals are skewed, your features may not be sufficient for predicting the labels.

#### Absolute Validation Error per Label Bin Over Iteration

This visualization is only applicable to regression models. The actual target values are split into 10 intervals. This visualization shows how validation errors progress for each interval throughout the training steps in line plots. Absolute validation error is the absolute value of difference between prediction and actual during validation. You can identify the underperforming intervals from this visualization.

# Analyze Data Using the SMDebug Client Library

While your training job is running or after it has completed, you can access the training data collected by Debugger using the [Amazon SageMaker Python SDK](#) and the [SMDebug client library](#). The SMDebug library provides analysis and visualization tools that enable you to drill down into your training job data.

**To install the library and use the SMDebug analysis tools (in a JupyterLab notebook or an iPython kernel)**

```
! pip install -U smdebug
```

The following topics walk you through how to use the SMDebug tools to visualize and analyze the training data collected by Debugger.

## Analyze system and framework metrics

- [Access the Monitoring and Profiling Data \(p. 1724\)](#)
- [Plot the System Metrics and Framework Metrics Data \(p. 1725\)](#)
- [Access the Profiling Data Using the Pandas Data Parsing Tool \(p. 1726\)](#)
- [Access the Python Profiling Stats Data \(p. 1726\)](#)
- [Merge Timelines of Different Profiling Trace Files \(p. 1729\)](#)
- [Profiling Data Loader \(p. 1731\)](#)

## Access the Monitoring and Profiling Data

The SMDebug `TrainingJob` class reads data from the S3 bucket where the system and framework metrics are saved.

**To set up a `TrainingJob` object and retrieve profiling event files of a training job**

```
from smdebug.profiler.analysis.notebook_utils.training_job import TrainingJob
tj = TrainingJob(training_job_name, region)
```

### Tip

You need to specify the `training_job_name` and `region` parameters to log to a training job. There are two ways to specify the training job information:

- Use the SageMaker Python SDK while the estimator is still attached to the training job.

```
import sagemaker
training_job_name=estimator.latest_training_job.job_name
region=sagemaker.Session().boto_region_name
```

- Pass strings directly.

```
training_job_name="your-training-job-name-YYYY-MM-DD-HH-MM-SS-SSS"
region="us-west-2"
```

**To retrieve a description of the training job description and the S3 bucket URI where the metric data are saved**

```
tj.describe_training_job()
tj.get_config_and_profiler_s3_output_path()
```

### To check if the system and framework metrics are available from the S3 URI

```
tj.wait_for_sys_profiling_data_to_be_available()  
tj.wait_for_framework_profiling_data_to_be_available()
```

### To create system and framework reader objects after the metric data become available

```
system_metrics_reader = tj.get_systems_metrics_reader()  
framework_metrics_reader = tj.get_framework_metrics_reader()
```

### To refresh and retrieve the latest training event files

The reader objects have an extended method, `refresh_event_file_list()`, to retrieve the latest training event files.

```
system_metrics_reader.refresh_event_file_list()  
framework_metrics_reader.refresh_event_file_list()
```

## Plot the System Metrics and Framework Metrics Data

You can use the system and algorithm metrics objects for the following visualization classes to plot timeline graphs and histograms.

#### Note

To visualize the data with narrowed-down metrics in the following visualization object plot methods, specify `select_dimensions` and `select_events` parameters. For example, if you specify `select_dimensions=[ "GPU" ]`, the plot methods filter the metrics that include the "GPU" keyword. If you specify `select_events=[ "total" ]`, the plot methods filter the metrics that include the "total" event tags at the end of the metric names. If you enable these parameters and give the keyword strings, the visualization classes return the charts with filtered metrics.

- The `MetricsHistogram` class

```
from smdebug.profiler.analysis.notebook_utils.metrics_histogram import MetricsHistogram  
  
metrics_histogram = MetricsHistogram(system_metrics_reader)  
metrics_histogram.plot(  
    starttime=0,  
    endtime=system_metrics_reader.get_timestamp_of_latest_available_file(),  
    select_dimensions=[ "CPU", "GPU", "I/O" ], # optional  
    select_events=[ "total" ] # optional  
)
```

- The `StepTimelineChart` class

```
from smdebug.profiler.analysis.notebook_utils.step_timeline_chart import  
StepTimelineChart  
  
view_step_timeline_chart = StepTimelineChart(framework_metrics_reader)
```

- The `StepHistogram` class

```
from smdebug.profiler.analysis.notebook_utils.step_histogram import StepHistogram  
  
step_histogram = StepHistogram(framework_metrics_reader)  
step_histogram.plot(  
    starttime=step_histogram.last_timestamp - 5 * 1000 * 1000,
```

```
|     endtime=step_histogram.last_timestamp,  
|     show_workers=True  
)
```

- The `TimelineCharts` class

```
from smdebug.profiler.analysis.notebook_utils.timeline_charts import TimelineCharts  
  
view_timeline_charts = TimelineCharts(  
    system_metrics_reader,  
    framework_metrics_reader,  
    select_dimensions=["CPU", "GPU", "I/O"], # optional  
    select_events=["total"] # optional  
)  
  
view_timeline_charts.plot_detailed_profiler_data([700,710])
```

- The `Heatmap` class

```
from smdebug.profiler.analysis.notebook_utils.heatmap import Heatmap  
  
view_heatmap = Heatmap(  
    system_metrics_reader,  
    framework_metrics_reader,  
    select_dimensions=["CPU", "GPU", "I/O"], # optional  
    select_events=["total"], # optional  
    plot_height=450  
)
```

## Access the Profiling Data Using the Pandas Data Parsing Tool

The following `PandasFrame` class provides tools to convert the collected profiling data to Pandas data frame.

```
from smdebug.profiler.analysis.utils.profiler_data_to_pandas import PandasFrame
```

The `PandasFrame` class takes the `tj` object's S3 bucket output path, and its methods `get_all_system_metrics()` `get_all_framework_metrics()` return system metrics and framework metrics in the Pandas data format.

```
pf = PandasFrame(tj.profiler_s3_output_path)  
system_metrics_df = pf.get_all_system_metrics()  
framework_metrics_df = pf.get_all_framework_metrics()  
selected_framework_metrics=[  
    'Step:ModeKeys.TRAIN',  
    'Step:ModeKeys.GLOBAL'  
]  
)
```

## Access the Python Profiling Stats Data

The Python profiling provides framework metrics related to Python functions and operators in your training scripts and the SageMaker deep learning frameworks.

### Training Modes and Phases for Python Profiling

To profile specific intervals during training to partition statistics for each of these intervals, Debugger provides tools to set modes and phases.

For training modes, use the following `PythonProfileModes` class:

```
from smdebug.profiler.python_profile_utils import PythonProfileModes
```

This class provides the following options:

- `PythonProfileModes.TRAIN` – Use if you want to profile the target steps in the training phase. This mode option available only for TensorFlow.
- `PythonProfileModes.EVAL` – Use if you want to profile the target steps in the evaluation phase. This mode option available only for TensorFlow.
- `PythonProfileModes.PREDICT` – Use if you want to profile the target steps in the prediction phase. This mode option available only for TensorFlow.
- `PythonProfileModes.GLOBAL` – Use if you want to profile the target steps in the global phase, which includes the previous three phases. This mode option available only for PyTorch.
- `PythonProfileModes.PRE_STEP_ZERO` – Use if you want to profile the target steps in the initialization stage before the first training step of the first epoch starts. This phase includes the initial job submission, uploading the training scripts to EC2 instances, preparing the EC2 instances, and downloading input data. This mode option available for both TensorFlow and PyTorch.
- `PythonProfileModes.POST_HOOK_CLOSE` – Use if you want to profile the target steps in the finalization stage after the training job has done and the Debugger hook is closed. This phase includes profiling data while the training jobs are finalized and completed. This mode option available for both TensorFlow and PyTorch.

For training phases, use the following `StepPhase` class:

```
from smdebug.profiler.analysis.utils.python_profile_analysis_utils import StepPhase
```

This class provides the following options:

- `StepPhase.START` – Use to specify the start point of the initialization phase.
- `StepPhase.STEP_START` – Use to specify the start step of the training phase.
- `StepPhase.FORWARD_PASS_END` – Use to specify the steps where the forward pass ends. This option is available only for PyTorch.
- `StepPhase.STEP_END` – Use to specify the end steps in the training phase. This option is available only for TensorFlow.
- `StepPhase.END` – Use to specify the ending point of the finalization (post-hook-close) phase. If the callback hook is not closed, the finalization phase profiling does not occur.

## Python Profiling Analysis Tools

Debugger supports the Python profiling with two profiling tools:

- `cProfile` – The standard python profiler. `cProfile` collects framework metrics on CPU time for every function called when profiling was enabled.
- `Pyinstrument` – This is a low overhead Python profiler sampling profiling events every milliseconds.

To learn more about the Python profiling options and what's collected, see [Start a Training Job with the Default System Monitoring and Customized Framework Profiling with Different Profiling Options \(p. 1600\)](#).

The following methods of the `PythonProfileAnalysis`, `cProfileAnalysis`, `PyinstrumentAnalysis` classes are provided to fetch and analyze the Python profiling data. Each function loads the latest data from the default S3 URI.

```
from smdebug.profiler.analysis.python_profile_analysis import PythonProfileAnalysis,  
cProfileAnalysis, PyinstrumentAnalysis
```

To set Python profiling objects for analysis, use the `cProfileAnalysis` or `PyinstrumentAnalysis` classes as shown in the following example code. It shows how to set a `cProfileAnalysis` object, and if you want to use `PyinstrumentAnalysis`, replace the class name.

```
python_analysis = cProfileAnalysis(  
    local_profile_dir=tf_python_stats_dir,  
    s3_path=tj.profiler_s3_output_path  
)
```

The following methods are available for the `cProfileAnalysis` and `PyinstrumentAnalysis` classes to fetch the Python profiling stats data:

- `python_analysis.fetch_python_profile_stats_by_time(start_time_since_epoch_in_secs, end_time_since_epoch_in_secs)` – Takes in a start time and end time, and returns the function stats of step stats whose start or end times overlap with the provided interval.
- `python_analysis.fetch_python_profile_stats_by_step(start_step, end_step, mode, start_phase, end_phase)` – Takes in a start step and end step and returns the function stats of all step stats whose profiled step satisfies `start_step <= step < end_step`.
  - `start_step` and `end_step` (str) – Specify the start step and end step to fetch the Python profiling stats data.
  - `mode` (str) – Specify the mode of training job using the `PythonProfileModes` enumerator class. The default is `PythonProfileModes.TRAIN`. Available options are provided in the [Training Modes and Phases for Python Profiling \(p. 1726\)](#) section.
  - `start_phase` (str) – Specify the start phase in the target step(s) using the `StepPhase` enumerator class. This parameter enables profiling between different phases of training. The default is `StepPhase.STEP_START`. Available options are provided in the [Training Modes and Phases for Python Profiling \(p. 1727\)](#) section.
  - `end_phase` (str) – Specify the end phase in the target step(s) using the `StepPhase` enumerator class. This parameter sets up the end phase of training. Available options are as same as the ones for the `start_phase` parameter. The default is `StepPhase.STEP_END`. Available options are provided in the [Training Modes and Phases for Python Profiling \(p. 1727\)](#) section.
- `python_analysis.fetch_profile_stats_between_modes(start_mode, end_mode)` – Fetches stats from the Python profiling between the start and end modes.
- `python_analysis.fetch_pre_step_zero_profile_stats()` – Fetches the stats from the Python profiling until step 0.
- `python_analysis.fetch_post_hook_close_profile_stats()` – Fetches stats from the Python profiling after the hook is closed.
- `python_analysis.list_profile_stats()` – Returns a DataFrame of the Python profiling stats. Each row holds the metadata for each instance of profiling and the corresponding stats file (one per step).
- `python_analysis.list_available_node_ids()` – Returns a list the available node IDs for the Python profiling stats.

The `cProfileAnalysis` class specific methods:

- `fetch_profile_stats_by_training_phase()` – Fetches and aggregates the Python profiling stats for every possible combination of start and end modes. For example, if a training and validation phases are done while detailed profiling is enabled, the combinations are `(PRE_STEP_ZERO, TRAIN)`, `(TRAIN, TRAIN)`, `(TRAIN, EVAL)`, `(EVAL, EVAL)`, and `(EVAL, POST_HOOK_CLOSE)`. All stats files within each of these combinations are aggregated.

- `fetch_profile_stats_by_job_phase()` – Fetches and aggregates the Python profiling stats by job phase. The job phases are `initialization` (profiling until step 0), `training_loop` (training and validation), and `finalization` (profiling after the hook is closed).

## Merge Timelines of Different Profiling Trace Files

The SMDebug client library provide profiling analysis and visualization tools for merging timelines of system metrics, framework metrics, and Python profiling data collected by Debugger.

### Tip

Before proceeding, you need to set a `TrainingJob` object that will be utilized throughout the examples in this page. For more information about setting up a `TrainingJob` object, see [Access the Monitoring and Profiling Data \(p. 1724\)](#).

The `MergedTimeline` class provides tools to integrate and correlate different profiling information in a single timeline. After Debugger captures profiling data and annotations from different phases of a training job, JSON files of trace events are saved in a default `tracefolder` directory.

- For annotations in the Python layers, the trace files are saved in `*pythontimeline.json`.
- For annotations in the TensorFlow C++ layers, the trace files are saved in `*model_timeline.json`.
- Tensorflow profiler saves events in a `*trace.json.gz` file.

### Tip

If you want to list all of the JSON trace files, use the following Amazon CLI command:

```
! aws s3 ls {tj.profiler_s3_output_path} --recursive | grep '\.json$'
```

As shown in the following animated screenshot, putting and aligning the trace events captured from the different profiling sources in a single plot can provide an overview of the entire events occurring in different phases of the training job.

### Tip

To interact with the merged timeline on the traicing app using a keyboard, use the **w** key for zooming in, the **A** key for shifting to the left, the **S** key for zooming out, and the **D** key for shifting to the right.

The multiple event trace JSON files can be merged into one trace event JSON file using the following `MergedTimeline` API operation and class method from the `smdebug.profiler.analysis.utils.merge_timelines` module.

```
from smdebug.profiler.analysis.utils.merge_timelines import MergedTimeline

combined_timeline = MergedTimeline(path, file_suffix_filter, output_directory)
combined_timeline.merge_timeline(start, end, unit)
```

The `MergedTimeline` API operation passes the following parameters:

- **path (str)** – Specify a root folder (`/profiler-output`) that contains system and framework profiling trace files. You can locate the `profiler-output` using the SageMaker estimator classmethod or the `TrainingJob` object. For example, `estimator.latest_job_profiler_artifacts_path()` or `tj.profiler_s3_output_path`.
- **file\_suffix\_filter (list)** – Specify a list of file suffix filters to merge timelines. Available suffix filters are `["model_timeline.json", "pythontimeline.json", "trace.json.gz"]`. If this parameter is not manually specified, all of the trace files are merged by default.
- **output\_directory (str)** – Specify a path to save the merged timeline JSON file. The default is to the directory specified for the `path` parameter.

The `merge_timeline()` classmethod passes the following parameters to execute the merging process:

- **start (int)** – Specify start time (in microseconds and in Unix time format) or start step to merge timelines.
- **end (int)** – Specify end time (in microseconds and in Unix time format) or end step to merge timelines.
- **unit (str)** – Choose between `"time"` and `"step"`. The default is `"time"`.

Using the following example codes, execute the `merge_timeline()` method and download the merged JSON file.

- Merge timeline with the `"time"` unit option. The following example code merges all available trace files between the Unix start time (the absolute zero Unix time) and the current Unix time, which means that you can merge the timelines for the entire training duration.

```
import time
from smdebug.profiler.analysis.utils.merge_timelines import MergedTimeline
from smdebug.profiler_constants import CONVERT_TO_MICROSECS

combined_timeline = MergedTimeline(tj.profiler_s3_output_path, output_directory="./")
combined_timeline.merge_timeline(0, int(time.time() * CONVERT_TO_MICROSECS))
```

- Merge timeline with the `"step"` unit option. The following example code merges all available timelines between step 3 and step 9.

```
from smdebug.profiler.analysis.utils.merge_timelines import MergedTimeline

combined_timeline = MergedTimeline(tj.profiler_s3_output_path, output_directory="./")
combined_timeline.merge_timeline(3, 9, unit="step")
```

Open the Chrome tracing app at <chrome://tracing> on a Chrome browser, and open the JSON file. You can explore the output to plot the merged timeline.

## Profiling Data Loader

In PyTorch, data loader iterators, such as `SingleProcessingDataLoaderIter` and `MultiProcessingDataLoaderIter`, are initiated at the beginning of every iteration over a dataset. During the initialization phase, PyTorch turns on worker processes depending on the configured number of workers, establishes data queue to fetch data and `pin_memory` threads.

To use the PyTorch data loader profiling analysis tool, import the following `PT_dataloader_analysis` class:

```
from smdebug.profiler.analysis.utils.pytorch_dataloader_analysis import  
PT_dataloader_analysis
```

Pass the profiling data retrieved as a Pandas frame data object in the [Access the Profiling Data Using the Pandas Data Parsing Tool \(p. 1726\)](#) section:

```
pt_analysis = PT_dataloader_analysis(pf)
```

The following functions are available for the `pt_analysis` object:

The `SMDebug S3SystemMetricsReader` class reads the system metrics from the S3 bucket specified to the `s3_trial_path` parameter.

- `pt_analysis.analyze_dataloaderIter_initialization()`

The analysis outputs the median and maximum duration for these initializations. If there are outliers, (i.e duration is greater than  $2 * \text{median}$ ), the function prints the start and end times for those durations. These can be used to inspect system metrics during those time intervals.

The following list shows what analysis is available from this class method:

- Which type of data loader iterators were initialized.
  - The number of workers per iterator.
  - Inspect whether the iterator was initialized with or without `pin_memory`.
  - Number of times the iterators were initialized during training.
- `pt_analysis.analyze_dataloaderWorkers()`

The following list shows what analysis is available from this class method:

- The number of worker processes that were spun off during the entire training.
- Median and maximum duration for the worker processes.
- Start and end time for the worker processes that are outliers.

- `pt_analysis.analyze_dataloader_getnext()`

The following list shows what analysis is available from this class method:

- Number of GetNext calls made during the training.
  - Median and maximum duration in microseconds for GetNext calls.
  - Start time, End time, duration and worker id for the outlier GetNext call duration.
- `pt_analysis.analyze_batchtime(start_timestamp, end_timestamp, select_events=['.*'], select_dimensions=['.*'])`

Debugger collects the start and end times of all the GetNext calls. You can find the amount of time spent by the training script on one batch of data. Within the specified time window, you can identify the calls that are not directly contributing to the training. These calls can be from the following

operations: computing the accuracy, adding the losses for debugging or logging purposes, and printing the debugging information. Operations like these can be compute intensive or time consuming. We can identify such operations by correlating the Python profiler, system metrics, and framework metrics.

The following list shows what analysis is available from this class method:

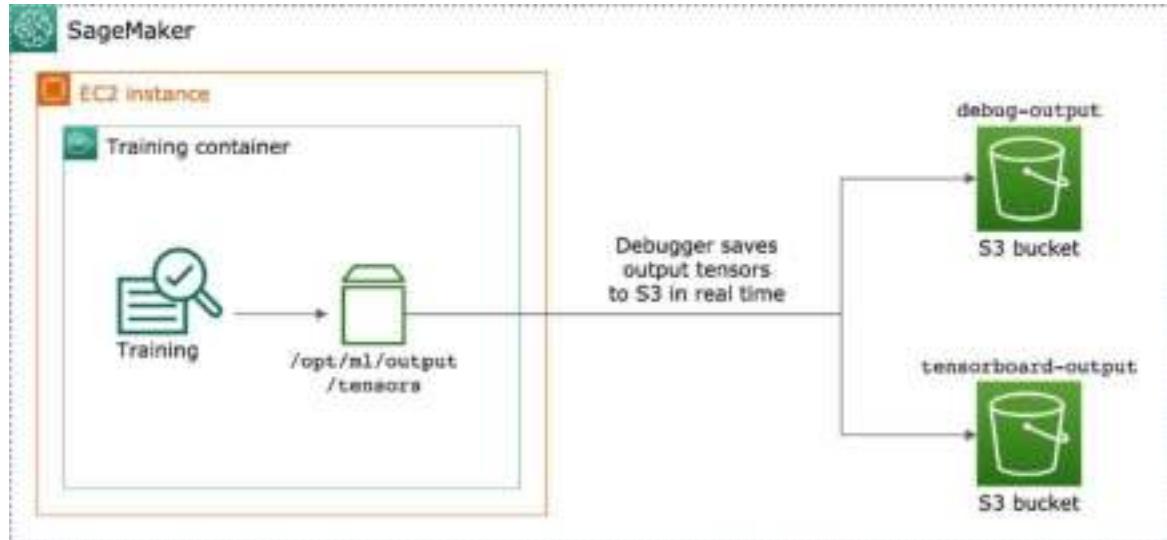

- Profile time spent on each data batch, `BatchTime_in_seconds`, by finding the difference between start times of current and subsequent `GetNext` calls.
- Find the outliers in `BatchTime_in_seconds` and start and end time for those outliers.
- Obtain the system and framework metrics during those `BatchTime_in_seconds` timestamps. This indicates where the time was spent.

• `pt_analysis.plot_the_window()`

Plots a timeline charts between a start timestamp and the end timestamp.

## Visualize Amazon SageMaker Debugger Output Tensors in TensorBoard

Use SageMaker Debugger to create output tensor files that are compatible with TensorBoard. Load the files to visualize in TensorBoard and analyze your SageMaker training jobs. Debugger automatically generates output tensor files that are compatible with TensorBoard. For any hook configuration you customize for saving output tensors, Debugger has the flexibility to create scalar summaries, distributions, and histograms that you can import to TensorBoard.

You can enable this by passing `DebuggerHookConfig` and `TensorBoardOutputConfig` objects to an estimator.

The following procedure explains how to save scalars, weights, and biases as full tensors, histograms, and distributions that can be visualized with TensorBoard. Debugger saves them to the training container's local path (the default path is `/opt/ml/output/tensors`) and syncs to the Amazon S3 locations passed through the Debugger output configuration objects.

### To save TensorBoard compatible output tensor files using Debugger

1. Set up a `tensorboard_output_config` configuration object to save TensorBoard output using the Debugger `TensorBoardOutputConfig` class. For the `s3_output_path` parameter, specify the

default S3 bucket of the current SageMaker session or a preferred S3 bucket. This example does not add the `container_local_output_path` parameter; instead, it is set to the default local path `/opt/ml/output/tensors`.

```
import sagemaker
from sagemaker.debugger import TensorBoardOutputConfig

bucket = sagemaker.Session().default_bucket()
tensorboard_output_config = TensorBoardOutputConfig(
    s3_output_path='s3://{}'.format(bucket)
)
```

For additional information, see the Debugger [TensorBoardOutputConfig](#) API in the [Amazon SageMaker Python SDK](#).

2. Configure the Debugger hook and customize the hook parameter values. For example, the following code configures a Debugger hook to save all scalar outputs every 100 steps in training phases and 10 steps in validation phases, the weights parameters every 500 steps (the default `save_interval` value for saving tensor collections is 500), and the biases parameters every 10 global steps until the global step reaches 500.

```
from sagemaker.debugger import CollectionConfig, DebuggerHookConfig

hook_config = DebuggerHookConfig(
    hook_parameters={
        "train.save_interval": "100",
        "eval.save_interval": "10"
    },
    collection_configs=[
        CollectionConfig("weights"),
        CollectionConfig(
            name="biases",
            parameters={
                "save_interval": "10",
                "end_step": "500",
                "save_histogram": "True"
            }
        ),
    ]
)
```

For more information about the Debugger configuration APIs, see the Debugger [CollectionConfig](#) and [DebuggerHookConfig](#) APIs in the [Amazon SageMaker Python SDK](#).

3. Construct a SageMaker estimator with the Debugger parameters passing the configuration objects. The following example template shows how to create a generic SageMaker estimator. You can replace `estimator` and `Estimator` with other SageMaker frameworks' estimator parent classes and estimator classes. Available SageMaker framework estimators for this functionality are [TensorFlow](#), [PyTorch](#), and [MXNet](#).

```
from sagemaker.estimator import Estimator

estimator = Estimator(
    ...
    # Debugger parameters
    debugger_hook_config=hook_config,
    tensorboard_output_config=tensorboard_output_config
)
estimator.fit()
```

The estimator.fit() method starts a training job, and Debugger writes the output tensor files in real time to the Debugger S3 output path and to the TensorBoard S3 output path. To retrieve the output paths, use the following estimator methods:

- For the Debugger S3 output path, use estimator.latest\_job\_debugger\_artifacts\_path().
  - For the TensorBoard S3 output path, use estimator.latest\_job\_tensorboard\_artifacts\_path().
4. After the training has completed, check the names of saved output tensors:

```
from smdebug.trials import create_trial
trial = create_trial(estimator.latest_job_debugger_artifacts_path())
trial.tensor_names()
```

5. Check the TensorBoard output data in Amazon S3:

```
tensorboard_output_path=estimator.latest_job_tensorboard_artifacts_path()
print(tensorboard_output_path)
!aws s3 ls {tensorboard_output_path}/
```

6. Download the TensorBoard output data to your notebook instance. For example, the following Amazon CLI command downloads the TensorBoard files to /logs/fit under the current working directory of your notebook instance.

```
!aws s3 cp --recursive {tensorboard_output_path} ./logs/fit
```

7. Compress the file directory to a TAR file to download to your local machine.

```
!tar -cf logs.tar logs
```

8. Download and extract the Tensorboard TAR file to a directory on your device, launch a Jupyter notebook server, open a new notebook, and run the TensorBoard app.

```
!tar -xf logs.tar
%load_ext tensorboard
%tensorboard --logdir logs/fit
```

## Best Practices for Amazon SageMaker Debugger

Use the following guidelines when you run training jobs with Debugger.

### Topics

- [Choose a Machine Learning Framework \(p. 1735\)](#)
- [Use Studio Debugger Insights Dashboard \(p. 1735\)](#)
- [Download Debugger Reports and Gain More Insights \(p. 1735\)](#)
- [Capture Data from Your Training Job and Save Data to Amazon S3 \(p. 1735\)](#)
- [Analyze the Data with a Fleet of Debugger Built-in Rules \(p. 1735\)](#)
- [Take Actions Based on the Built-in Rule Status \(p. 1735\)](#)
- [Dive Deep into the Data Using the SMDebug Client Library \(p. 1736\)](#)
- [Monitoring System Utilization and Detect Bottlenecks \(p. 1736\)](#)
- [Profiling Framework Operations \(p. 1736\)](#)

- [Debugging Model Parameters \(p. 1736\)](#)

## Choose a Machine Learning Framework

You can choose a machine learning framework and use SageMaker pre-built training containers or your own containers. Use Debugger to detect training and performance issues, and analyze training progress of your training job in SageMaker. SageMaker provides you options to use pre-built containers that are prepared for a number of machine learning framework environments to train your model on Amazon EC2. Any training job can be adapted to run in Amazon Deep Learning Containers, SageMaker training containers, and custom containers. To learn more, see [Configure Debugger Using Amazon SageMaker Python SDK \(p. 1593\)](#) and [Use Debugger with Custom Training Containers \(p. 1672\)](#).

## Use Studio Debugger Insights Dashboard

With Studio Debugger insights dashboard, you are in control of your training jobs. Use the Studio Debugger dashboards to keep your model performance on Amazon EC2 instances in control and optimized. For any SageMaker training jobs running on Amazon EC2 instance, Debugger monitors resource utilization and basic model output data (loss and accuracy values). Through the Studio Debugger dashboards, gain insights into your training jobs and improve your model training performance. To learn more, see [SageMaker Debugger on Studio \(p. 1685\)](#).

## Download Debugger Reports and Gain More Insights

You can view aggregated results and gain insights in Debugger reports. Debugger aggregates training and profiling results collected from the built-in rule analysis into a report per training job. You can find more detailed information about your training results through the Debugger reports. To learn more, see [SageMaker Debugger Interactive Reports \(p. 1700\)](#).

## Capture Data from Your Training Job and Save Data to Amazon S3

You can use a Debugger hook to save output tensors. After you choose a container and a framework that fit your training script, use a Debugger hook to configure which tensors to save and to which directory to save them, such as a Amazon S3 bucket. A Debugger hook helps you to build the configuration and to keep it in your account to use in subsequent analyses, where it is secured for use with the most privacy-sensitive applications. To learn more, see [Configure Debugger Hook to Save Tensors \(p. 1602\)](#).

## Analyze the Data with a Fleet of Debugger Built-in Rules

You can use Debugger built-in rules to inspect tensors in parallel with a training job. To analyze the training performance data, Debugger provides built-in rules that watch for abnormal training process behaviors. For example, a Debugger rule detects issues when the training process suffers from system bottleneck issues or training issues, such as vanishing gradients, exploding tensors, overfitting, or overtraining. If necessary, you can also build customized rules by creating a rule definition with your own criteria to define a training issue. To learn more about the Debugger rules, see [Configure Debugger Built-in Rules \(p. 1608\)](#) for detailed instructions of using the [Amazon SageMaker Python SDK](#). For a full list of the Debugger built-in rules, see [List of Debugger Built-in Rules \(p. 1626\)](#). If you want to create a custom rule, see [Create Debugger Custom Rules for Training Job Analysis \(p. 1670\)](#).

## Take Actions Based on the Built-in Rule Status

You can use Debugger with Amazon CloudWatch Events and Amazon Lambda. You can automate actions based on the rule status, such as stopping training jobs early and setting up notifications through email or text. When the Debugger rules detect problems and triggers an "IssuesFound" evaluation status,

CloudWatch Events detects the rule status changes and invokes the Lambda function to take actions. To configure automated actions to your training issues, see [Create Actions on Rules Using Amazon CloudWatch and Amazon Lambda \(p. 1680\)](#).

## Dive Deep into the Data Using the SMDebug Client Library

You can use the SMDebug tools to access and analyze training data collected by Debugger. The `TrainingJob` and `create_trial` classes load the metrics and tensors saved by Debugger. These classes provide extended class methods to analyze the data in real time or after the training has finished. The SMDebug library also provides visualization tools: merge timelines of framework metrics to aggregate different profiling, line charts and heatmap to track the system utilization, and histograms to find step duration outliers. To learn more about the SMDebug library tools, see [Analyze Data Using the SMDebug Client Library \(p. 1724\)](#).

## Monitoring System Utilization and Detect Bottlenecks

With Amazon SageMaker Debugger monitoring, you can measure hardware system resource utilization of Amazon EC2 instances. Monitoring is available for any SageMaker training job constructed with the SageMaker framework estimators (TensorFlow, PyTorch, and MXNet) and the generic SageMaker estimator (SageMaker built-in algorithms and your own custom containers). Debugger built-in rules for monitoring detect system bottleneck issues and notify you when they detect the bottleneck issues.

To learn how to enable Debugger system monitoring, see [Configure Debugger Using Amazon SageMaker Python SDK \(p. 1593\)](#) and then [Configure Debugger Monitoring Hardware System Resource Utilization \(p. 1598\)](#).

For a full list of available built-in rules for monitoring, see [Debugger Built-in Rules for Monitoring Hardware System Resource Utilization \(System Metrics\) \(p. 1626\)](#).

## Profiling Framework Operations

With Amazon SageMaker Debugger profiling you can profile deep learning frameworks operations. You can profile your model training with the SageMaker TensorFlow training containers, the SageMaker PyTorch framework containers, and your own training containers. Using the profiling feature of Debugger, you can drill down into the Python operators and functions that are executed to perform the training job. Debugger supports detailed profiling, Python profiling, data loader profiling, and Horovod distributed training profiling. You can merge the profiled timelines to correlate with the system bottlenecks. Debugger built-in rules for profiling watch framework operation related issues, including excessive training initialization time due to data downloading before training starts and step duration outliers in training loops.

To learn how to configure Debugger for framework profiling, see [Configure Debugger Using Amazon SageMaker Python SDK \(p. 1593\)](#) and then [Configure Debugger Framework Profiling \(p. 1598\)](#).

For a complete list of available built-in rules for profiling, see [Debugger Built-in Rules for Profiling Framework Metrics \(p. 1626\)](#).

## Debugging Model Parameters

Debugging is available for deep learning frameworks using Amazon Deep Learning Containers and the SageMaker training containers. For fully supported framework versions (see the versions at [Supported Frameworks and Algorithms \(p. 1581\)](#)), Debugger automatically registers hooks to collect output tensors, and you can directly run your training script. For the versions with one asterisk sign, you need to manually register the hooks to collect tensors. Debugger provides preconfigured tensor collections with generalized names that you can utilize across the different frameworks. If you want to customize output tensor configuration, you can also use the `CollectionConfig` and `DebuggerHookConfig` API operations and the [Amazon SageMaker Python SDK](#) to configure your own tensor collections. Debugger built-in rules

for debugging analyze the output tensors and identifies model optimization problems that blocks your model from minimizing the loss function. For example, the rules identify overfitting, overtraining, loss not decreasing, exploding tensors, and vanishing gradients.

To learn how to configure Debugger for debugging output tensors, see [Configure Debugger Using Amazon SageMaker Python SDK \(p. 1593\)](#) and then [Configure Debugger Hook to Save Tensors \(p. 1602\)](#).

For a full list of available built-in rules for debugging, see [Debugger Built-in Rules for Debugging Model Training Data \(Output Tensors\) \(p. 1627\)](#).

## Amazon SageMaker Debugger Advanced Topics and Reference Documentation

The following sections contain advanced topics, reference documentation for the API operations, exceptions, and known limitations for Debugger.

### Topics

- [Amazon SageMaker Debugger API Operations \(p. 1737\)](#)
- [Use Debugger Docker Images for Built-in or Custom Rules \(p. 1738\)](#)
- [Amazon SageMaker Debugger Exceptions \(p. 1740\)](#)
- [Considerations for Amazon SageMaker Debugger \(p. 1741\)](#)
- [Amazon SageMaker Debugger Usage Statistics \(p. 1743\)](#)

## Amazon SageMaker Debugger API Operations

Amazon SageMaker Debugger has API operations in several locations that are used to implement its monitoring and analysis of model training.

Amazon SageMaker Debugger also provides the open source SMDebug Python library at [awslabs/sagemaker-debugger](#) that is used to configure built-in rules, define custom rules, and register hooks to collect output tensor data from training jobs.

The [Amazon SageMaker Python SDK](#) is a high-level SDK focused on machine learning experimentation. The SDK can be used to deploy built-in or custom rules defined with the SMDebug Python library to monitor and analyze these tensors using SageMaker estimators.

Debugger has added operations and types to the Amazon SageMaker API that enable the platform to use Debugger when training a model and to manage the configuration of inputs and outputs.

- `CreateTrainingJob` and `UpdateTrainingJob` use the following Debugger APIs to configure tensor collections, rules, rule images, and profiling options:
  - `CollectionConfiguration`
  - `DebugHookConfig`
  - `DebugRuleConfiguration`
  - `TensorBoardOutputConfig`
  - `ProfilerConfig`
  - `ProfilerRuleConfiguration`
- `DescribeTrainingJob` provides a full description of a training job, including the following Debugger configurations and rule evaluation statuses:
  - `DebugHookConfig`
  - `DebugRuleConfiguration`
  - `DebugRuleEvaluationStatus`

- [ProfilerConfig](#)
- [ProfilerRuleConfiguration](#)
- [ProfilerRuleEvaluationStatus](#)

The rule configuration API operations use the SageMaker Processing functionality when analyzing a model training. For more information about SageMaker Processing, see [Process Data \(p. 664\)](#).

## Use Debugger Docker Images for Built-in or Custom Rules

Amazon SageMaker provides two sets of Docker images for rules: one set for evaluating rules provided by SageMaker (built-in rules) and one set for evaluating custom rules provided in Python source files.

If you use the [Amazon SageMaker Python SDK](#), you can simply use SageMaker high-level Debugger API operations with SageMaker Estimator API operations, without having to manually retrieve the Debugger Docker images and configure the `ConfigureTrainingJobAPI`.

If you are not using the SageMaker Python SDK, you have to retrieve a relevant pre-built container base image for the Debugger rules. Amazon SageMaker Debugger provides pre-built Docker images for built-in and custom rules, and the images are stored in Amazon Elastic Container Registry (Amazon ECR). To pull an image from an Amazon ECR repository (or to push an image to one), use the full name registry URL of the image using the `CreateTrainingJob` API. SageMaker uses the following URL patterns for the Debugger rule container image registry address.

```
<account_id>.dkr.ecr.<Region>.amazonaws.com/<ECR repository name>:<tag>
```

For the account ID in each Amazon Region, Amazon ECR repository name, and tag value, see the following topics.

### Topics

- [Amazon SageMaker Debugger Registry URLs for Built-in Rule Evaluators \(p. 1738\)](#)
- [Amazon SageMaker Debugger Registry URLs for Custom Rule Evaluators \(p. 1739\)](#)

## Amazon SageMaker Debugger Registry URLs for Built-in Rule Evaluators

Use the following values for the components of the registry URLs for the images that provide built-in rules for Amazon SageMaker Debugger. For account IDs, see the following table.

**ECR Repository Name:** sagemaker-debugger-rules

**Tag:** latest

**Example of a full registry URL:**

```
904829902805.dkr.ecr.ap-south-1.amazonaws.com/sagemaker-debugger-rules:latest
```

### Account IDs for Built-in Rules Container Images by Amazon Region

Region	account_id
af-south-1	314341159256
ap-east-1	199566480951
ap-northeast-1	430734990657
ap-northeast-2	578805364391

Region	account_id
ap-south-1	904829902805
ap-southeast-1	972752614525
ap-southeast-2	184798709955
ca-central-1	519511493484

## Amazon SageMaker Debugger Exceptions

Amazon SageMaker Debugger is designed to be aware that tensors required to execute a rule might not be available at every step. As a result, it raises a few exceptions, which enable you to control what happens when a tensor is missing. These exceptions are available in the [smdebug.exceptions module](#). You can import them as follows:

```
from smdebug.exceptions import *
```

The following exceptions are available:

- **TensorUnavailableForStep** – The tensor requested is not available for the step. This might mean that this step might not be saved at all by the hook, or that this step might have saved some tensors but the requested tensor is not part of them. Note that when you see this exception, it means that this tensor can never become available for this step in the future. If the tensor has reductions saved for the step, it notifies you they can be queried.

- `TensorUnavailable` – This tensor is not being saved or has not been saved by the `smdebug` API. This means that this tensor is never seen for any step in `smdebug`.
- `StepUnavailable` – The step was not saved and Debugger has no data from the step.
- `StepNotYetAvailable` – The step has not yet been seen by `smdebug`. It might be available in the future if the training is still going on. Debugger automatically loads new data as it becomes available.
- `NoMoreData` – Raised when the training ends. Once you see this, you know that there are no more steps and no more tensors to be saved.
- `IndexReaderException` – The index reader is not valid.
- `InvalidWorker` – A worker was invoked that was not valid.
- `RuleEvaluationConditionMet` – Evaluation of the rule at the step resulted in the condition being met.
- `InsufficientInformationForRuleInvocation` – Insufficient information was provided to invoke the rule.

## Considerations for Amazon SageMaker Debugger

Consider the following when using Amazon SageMaker Debugger.

### Considerations for Distributed Training

The following list shows the scope of validity and considerations for using Debugger on training jobs with deep learning frameworks and various distributed training options.

- **Horovod**

#### Scope of validity of using Debugger for training jobs with Horovod

Deep Learning Framework	Apache MXNet	TensorFlow 1.x	TensorFlow 2.x	TensorFlow 2.x with Keras	PyTorch
Monitoring system bottlenecks	Yes	Yes	Yes	Yes	Yes
Profiling framework operations	No	No	No	Yes	Yes
Debugging model output tensors	Yes	Yes	Yes	Yes	Yes

- **SageMaker distributed data parallel**

#### Scope of validity of using Debugger for training jobs with SageMaker distributed data parallel

Deep Learning Framework	TensorFlow 2.x	TensorFlow 2.x with Keras	PyTorch
Monitoring system bottlenecks	Yes	Yes	Yes
Profiling framework operations	No*	No**	Yes

Deep Learning Framework	TensorFlow 2.x	TensorFlow 2.x with Keras	PyTorch
Debugging model output tensors	Yes	Yes	Yes

\* Debugger does not support framework profiling for TensorFlow 2.x.

\*\* SageMaker distributed data parallel does not support TensorFlow 2.x with Keras implementation.

- **SageMaker distributed model parallel** – Debugger does not support SageMaker distributed model parallel training.
- **Distributed training with SageMaker checkpoints** – Debugger is not available for training jobs when both the distributed training option and SageMaker checkpoints are enabled. You might see an error that looks like the following:

```
SMDebug Does Not Currently Support Distributed Training Jobs With Checkpointing Enabled
```

To use Debugger for training jobs with distributed training options, you need to disable SageMaker checkpointing and add manual checkpointing functions to your training script. For more information about using Debugger with distributed training options and checkpoints, see [Considerations for Using SageMaker Distributed Data Parallel with SageMaker Debugger and Checkpoints \(p. 1794\)](#) and [Saving Checkpoints \(p. 1818\)](#).

- **Parameter Server** – Debugger does not support parameter server-based distributed training.
- Profiling distributed training framework operations, such as the `AllReduced` operation of SageMaker distributed data parallel and [Horovod operations](#), is not available.

## Considerations for Monitoring System Bottlenecks and Profiling Framework Operations

- For Amazon TensorFlow, data loader metrics cannot be collected using the default `local_path` setting of the `FrameworkProfile` class. The path has to be manually configured and end in `"/"`. For example:

```
FrameworkProfile(local_path="/opt/ml/output/profiler/")
```

- For Amazon TensorFlow, the data loader profiling configuration cannot be updated while a training job is running.
- For Amazon TensorFlow, a `NoneType` error might occur when you use analysis tools and notebook examples with TensorFlow 2.3 training jobs and the detailed profiling option.
- Python profiling and detailed profiling are only supported for Keras API.
- To access the deep profiling feature for TensorFlow and PyTorch, currently you must specify the latest Amazon deep learning container images with CUDA 11. For example, you must specify the specific image URI in the TensorFlow and PyTorch estimator as follows:

- For TensorFlow

```
image_uri = f"763104351884.dkr.ecr.{region}.amazonaws.com/tensorflow-training:2.3.1-gpu-py37-cu110-ubuntu18.04"
```

- For PyTorch

```
image_uri = f"763104351884.dkr.ecr.{region}.amazonaws.com/pytorch-training:1.6.0-gpu-py36-cu110-ubuntu18.04"
```

## Considerations for Debugging Model Output Tensors

- Avoid using functional API operations. Debugger cannot collect model output tensors from PyTorch and MXNet training scripts composed of functional API operations.
- Debugger cannot collect model output tensors from the `torch.nn.functional` API operations. When you write a PyTorch training script, it is recommended to use the `torch.nn` modules instead.
- Debugger cannot collect model output tensors from MXNet functional objects in hybrid blocks. For example, the ReLU activation (`F.relu`) outputs cannot be collected from the following example of `mxnet.gluon.HybridBlock` with `F` in the `hybrid_forward` function.

```
import mxnet as mx
from mxnet.gluon import HybridBlock, nn

class Model(HybridBlock):
    def __init__(self, **kwargs):
        super(Model, self).__init__(**kwargs)
        # use name_scope to give child Blocks appropriate names.
        with self.name_scope():
            self.dense0 = nn.Dense(20)
            self.dense1 = nn.Dense(20)

    def hybrid_forward(self, F, x):
        x = F.relu(self.dense0(x))
        return F.relu(self.dense1(x))

model = Model()
model.initialize(ctx=mx.cpu(0))
model.hybridize()
model(mx.nd.zeros((10, 10), ctx=mx.cpu(0)))
```

## Amazon SageMaker Debugger Usage Statistics

Consider the following when using autogenerated reports by Amazon SageMaker Debugger.

### Debugger Profiling Report Usage

For all SageMaker training jobs, Amazon SageMaker Debugger runs the [ProfilerReport \(p. 1628\)](#) rule and autogenerates a [SageMaker Debugger Profiling Report \(p. 1701\)](#). The `ProfilerReport` rule provides a Jupyter notebook file (`profiler-report.ipynb`) that generates a corresponding HTML file (`profiler-report.html`).

Debugger collects profiling report usage statistics by including code in the Jupyter notebook that collects the unique `ProfilerReport` rule's processing job ARN if the user opens the final `profiler-report.html` file.

Debugger only collects information about whether a user opens the final HTML report. It **DOES NOT** collect any information from training jobs, training data, training scripts, processing jobs, logs, or the content of the profiling report itself.

You can opt out of the collection of usage statistics using either of the following options.

#### (Recommended) Option 1: Opt Out before Running a Training Job

To opt out, you need to add the following Debugger `ProfilerReport` rule configuration to your training job request.

SageMaker Python SDK

```
estimator=sagemaker.estimator.Estimator(
```

```
    ...
    rules=ProfilerRule.sagemaker(
        base_config=rule_configs.ProfilerReport()
        rule_parameters={"opt_out_telemetry": "True"}
    )
}
```

### Amazon CLI

```
"ProfilerRuleConfigurations": [
    {
        "RuleConfigurationName": "ProfilerReport-1234567890",
        "RuleEvaluatorImage": "895741380848.dkr.ecr.us-west-2.amazonaws.com/sagemaker-
debugger-rules:latest",
        "RuleParameters": {
            "rule_to_invoke": "ProfilerReport",
            "opt_out_telemetry": "True"
        }
    }
]
```

### Amazon SDK for Python (Boto3)

```
ProfilerRuleConfigurations=[
    {
        'RuleConfigurationName': 'ProfilerReport-1234567890',
        'RuleEvaluatorImage': '895741380848.dkr.ecr.us-west-2.amazonaws.com/sagemaker-
debugger-rules:latest',
        'RuleParameters': {
            'rule_to_invoke': 'ProfilerReport',
            'opt_out_telemetry': 'True'
        }
    }
]
```

## Option 2: Opt Out after a Training Job Has Completed

To opt out after training has completed, you need to modify the `profiler-report.ipynb` file.

### Note

HTML reports autogenerated without **Option 1** already added to your training job request still report the usage statistics even after you opt out using **Option 2**.

1. Follow the instructions on downloading the Debugger profiling report files in the [Download a Debugger Profiling Report \(p. 1701\)](#) page.
2. In the `/ProfilerReport-1234567890/profiler-output` directory, open `profiler-report.ipynb`.
3. Add `opt_out=True` to the `setup_profiler_report()` function in the fifth code cell as shown in the following example code:

```
setup_profiler_report(processing_job_arn, opt_out=True)
```

4. Run the code cell to finish opting out.

# Perform Automatic Model Tuning with SageMaker

Amazon SageMaker automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many training jobs on your dataset using the algorithm and ranges of hyperparameters that you specify. It then chooses the hyperparameter values that result in a model that performs the best, as measured by a metric that you choose.

For example, suppose that you want to solve a [binary classification](#) problem on a marketing dataset. Your goal is to maximize the [area under the curve \(auc\)](#) metric of the algorithm by training an [XGBoost Algorithm \(p. 1524\)](#) model. You don't know which values of the `eta`, `alpha`, `min_child_weight`, and `max_depth` hyperparameters to use to train the best model. To find the best values for these hyperparameters, you can specify ranges of values that SageMaker hyperparameter tuning searches to find the combination of values that results in the training job that performs the best as measured by the objective metric that you chose. Hyperparameter tuning launches training jobs that use hyperparameter values in the ranges that you specified, and returns the training job with highest auc.

You can use SageMaker automatic model tuning with built-in algorithms, custom algorithms, and SageMaker pre-built containers for machine learning frameworks.

Amazon SageMaker automatic model tuning can use Amazon EC2 Spot instance to optimize costs when running training jobs. For more information on managed spot training, see [Managed Spot Training in Amazon SageMaker \(p. 1859\)](#).

Before you start using hyperparameter tuning, you should have a well-defined machine learning problem, including the following:

- A dataset
- An understanding of the type of algorithm you need to train
- A clear understanding of how you measure success

You should also prepare your dataset and algorithm so that they work in SageMaker and successfully run a training job at least once. For information about setting up and running a training job, see [Get Started with Amazon SageMaker \(p. 34\)](#).

## How Hyperparameter Tuning Works

### Random Search

In a random search, hyperparameter tuning chooses a random combination of values from within the ranges that you specify for hyperparameters for each training job it launches. Because the choice of hyperparameter values doesn't depend on the results of previous training jobs, you can run the maximum number of concurrent training jobs without affecting the performance of the search.

For an example notebook that uses random search, see [https://github.com/awslabs/amazon-sagemaker-examples/blob/master/hyperparameter\\_tuning/xgboost\\_random\\_log/hpo\\_xgboost\\_random\\_log.ipynb](https://github.com/awslabs/amazon-sagemaker-examples/blob/master/hyperparameter_tuning/xgboost_random_log/hpo_xgboost_random_log.ipynb).

## Bayesian Search

Bayesian search treats hyperparameter tuning like a [\[regression\]](#) problem. Given a set of input features (the hyperparameters), hyperparameter tuning optimizes a model for the metric that you choose. To solve a regression problem, hyperparameter tuning makes guesses about which hyperparameter combinations are likely to get the best results, and runs training jobs to test these values. After testing the first set of hyperparameter values, hyperparameter tuning uses regression to choose the next set of hyperparameter values to test.

Hyperparameter tuning uses a Amazon SageMaker implementation of Bayesian optimization.

When choosing the best hyperparameters for the next training job, hyperparameter tuning considers everything that it knows about this problem so far. Sometimes it chooses a combination of hyperparameter values close to the combination that resulted in the best previous training job to incrementally improve performance. This allows hyperparameter tuning to exploit the best known results. Other times, it chooses a set of hyperparameter values far removed from those it has tried. This allows it to explore the range of hyperparameter values to try to find new areas that are not well understood. The explore/exploit trade-off is common in many machine learning problems.

#### Note

Hyperparameter tuning might not improve your model. It is an advanced tool for building machine solutions, and, as such, should be considered part of the scientific development process.

When you build complex machine learning systems like deep learning neural networks, exploring all of the possible combinations is impractical. Hyperparameter tuning can accelerate

your productivity by trying many variations of a model, focusing on the most promising combinations of hyperparameter values within the ranges that you specify. To get good results, you need to choose the right ranges to explore. Because the algorithm itself is stochastic, it's possible that the hyperparameter tuning model will fail to converge on the best answer, even if the best possible combination of values is within the ranges that you choose.

## Define Metrics

When you use one of the Amazon SageMaker built-in algorithms, you don't need to define metrics. Built-in algorithms automatically send metrics to hyperparameter tuning. You do need to choose one of the metrics that the built-in algorithm emits as the objective metric for the tuning job. For a list of metrics that a built-in algorithm emits, see the *Metrics* table for the algorithm in [Use Amazon SageMaker Built-in Algorithms \(p. 718\)](#).

To optimize hyperparameters for a machine learning model, a tuning job evaluates the training jobs it launches by using a metric that the training algorithm writes to logs. Amazon SageMaker hyperparameter tuning parses your algorithm's `stdout` and `stderr` streams to find algorithm metrics, such as loss or validation-accuracy, that show how well the model is performing on the dataset.

**Note**

These are the same metrics that SageMaker sends to CloudWatch Logs. For more information, see [Log Amazon SageMaker Events with Amazon CloudWatch \(p. 2534\)](#).

If you use your own algorithm for hyperparameter tuning, make sure that your algorithm emits at least one metric by writing evaluation data to `stderr` or `stdout`.

**Note**

Hyperparameter tuning sends an additional hyperparameter, `_tuning_objective_metric` to the training algorithm. This hyperparameter specifies the objective metric being used for the hyperparameter tuning job, so that your algorithm can use that information during training.

You can define up to 20 metrics for your tuning job to monitor. You choose one of those metrics to be the objective metric, which hyperparameter tuning uses to evaluate the training jobs. The hyperparameter tuning job returns the training job that returned the best value for the objective metric as the best training job.

You define metrics for a tuning job by specifying a name and a regular expression for each metric that your tuning job monitors. Design the regular expressions to capture the values of metrics that your algorithm emits. You pass these metrics to the `CreateHyperParameterTuningJob` operation in the `TrainingJobDefinition` parameter as the `MetricDefinitions` field of the `AlgorithmSpecification` field.

The following example defines 4 metrics:

```
=[
  {
    "Name": "loss",
    "Regex": "Loss = (.*) ;",
  },
  {
    "Name": "ganloss",
    "Regex": "GAN_loss=(.*?);",
  },
  {
    "Name": "discloss",
    "Regex": "disc_train_loss=(.*?);",
  },
  {
    "Name": "disc-combined",
    "Regex": "disc-combined=(.*?);",
  },
]
```

]

The following is an example of the log that the algorithm writes:

```
GAN_loss=0.138318; Scaled_reg=2.654134; disc:[-0.017371,0.102429] real 93.3% gen 0.0%
disc-combined=0.000000; disc_train_loss=1.374587; Loss = 16.020744; Iteration 0 took
0.704s; Elapsed=0s
```

Use the regular expression (regex) to match the algorithm's log output and capture the numeric values of metrics. For example, in the regex for the loss metric defined above, the first part of the regex finds the exact text "Loss = ", and the expression `(.*?)`; captures zero or more of any character until the first semicolon character. In this expression, the parenthesis tell the regex to capture what is inside them, `.` means any character, `*` means zero or more, and `?` means capture only until the first instance of the `;` character.

Choose one of the metrics that you define as the objective metric for the tuning job. If you are using the API, specify the value of the `name` key in the `HyperParameterTuningJobObjective` field of the `HyperParameterTuningJobConfig` parameter that you send to the [CreateHyperParameterTuningJob](#) operation.

## Define Hyperparameter Ranges

Hyperparameter tuning finds the best hyperparameter values for your model by searching over a set of values that you specify for each of the hyperparameters that are tunable. Choosing hyperparameters and ranges significantly affects the performance of your tuning job. For guidance on choosing hyperparameters and ranges, see [Best Practices for Hyperparameter Tuning \(p. 1770\)](#).

To define hyperparameter ranges by using the low-level API, you specify the names of hyperparameters and ranges of values in the `ParameterRanges` field of the `HyperParameterTuningJobConfig` parameter that you pass to the [CreateHyperParameterTuningJob](#) operation. The `ParameterRanges` field has three subfields, one for each of the categorical, integer, and continuous hyperparameter ranges. You can define up to 20 hyperparameters to search over. Each value of a categorical hyperparameter range counts as a hyperparameter against the limit. Hyperparameter ranges have the following structure:

```
"ParameterRanges": {
    "CategoricalParameterRanges": [
        {
            "Name": "tree_method",
            "Values": ["auto", "exact", "approx", "hist"]
        }
    ],
    "ContinuousParameterRanges": [
        {
            "Name": "eta",
            "MaxValue": "0.5",
            "MinValue": "0",
            "ScalingType": "Auto"
        }
    ],
    "IntegerParameterRanges": [
        {
            "Name": "max_depth",
            "MaxValue": "10",
            "MinValue": "1",
            "ScalingType": "Auto"
        }
    ]
}
```

## Hyperparameter Scaling

For integer and continuous hyperparameter ranges, you can choose the scale you want hyperparameter tuning to use to search the range of values by specifying a value for the `ScalingType` field of the hyperparameter range. You can choose from the following scaling types:

### Auto

SageMaker hyperparameter tuning chooses the best scale for the hyperparameter.

### Linear

Hyperparameter tuning searches the values in the hyperparameter range by using a linear scale. Typically, you choose this if the range of all values from the lowest to the highest is relatively small (within one order of magnitude), because uniformly searching values from the range will give you a reasonable exploration of the entire range.

### Logarithmic

Hyperparameter tuning searches the values in the hyperparameter range by using a logarithmic scale.

Logarithmic scaling works only for ranges that have only values greater than 0.

Choose logarithmic scaling when you are searching a range that spans several orders of magnitude. For example, if you are tuning a [Tune a linear learner model \(p. 1442\)](#) model, and you specify a range of values between .0001 and 1.0 for the `learning_rate` hyperparameter, searching uniformly on a logarithmic scale gives you a better sample of the entire range than searching on a linear scale would, because searching on a linear scale would, on average, devote 90 percent of your training budget to only the values between .1 and 1.0, leaving only 10 percent of your training budget for the values between .0001 and .1.

### ReverseLogarithmic

Hyperparameter tuning searches the values in the hyperparameter range by using a reverse logarithmic scale. reverse logarithmic scaling is supported only for continuous hyperparameter ranges. It is not supported for integer hyperparameter ranges.

Reverse logarithmic scaling works only for ranges that are entirely within the range  $0 \leq x < 1.0$ .

Choose reverse logarithmic scaling when you are searching a range that is highly sensitive to small changes that are very close to 1.

For an example notebook that uses hyperparameter scaling, see [https://github.com/awslabs/amazon-sagemaker-examples/blob/master/hyperparameter\\_tuning/xgboost\\_random\\_log/hpo\\_xgboost\\_random\\_log.ipynb](https://github.com/awslabs/amazon-sagemaker-examples/blob/master/hyperparameter_tuning/xgboost_random_log/hpo_xgboost_random_log.ipynb).

## Tune Multiple Algorithms with Hyperparameter Optimization to Find the Best Model

To create a new hyperparameter optimization (HPO) job with Amazon SageMaker that tunes multiple algorithms, you must provide job settings that apply to all of the algorithms to be tested and a training definition for each of these algorithms. You must also specify the resources you want to use for the tuning job.

- The **job settings** to configure include warm starting, early stopping, and the tuning strategy. Warm starting and early stopping are available only when tuning a single algorithm.
- The **training job definition** to specify the name, algorithm source, objective metric, and the range of values, when required, to configure the set of hyperparameter values for each training job. It

configures the channels for data inputs, data output locations, and any checkpoint storage locations for each training job. The definition also configures the resources to deploy for each training job, including instance types and counts, managed spot training, and stopping conditions.

- The **tuning job resources**: to deploy, including the maximum number of concurrent training jobs that a hyperparameter tuning job can run concurrently and the maximum number of training jobs that the hyperparameter tuning job can run.

## Get Started

You can create a new hyperparameter tuning job, clone a job, add or edit tags to a job from the console. You can also use the search feature to find jobs by their name, creation time, or status. Alternatively, you can also hyperparameter tuning jobs with the SageMaker API.

- **In the console:** To create a new job, open the Amazon SageMaker console at <https://console.amazonaws.cn/sagemaker/>, choose **Hyperparameter tuning jobs** from the **Training**, menu, and then choose **Create hyperparameter tuning job**. Then following the configuration steps to create a training job for each algorithm that you want to use. These steps are documented in the [Create a Hyperparameter Optimization Tuning Job for One or More Algorithms \(Console\) \(p. 1750\)](#) topic.

### Note

When you start the configuration steps, note that the warm start and early stopping features are not available to use with multi-algorithm HPO. If you want to use these features, you can only tune a single algorithm at a time.

- **With the API:** For instructions on using the SageMaker API to create a hyperparameter tuning job, see [Example: Hyperparameter Tuning Job](#). When you call `CreateHyperParameterTuningJob` to tune multiple algorithms, you must provide a list of training definitions using `TrainingJobDefinitions` instead of specifying a single `TrainingJobDefinition`. You must choose just one of these definition types depending on the number of algorithms being tuned.

### Topics

- [Create a Hyperparameter Optimization Tuning Job for One or More Algorithms \(Console\) \(p. 1750\)](#)
- [Manage Hyperparameter Tuning and Training Jobs \(p. 1754\)](#)

## Create a Hyperparameter Optimization Tuning Job for One or More Algorithms (Console)

To create a new hyperparameter optimization (HPO) tuning job for one or more algorithms, you need to define the settings for the tuning job, create training job definitions for each algorithm being tuned, and configure the resources for the tuning job.

### Topics

- [Define job settings \(p. 1750\)](#)
- [Create Training Job Definitions \(p. 1751\)](#)
- [Configure Tuning Job Resources \(p. 1753\)](#)
- [Review and Create HPO Tuning Job \(p. 1753\)](#)

## Define job settings

Your tuning job settings are applied across all of the algorithms in the HPO tuning job. Warm start and early stopping are available only when tuning a single algorithm. After you define the job settings you will create individual training definitions for each algorithm or variation you want to tune.

## Warm Start

If you cloned this job, you can choose to use the results from a previous tuning job to improve the performance of this new tuning job. This is the warm start feature and it is only available when tuning a single algorithm. When you choose this option, you can choose up to five previous hyperparameter tuning jobs to use. Alternatively, you can use transfer learning to add additional data to the parent tuning job. When you select this option, you choose one previous tuning job as the parent.

### Note

Warm start is compatible only with tuning jobs created after October 1, 2018. For more information, see [Run a warm start job](#).

## Early Stopping

To reduce compute time and avoid overfitting your model, training jobs can be stopped early when they are unlikely to improve the current best objective metric of the hyperparameter tuning job.. Like warm start, this feature is only available when tuning a single algorithm. This is an automatic feature without configuration options, and it's disabled by default. For more information on how early stopping works, the algorithms that support it, and how to use it with your own algorithms, see [Stop Training Jobs Early](#).

## Tuning Strategy

Tuning strategy can be either random or Bayesian. It specifies how the automatic tuning searches over specified hyperparameter ranges. You specify the ranges in a later step. Random search chooses random combinations of values from the specified ranges and can be run concurrently. Bayesian search chooses values based on what is likely to get the best result given what is known about the history of previous selections. For more information search strategies, see [How Hyperparameter Tuning Works](#).

## Tags

You enter tags as key-value pairs to assign metadata to tuning jobs to help you manage them. Values are not required. You can use just the key. To see the keys associated with a job, choose the **Tags** tab on the details page for tuning job. For more information about using tags for tuning jobs, see [Manage Hyperparameter Tuning and Training Jobs \(p. 1754\)](#)

## Create Training Job Definitions

To create a training job definition, you need to configure the algorithm and parameters, define the data input and output, and configure resources. You must provide at least one [TrainingJobDefinition](#) for each HPO tuning job. Each training definition specifies the configuration for an algorithm. To create several definitions for your training job you can clone a job definition. Cloning a job can save time as it copies all of the job settings, including data channels, S3 storage locations for output artifacts. You can then edit the cloned job just for changes needed to configure the algorithm options.

### Topics

- [Configure algorithm and parameters \(p. 1751\)](#)
- [Define Data Input and Output \(p. 1752\)](#)
- [Configure Training Job Resources \(p. 1753\)](#)
- [Add or Clone a Training Job \(p. 1753\)](#)

## Configure algorithm and parameters

Each training job definition for a tuning job requires a name, permission to access services, and the specification of algorithm options, an objective metric, and the range of values, when required, to configure the set of hyperparameter values for each training job.

### Name

Provide a unique name for the training definition.

### Permissions

Amazon SageMaker requires permissions to call other services on your behalf. Choose an IAM role or let Amazon create a role that has the `AmazonSageMakerFullAccess` IAM policy attached.

### Optional Security Settings

The network isolation setting prevents the container from making any outbound network calls. This is required for Amazon Marketplace machine learning offerings.

You can also choose to use a private VPC.

#### Note

Inter-container encryption is only available when creating job definitions from the API.

### Algorithm Options

You can choose one of the built-in algorithms, your own algorithm, your own container with an algorithm, or you can subscribe to an algorithm from Amazon Marketplace.

- If you choose a built-in algorithm, it has the ECR image information prepopulated.
- If you choose your own container, you must specify the ECR image information. You can select the input mode for the algorithm as file or pipe.
- If you plan to supply your data using a .CSV file from Amazon S3, you should select the file.

### Metrics

When you choose a built-in algorithm, metrics are provided for you. If you choose your own algorithm, you need to define your metrics. You can define up to 20 metrics for your tuning job to monitor, one of which must be chosen as the objective metric. For more information on how to define a metric for a tuning job, see [Define Metrics \(p. 1747\)](#).

### Objective Metric

To find the best training job, set an objective metric and whether to maximize or minimize it. After the training job is complete, you can view the tuning job detail page for a summary of the best training job found using this objective metric.

### Hyperparameter Configuration

When you choose a built-in algorithm, the default values for its hyperparameters are set for you, using ranges that are optimized for the algorithm being tuned. You can change these values as you see fit. For example, instead of a range, you can set a fixed value for a hyperparameter by setting the parameter's type to `static`. Each algorithm has different required and optional parameters. For more information, see [Best Practices for Hyperparameter Tuning](#) and [Define Hyperparameter Ranges](#).

### Define Data Input and Output

Each training job definition for a tuning job must configures the channels for data inputs, data output locations, and optionally any checkpoint storage locations for each training job.

### Input Data Configuration

Input data is defined by channels, each with their own source location (Amazon S3 or Amazon Elastic File System), compression, and format options. You can define up to 20 channels of input sources. If the

algorithm you chose supports multiple input channels, you can specify those too. For example, when using the [XGBoost churn prediction notebook](#), you could add two channels: train and validation.

### Checkpoint Configuration

Checkpoints are periodically generated during training. You must choose an Amazon S3 location for the checkpoints to be saved. Checkpoints are used in metrics reporting, and are also used to resume managed spot training jobs. For more information, see [Use Checkpoints in Amazon SageMaker \(p. 1860\)](#).

### Output Data Configuration

You must define an Amazon S3 location for the artifacts of the training job to be stored. You have the option of adding encryption to the output using an Amazon Key Management Service (Amazon KMS) key.

### Configure Training Job Resources

Each training job definition for a tuning job must configure the resources to deploy, including instance types and counts, managed spot training, and stopping conditions.

#### Resource Configuration

Each training definition can have a different resource configuration. You choose the instance type and number of nodes.

#### Managed spot training

You can save computer costs for jobs if you have flexibility in start and end times by allowing SageMaker to use spare capacity to run jobs. For more information, see [Managed Spot Training in Amazon SageMaker \(p. 1859\)](#).

#### Stopping condition

The stopping condition specifies the maximum duration allowed per training job.

### Add or Clone a Training Job

Once you have created a training job definition for a tuning job, you are returned to the **Training Job Definition(s)** panel where you can create additional training job definitions to train additional algorithms. You can select the **Add training job definition** and work through the steps to define a training job again or choose **Clone** from the **Action** menu to replicate an existing training job definition and edit it for the new algorithm. The clone option can save time as it copies all of the job's settings, including the data channels, S3 storage locations. For more information on cloning, see [Manage Hyperparameter Tuning and Training Jobs \(p. 1754\)](#)

### Configure Tuning Job Resources

#### Resource Limits

You can specify the maximum number of concurrent training jobs that a hyperparameter tuning job can run concurrently (10 at most) and the maximum number of training jobs that the hyperparameter tuning job can run (500 at most). The number of parallel jobs should not exceed the number of nodes you have requested across all of your training definitions. The total number of jobs can't exceed the number of jobs that your definitions are expected to run.

### Review and Create HPO Tuning Job

Review the job settings, the training job definition(s), and resource limits. Then select **Create hyperparameter tuning job**.

## Manage Hyperparameter Tuning and Training Jobs

A tuning job can contain many training jobs and creating and managing these jobs and their definitions can become a complex and onerous task. SageMaker provides tools to help facilitate the management of these jobs. Tuning jobs you have run can be accessed from the Amazon SageMaker console at <https://console.amazonaws.cn/sagemaker/>. Select **Hyperparameter tuning job** from the **Training** menu to see the list. This page is also where you start the procedure to create a new tuning job by selecting **Create hyperparameter tuning job**.

To see the training jobs run as part of a tuning job, select one of the hyperparameter tuning jobs from the list. The tabs on the tuning job page allow you to inspect the training jobs, their definitions, the tags and configuration used for the tuning job, and the best training job found during tuning. You can select the best training job or any of the other training jobs that belong to the tuning job to see all of their settings. From here you can create a model that uses the hyperparameter values found by a training job by selecting **Create Model** or you can clone the training job by selecting **Clone**.

### Cloning

You can save time by cloning a training job that belongs to a hyperparameter tuning job. Cloning copies all of the job's settings, including data channels, S3 storage locations for output artifacts. You can do this for training jobs you have already run from the the tuning job page, as just described, or when you are creating additional training job definitions while creating a hyperparameter tuning job, as described in [Add or Clone a Training Job \(p. 1753\)](#) step of that procedure.

### Tagging

Automatic Model Tuning launches multiple training jobs within a single parent tuning job to discover the ideal weighting of model hyperparameters. Tags can be added to the parent tuning job as described in the [Define job settings \(p. 1750\)](#) section and these tags are then propagated to the individual training jobs underneath. Customers can use these tags for purposes such as cost allocation or access control. To add tags using the SageMaker SDK, use [AddTags](#) API. For more information about using tagging for Amazon resources, see [Tagging Amazon resources](#).

## Example: Hyperparameter Tuning Job

This example shows how to create a new notebook for configuring and launching a hyperparameter tuning job. The tuning job uses the [XGBoost Algorithm \(p. 1524\)](#) to train a model to predict whether a customer will enroll for a term deposit at a bank after being contacted by phone.

You use the low-level Amazon SDK for Python (Boto) to configure and launch the hyperparameter tuning job, and the Amazon Web Services Management Console to monitor the status of hyperparameter tuning jobs. You can also use the Amazon SageMaker high-level [Amazon SageMaker Python SDK](#) to configure, run, monitor, and analyze hyperparameter tuning jobs. For more information, see <https://github.com/aws/sagemaker-python-sdk>.

## Prerequisites

To run the code in this example, you need

- [An Amazon account and an administrator user \(p. 34\)](#)
- An Amazon S3 bucket for storing your training dataset and the model artifacts created during training
- [A running SageMaker notebook instance \(p. 53\)](#)

### Topics

- [Create a Notebook \(p. 1755\)](#)

- [Get the Amazon SageMaker Boto 3 Client \(p. 1755\)](#)
- [Get the SageMaker Execution Role \(p. 1756\)](#)
- [Specify a S3 Bucket to Upload Training Datasets and Store Output Data \(p. 1756\)](#)
- [Download, Prepare, and Upload Training Data \(p. 1756\)](#)
- [Configure and Launch a Hyperparameter Tuning Job \(p. 1757\)](#)
- [Monitor the Progress of a Hyperparameter Tuning Job \(p. 1761\)](#)
- [Clean up \(p. 1763\)](#)

## Create a Notebook

Create a Jupyter notebook that contains a pre-installed environment with the default Anaconda installation and Python3.

### To create a Jupyter notebook

1. Open the Amazon SageMaker console at <https://console.amazonaws.cn/sagemaker/>.
2. Open a running notebook instance, by choosing **Open** next to its name. The Jupyter notebook server page appears:

3. To create a notebook, choose **Files**, **New**, and **conda\_python3**..
4. Name the notebook.

## Next Step

[Get the Amazon SageMaker Boto 3 Client \(p. 1755\)](#)

## Get the Amazon SageMaker Boto 3 Client

Import Amazon SageMaker Python SDK, Amazon SDK for Python (Boto3), and other Python libraries. In a new Jupyter notebook, paste the following code to the first cell:

```
import sagemaker
import boto3

import numpy as np                               # For performing matrix operations and
numerical processing
import pandas as pd                             # For manipulating tabular data
from time import gmtime, strftime
import os

region = boto3.Session().region_name
smclient = boto3.Session().client('sagemaker')
```

The preceding code cell defines `region` and `smclient` objects that you will use to call the built-in XGBoost algorithm and set the SageMaker hyperparameter tuning job.

## Next Step

[Get the SageMaker Execution Role \(p. 1756\)](#)

## Get the SageMaker Execution Role

Get the execution role for the notebook instance. This is the IAM role that you created for your notebook instance. You pass the role to the tuning job.

```
from sagemaker import get_execution_role  
  
role = get_execution_role()  
print(role)
```

## Next Step

[Specify a S3 Bucket to Upload Training Datasets and Store Output Data \(p. 1756\)](#)

## Specify a S3 Bucket to Upload Training Datasets and Store Output Data

Set up a S3 bucket to upload training datasets and save training output data.

### To use a default S3 bucket

Use the following code to specify the default S3 bucket allocated for your SageMaker session. `prefix` is the path within the bucket where SageMaker stores the data for the current training job.

```
sess = sagemaker.Session()  
bucket = sess.default_bucket() # Set a default S3 bucket  
prefix = 'DEMO-automatic-model-tuning-xgboost-dm'
```

### (Optional) To use a specific S3 bucket

If you want to use a specific S3 bucket, use the following code and replace the strings to the exact name of the S3 bucket. The name of the bucket must contain `sagemaker`, and be globally unique. The bucket must be in the same Amazon Region as the notebook instance that you use for this example.

```
bucket = "sagemaker-your-preferred-s3-bucket"
```

### Note

The name of the bucket doesn't need to contain `sagemaker` if the IAM role that you use to run the hyperparameter tuning job has a policy that gives the `S3FullAccess` permission.

## Next Step

[Download, Prepare, and Upload Training Data \(p. 1756\)](#)

## Download, Prepare, and Upload Training Data

For this example, you use a training dataset of information about bank customers that includes the customer's job, marital status, and how they were contacted during the bank's direct marketing campaign. To use a dataset for a hyperparameter tuning job, you download it, transform the data, and then upload it to an Amazon S3 bucket.

For more information about the dataset and the data transformation that the example performs, see the `hpo_xgboost_direct_marketing_sagemaker_APIs` notebook in the **Hyperparameter Tuning** section of the **SageMaker Examples** tab in your notebook instance.

## Download and Explore the Training Dataset

To download and explore the dataset, run the following code in your notebook:

```
!wget -N https://archive.ics.uci.edu/ml/machine-learning-databases/00222/bank-additional.zip
!unzip -o bank-additional.zip
data = pd.read_csv('./bank-additional/bank-additional-full.csv', sep=';')
pd.set_option('display.max_columns', 500)      # Make sure we can see all of the columns
pd.set_option('display.max_rows', 5)            # Keep the output on one page
data
```

## Prepare and Upload Data

Before creating the hyperparameter tuning job, prepare the data and upload it to an S3 bucket where the hyperparameter tuning job can access it.

Run the following code in your notebook:

```
data['no_previous_contact'] = np.where(data['pdays'] == 999, 1, 0)
    # Indicator variable to capture when pdays takes a value of 999
data['not_working'] = np.where(np.in1d(data['job'], ['student', 'retired', 'unemployed']), 1, 0)
    # Indicator for individuals not actively employed
model_data = pd.get_dummies(data)
    # Convert categorical variables to sets of indicators
model_data = model_data.drop(['duration', 'emp.var.rate', 'cons.price.idx',
    'cons.conf.idx', 'euribor3m', 'nr.employed'], axis=1)

train_data, validation_data, test_data = np.split(model_data.sample(frac=1,
    random_state=1729), [int(0.7 * len(model_data)), int(0.9*len(model_data))])

pd.concat([train_data['y_yes'], train_data.drop(['y_no', 'y_yes'], axis=1)],
    axis=1).to_csv('train.csv', index=False, header=False)
pd.concat([validation_data['y_yes'], validation_data.drop(['y_no', 'y_yes'], axis=1)],
    axis=1).to_csv('validation.csv', index=False, header=False)
pd.concat([test_data['y_yes'], test_data.drop(['y_no', 'y_yes'], axis=1)],
    axis=1).to_csv('test.csv', index=False, header=False)

boto3.Session().resource('s3').Bucket(bucket).Object(os.path.join(prefix, 'train/train.csv')).upload_file('train.csv')
boto3.Session().resource('s3').Bucket(bucket).Object(os.path.join(prefix, 'validation/validation.csv')).upload_file('validation.csv')
```

## Next Step

[Configure and Launch a Hyperparameter Tuning Job \(p. 1757\)](#)

## Configure and Launch a Hyperparameter Tuning Job

To configure and launch a hyperparameter tuning job, complete the following steps.

### Topics

- [Specify the Hyperparameter Tuning Job Settings \(p. 1758\)](#)
- [Configure the Training Jobs \(p. 1759\)](#)

- [Name and Launch the Hyperparameter Tuning Job \(p. 1761\)](#)
- [Next Step \(p. 1761\)](#)

## Specify the Hyperparameter Tuning Job Settings

To specify settings for the hyperparameter tuning job, you define a JSON object. You pass the object as the value of the `HyperParameterTuningJobConfig` parameter to [CreateHyperParameterTuningJob](#) when you create the tuning job.

In this JSON object, you specify:

- The ranges of hyperparameters that you want to tune. For more information, see [Define Hyperparameter Ranges \(p. 1748\)](#)
- The limits of the resource that the hyperparameter tuning job can consume.
- The objective metric for the hyperparameter tuning job. An *objective metric* is the metric that the hyperparameter tuning job uses to evaluate the training job that it launches.

**Note**

To use your own algorithm for hyperparameter tuning, you need to define metrics for your algorithm. For information, see [Define Metrics \(p. 1747\)](#).

The hyperparameter tuning job defines ranges for the `eta`, `alpha`, `min_child_weight`, and `max_depth` hyperparameters of the [XGBoost Algorithm \(p. 1524\)](#) built-in algorithm. The objective metric for the hyperparameter tuning job maximizes the `validation:auc` metric that the algorithm sends to CloudWatch Logs.

```
tuning_job_config = {
    "ParameterRanges": {
        "CategoricalParameterRanges": [],
        "ContinuousParameterRanges": [
            {
                "MaxValue": "1",
                "MinValue": "0",
                "Name": "eta"
            },
            {
                "MaxValue": "2",
                "MinValue": "0",
                "Name": "alpha"
            },
            {
                "MaxValue": "10",
                "MinValue": "1",
                "Name": "min_child_weight"
            }
        ],
        "IntegerParameterRanges": [
            {
                "MaxValue": "10",
                "MinValue": "1",
                "Name": "max_depth"
            }
        ]
    },
    "ResourceLimits": {
        "MaxNumberOfTrainingJobs": 20,
        "MaxParallelTrainingJobs": 3
    },
    "Strategy": "Bayesian",
    "HyperParameterTuningJobObjective": {
```

```

        "MetricName": "validation:auc",
        "Type": "Maximize"
    }
}
```

## Configure the Training Jobs

To configure the training jobs that the tuning job launches, define a JSON object that you pass as the value of the `TrainingJobDefinition` parameter of the [CreateHyperParameterTuningJob](#) call.

In this JSON object, you specify:

- Optional—Metrics that the training jobs emit.

**Note**

Define metrics only when you use a custom training algorithm. Because this example uses a built-in algorithm, you don't specify metrics. For information about defining metrics, see [Define Metrics \(p. 1747\)](#).

- The container image that specifies the training algorithm.
- The input configuration for your training and test data.
- The storage location for the algorithm's output. Specify the S3 bucket where you want to store the output of the training jobs.
- The values of algorithm hyperparameters that are not tuned in the tuning job.
- The type of instance to use for the training jobs.
- The stopping condition for the training jobs. This is the maximum duration for each training job.

In this example, we set static values for the `eval_metric`, `num_round`, `objective`, `rate_drop`, and `tweedie_variance_power` parameters of the [XGBoost Algorithm \(p. 1524\)](#) built-in algorithm.

SageMaker Python SDK v1

```

from sagemaker.amazon.amazon_estimator import get_image_uri
training_image = get_image_uri(region, 'xgboost', repo_version='1.0-1')

s3_input_train = 's3://{}//{}//train'.format(bucket, prefix)
s3_input_validation = 's3://{}//{}//validation/'.format(bucket, prefix)

training_job_definition = {
    "AlgorithmSpecification": {
        "TrainingImage": training_image,
        "TrainingInputMode": "File"
    },
    "InputDataConfig": [
        {
            "ChannelName": "train",
            "CompressionType": "None",
            "ContentType": "csv",
            "DataSource": {

#### SageMaker Python SDK v2

```

training_image = sagemaker.image_uris.retrieve('xgboost', region, '1.0-1')

s3_input_train = 's3://{}{}/train'.format(bucket, prefix)
s3_input_validation = 's3://{}{}/validation/'.format(bucket, prefix)

training_job_definition = {
    "AlgorithmSpecification": {
        "TrainingImage": training_image,
        "TrainingInputMode": "File"
    },
    "InputDataConfig": [
        {
            "ChannelName": "train",
            "CompressionType": "None",
            "ContentType": "csv",
            "DataSource": {
                "S3DataSource": {
                    "S3DataDistributionType": "FullyReplicated",
                    "S3DataType": "S3Prefix",
                    "S3Uri": s3_input_train
                }
            }
        },
        {
            "ChannelName": "validation",
            "CompressionType": "None",
            "ContentType": "csv",
            "DataSource": {
                "S3DataSource": {
                    "S3DataDistributionType": "FullyReplicated",
                    "S3DataType": "S3Prefix",
                    "S3Uri": s3_input_validation
                }
            }
        }
    ]
}

```

```
        }
    ],
    "OutputDataConfig": {
        "S3OutputPath": "s3://{}{}/output".format(bucket,prefix)
    },
    "ResourceConfig": {
        "InstanceCount": 2,
        "InstanceType": "ml.c4.2xlarge",
        "VolumeSizeInGB": 10
    },
    "RoleArn": role,
    "StaticHyperParameters": {
        "eval_metric": "auc",
        "num_round": "100",
        "objective": "binary:logistic",
        "rate_drop": "0.3",
        "tweedie_variance_power": "1.4"
    },
    "StoppingCondition": {
        "MaxRuntimeInSeconds": 43200
    }
}
```

## Name and Launch the Hyperparameter Tuning Job

Now you can provide a name for the hyperparameter tuning job and then launch it by calling the [CreateHyperParameterTuningJob](#) API. Pass `tuning_job_config`, and `training_job_definition` that you created in previous steps as the values of the parameters.

```
tuning_job_name = "MyTuningJob"
smclient.create_hyper_parameter_tuning_job(HyperParameterTuningJobName = tuning_job_name,
                                            HyperParameterTuningJobConfig =
                                            tuning_job_config,
                                            TrainingJobDefinition = training_job_definition)
```

## Next Step

[Monitor the Progress of a Hyperparameter Tuning Job \(p. 1761\)](#)

## Monitor the Progress of a Hyperparameter Tuning Job

To monitor the progress of a hyperparameter tuning job and the training jobs that it launches, use the Amazon SageMaker console.

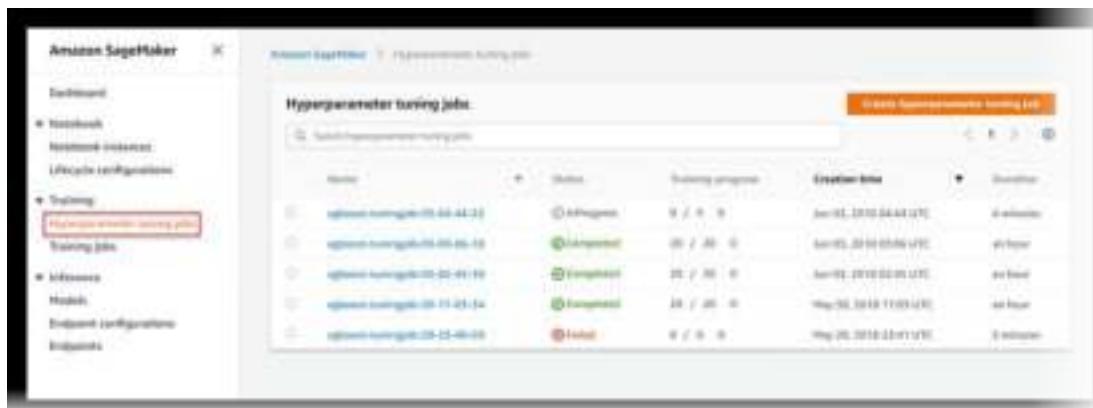

### Topics

- [View the Status of the Hyperparameter Tuning Job \(p. 1761\)](#)
- [View the Status of the Training Jobs \(p. 1762\)](#)
- [View the Best Training Job \(p. 1763\)](#)

## View the Status of the Hyperparameter Tuning Job

### To view the status of the hyperparameter tuning job

1. Open the Amazon SageMaker console at <https://console.amazonaws.cn/sagemaker/>.
2. Choose **Hyperparameter tuning jobs**.

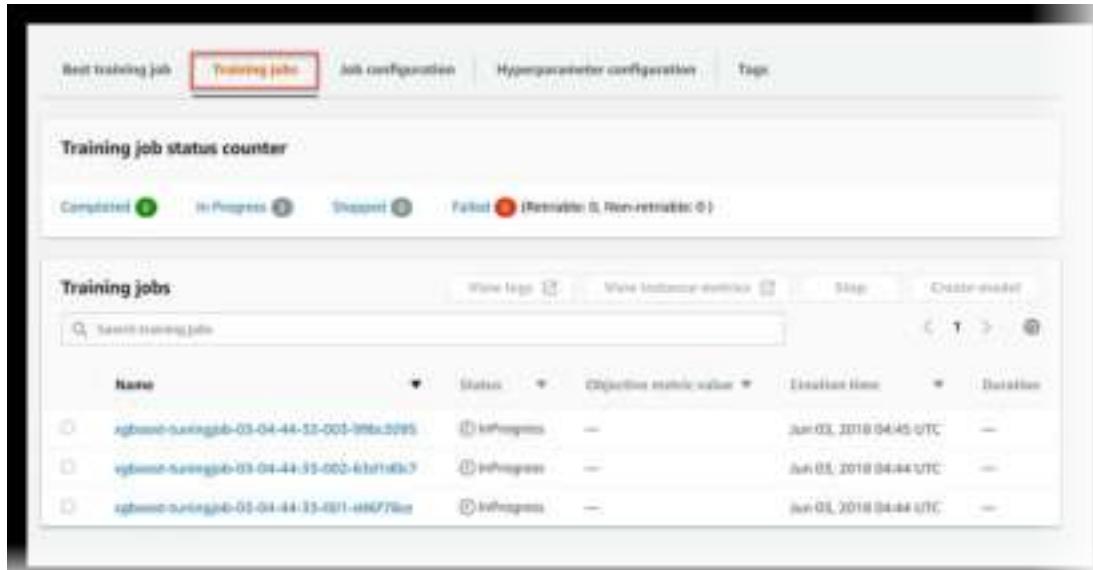

- In the list of hyperparameter tuning jobs, check the status of the hyperparameter tuning job you launched. A tuning job can be:
  - Completed**—The hyperparameter tuning job successfully completed.
  - InProgress**—The hyperparameter tuning job is in progress. One or more training jobs are still running.
  - Failed**—The hyperparameter tuning job failed.
  - Stopped**—The hyperparameter tuning job was manually stopped before it completed. All training jobs that the hyperparameter tuning job launched are stopped.
  - Stopping**—The hyperparameter tuning job is in the process of stopping.

## View the Status of the Training Jobs

### To view the status of the training jobs that the hyperparameter tuning job launched

- In the list of hyperparameter tuning jobs, choose the job that you launched.
- Choose **Training jobs**.

- View the status of each training job. To see more details about a job, choose it in the list of training jobs. To view a summary of the status of all of the training jobs that the hyperparameter tuning job launched, see **Training job status counter**.

A training job can be:

- **Completed**—The training job successfully completed.
- **InProgress**—The training job is in progress.
- **Stopped**—The training job was manually stopped before it completed.
- **Failed (Retryable)**—The training job failed, but can be retried. A failed training job can be retried only if it failed because an internal service error occurred.
- **Failed (Non-retryable)**—The training job failed and can't be retried. A failed training job can't be retried when a client error occurs.

## View the Best Training Job

A hyperparameter tuning job uses the objective metric that each training job returns to evaluate training jobs. While the hyperparameter tuning job is in progress, the best training job is the one that has returned the best objective metric so far. After the hyperparameter tuning job is complete, the best training job is the one that returned the best objective metric.

To view the best training job, choose **Best training job**.

The screenshot shows the 'Best training job' page in the Amazon SageMaker console. At the top, there are tabs: 'Best training job' (which is selected and highlighted in red), 'Training jobs', 'Job configuration', 'Hyperparameter configuration', and 'Tags'. Below the tabs, there's a section titled 'Best training job summary' with a 'Create model' button. It displays the following information:

Name	Status	Objective metric	Value
hyperparameter-tuning-job-12345-67890-1234567890	Completed	validation.auc	0.77256602048873

Below this is a section titled 'Best training job hyperparameters' with a search bar. It lists the following hyperparameters:

Name	Type	Value
_tuning_objective_metric	String	validation:auc
alpha	Continuous	1.9810243793579417
eta	Continuous	0.07404534782758304
eval_metric	String	auc

To deploy the best training job as a model that you can host at a SageMaker endpoint, choose **Create model**.

## Next Step

[Clean up \(p. 1763\)](#)

## Clean up

To avoid incurring unnecessary charges, when you are done with the example, use the Amazon Web Services Management Console to delete the resources that you created for it.

### Note

If you plan to explore other examples, you might want to keep some of these resources, such as your notebook instance, S3 bucket, and IAM role.

1. Open the SageMaker console at <https://console.amazonaws.cn/sagemaker/> and delete the notebook instance. Stop the instance before deleting it.
2. Open the Amazon S3 console at <https://console.amazonaws.cn/s3/> and delete the bucket that you created to store model artifacts and the training dataset.
3. Open the IAM console at <https://console.amazonaws.cn/iam/> and delete the IAM role. If you created permission policies, you can delete them, too.
4. Open the Amazon CloudWatch console at <https://console.amazonaws.cn/cloudwatch/> and delete all of the log groups that have names starting with /aws/sagemaker/.

## Stop Training Jobs Early

Stop the training jobs that a hyperparameter tuning job launches early when they are not improving significantly as measured by the objective metric. Stopping training jobs early can help reduce compute time and helps you avoid overfitting your model. To configure a hyperparameter tuning job to stop training jobs early, do one of the following:

- If you are using the Amazon SDK for Python (Boto 3), set the `TrainingJobEarlyStoppingType` field of the `HyperParameterTuningJobConfig` object that you use to configure the tuning job to `AUTO`.
- If you are using the [Amazon SageMaker Python SDK](#), set the `early_stopping_type` parameter of the `HyperParameterTuner` object to `Auto`.
- In the Amazon SageMaker console, in the **Create hyperparameter tuning job** workflow, under **Early stopping**, choose **Auto**.

For a sample notebook that demonstrates how to use early stopping, see [https://github.com/awslabs/amazon-sagemaker-examples/blob/master/hyperparameter\\_tuning/image\\_classification\\_early\\_stopping/hpo\\_image\\_classification\\_early\\_stopping.ipynb](https://github.com/awslabs/amazon-sagemaker-examples/blob/master/hyperparameter_tuning/image_classification_early_stopping/hpo_image_classification_early_stopping.ipynb) or open the `hpo_image_classification_early_stopping.ipynb` notebook in the **Hyperparameter Tuning** section of the **SageMaker Examples** in a notebook instance. For information about using sample notebooks in a notebook instance, see [Example Notebooks \(p. 131\)](#).

## How Early Stopping Works

When you enable early stopping for a hyperparameter tuning job, SageMaker evaluates each training job the hyperparameter tuning job launches as follows:

- After each epoch of training, get the value of the objective metric.
- Compute the running average of the objective metric for all previous training jobs up to the same epoch, and then compute the median of all of the running averages.
- If the value of the objective metric for the current training job is worse (higher when minimizing or lower when maximizing the objective metric) than the median value of running averages of the objective metric for previous training jobs up to the same epoch, SageMaker stops the current training job.

## Algorithms That Support Early Stopping

To support early stopping, an algorithm must emit objective metrics for each epoch. The following built-in SageMaker algorithms support early stopping:

- [Linear Learner Algorithm \(p. 1442\)](#)—Supported only if you use `objective_loss` as the objective metric.
- [XGBoost Algorithm \(p. 1524\)](#)

- [Image Classification Algorithm \(p. 1399\)](#)
- [Object Detection Algorithm \(p. 1479\)](#)
- [Sequence-to-Sequence Algorithm \(p. 1512\)](#)
- [IP Insights \(p. 1410\)](#)

**Note**

This list of built-in algorithms that support early stopping is current as of December 13, 2018. Other built-in algorithms might support early stopping in the future. If an algorithm emits a metric that can be used as an objective metric for a hyperparameter tuning job (preferably a validation metric), then it supports early stopping.

To use early stopping with your own algorithm, you must write your algorithms such that it emits the value of the objective metric after each epoch. The following list shows how you can do that in different frameworks:

TensorFlow

Use the `tf.keras.callbacks.ProgbarLogger` class. For information, see [https://www.tensorflow.org/api\\_docs/python/tf/keras/callbacks/ProgbarLogger](https://www.tensorflow.org/api_docs/python/tf/keras/callbacks/ProgbarLogger).

MXNet

Use the `mxnet.callback.LogValidationMetricsCallback`. For information, see <https://mxnet.apache.org/api/python/callback/callback.html>.

Chainer

Extend chainer by using the `extensions.Evaluator` class. For information, see <https://docs.chainer.org/en/v1.24.0/reference/extensions.html#evaluator>.

PyTorch and Spark

There is no high-level support. You must explicitly write your training code so that it computes objective metrics and writes them to logs after each epoch.

## Run a Warm Start Hyperparameter Tuning Job

Use warm start to start a hyperparameter tuning job using one or more previous tuning jobs as a starting point. The results of previous tuning jobs are used to inform which combinations of hyperparameters to search over in the new tuning job. Hyperparameter tuning uses either Bayesian or random search to choose combinations of hyperparameter values from ranges that you specify. For more information, see [How Hyperparameter Tuning Works \(p. 1745\)](#). Using information from previous hyperparameter tuning jobs can help increase the performance of the new hyperparameter tuning job by making the search for the best combination of hyperparameters more efficient.

**Note**

Warm start tuning jobs typically take longer to start than standard hyperparameter tuning jobs, because the results from the parent jobs have to be loaded before the job can start. The increased time depends on the total number of training jobs launched by the parent jobs.

Reasons you might want to consider warm start include:

- You want to gradually increase the number of training jobs over several tuning jobs based on the results you see after each iteration.
- You get new data, and want to tune a model using the new data.
- You want to change the ranges of hyperparameters that you used in a previous tuning job, change static hyperparameters to tunable, or change tunable hyperparameters to static values.
- You stopped a previous hyperparameter job early or it stopped unexpectedly.

### Topics

- [Types of Warm Start Tuning Jobs \(p. 1766\)](#)
- [Warm Start Tuning Restrictions \(p. 1766\)](#)
- [Warm Start Tuning Sample Notebook \(p. 1767\)](#)
- [Create a Warm Start Tuning Job \(p. 1767\)](#)

## Types of Warm Start Tuning Jobs

There are two different types of warm start tuning jobs:

### `IDENTICAL_DATA_AND_ALGORITHM`

The new hyperparameter tuning job uses the same input data and training image as the parent tuning jobs. You can change the hyperparameter ranges to search and the maximum number of training jobs that the hyperparameter tuning job launches. You can also change hyperparameters from tunable to static, and from static to tunable, but the total number of static plus tunable hyperparameters must remain the same as it is in all parent jobs. You cannot use a new version of the training algorithm, unless the changes in the new version do not affect the algorithm itself. For example, changes that improve logging or adding support for a different data format are allowed.

Use identical data and algorithm when you use the same training data as you used in a previous hyperparameter tuning job, but you want to increase the total number of training jobs or change ranges or values of hyperparameters.

When you run an warm start tuning job of type `IDENTICAL_DATA_AND_ALGORITHM`, there is an additional field in the response to [DescribeHyperParameterTuningJob](#) named `OverallBestTrainingJob`. The value of this field is the [TrainingJobSummary](#) for the training job with the best objective metric value of all training jobs launched by this tuning job and all parent jobs specified for the warm start tuning job.

### `TRANSFER_LEARNING`

The new hyperparameter tuning job can include input data, hyperparameter ranges, maximum number of concurrent training jobs, and maximum number of training jobs that are different than those of its parent hyperparameter tuning jobs. You can also change hyperparameters from tunable to static, and from static to tunable, but the total number of static plus tunable hyperparameters must remain the same as it is in all parent jobs. The training algorithm image can also be a different version from the version used in the parent hyperparameter tuning job. When you use transfer learning, changes in the dataset or the algorithm that significantly affect the value of the objective metric might reduce the usefulness of using warm start tuning.

## Warm Start Tuning Restrictions

The following restrictions apply to all warm start tuning jobs:

- A tuning job can have a maximum of 5 parent jobs, and all parent jobs must be in a terminal state (`Completed`, `Stopped`, or `Failed`) before you start the new tuning job.
- The objective metric used in the new tuning job must be the same as the objective metric used in the parent jobs.
- The total number of static plus tunable hyperparameters must remain the same between parent jobs and the new tuning job. Because of this, if you think you might want to use a hyperparameter as tunable in a future warm start tuning job, you should add it as a static hyperparameter when you create a tuning job.
- The type of each hyperparameter (continuous, integer, categorical) must not change between parent jobs and the new tuning job.

- The number of total changes from tunable hyperparameters in the parent jobs to static hyperparameters in the new tuning job, plus the number of changes in the values of static hyperparameters cannot be more than 10. Each value in a categorical hyperparameter counts against this limit. For example, if the parent job has a tunable categorical hyperparameter with the possible values `red` and `blue`, you change that hyperparameter to static in the new tuning job, that counts as 2 changes against the allowed total of 10. If the same hyperparameter had a static value of `red` in the parent job, and you change the static value to `blue` in the new tuning job, it also counts as 2 changes.
- Warm start tuning is not recursive. For example, if you create `MyTuningJob3` as a warm start tuning job with `MyTuningJob2` as a parent job, and `MyTuningJob2` is itself a warm start tuning job with a parent job `MyTuningJob1`, the information that was learned when running `MyTuningJob1` is not used for `MyTuningJob3`. If you want to use the information from `MyTuningJob1`, you must explicitly add it as a parent for `MyTuningJob3`.
- The training jobs launched by every parent job in a warm start tuning job count against the 500 maximum training jobs for a tuning job.
- Hyperparameter tuning jobs created before October 1, 2018 cannot be used as parent jobs for warm start tuning jobs.

## Warm Start Tuning Sample Notebook

For a sample notebook that shows how to use warm start tuning, see [https://github.com/awslabs/amazon-sagemaker-examples/blob/master/hyperparameter\\_tuning/image\\_classification\\_warmstart/hpo\\_image\\_classification\\_warmstart.ipynb](https://github.com/awslabs/amazon-sagemaker-examples/blob/master/hyperparameter_tuning/image_classification_warmstart/hpo_image_classification_warmstart.ipynb). For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see [Example Notebooks \(p. 131\)](#). Once you have created a notebook instance and opened it, select the **SageMaker Examples** tab to see a list of all the SageMaker samples. The warm start tuning example notebook is located in the **Hyperparameter tuning** section, and is named `hpo_image_classification_warmstart.ipynb`. To open a notebook, click on its **Use** tab and select **Create copy**.

## Create a Warm Start Tuning Job

You can use either the low-level Amazon SDK for Python (Boto 3) or the high-level SageMaker Python SDK to create a warm start tuning job.

### Topics

- [Create a Warm Start Tuning Job \( Low-level SageMaker API for Python \(Boto 3\)\) \(p. 1767\)](#)
- [Create a Warm Start Tuning Job \(SageMaker Python SDK\) \(p. 1768\)](#)

### Create a Warm Start Tuning Job ( Low-level SageMaker API for Python (Boto 3))

To use warm start tuning, you specify the values of a `HyperParameterTuningJobWarmStartConfig` object, and pass that as the `WarmStartConfig` field in a call to `CreateHyperParameterTuningJob`.

The following code shows how to create a `HyperParameterTuningJobWarmStartConfig` object and pass it to `CreateHyperParameterTuningJob` job by using the low-level SageMaker API for Python (Boto 3).

Create the `HyperParameterTuningJobWarmStartConfig` object:

```
warm_start_config = {
    "ParentHyperParameterTuningJobs" : [
        {"HyperParameterTuningJobName" : 'MyParentTuningJob'}
    ],
    "WarmStartType" : "IdenticalDataAndAlgorithm"
}
```

Create the warm start tuning job:

```
smclient = boto3.Session().client('sagemaker')
smclient.create_hyper_parameter_tuning_job(HyperParameterTuningJobName =
    'MyWarmStartTuningJob',
    HyperParameterTuningJobConfig = tuning_job_config, # See notebook for tuning
    configuration
    TrainingJobDefinition = training_job_definition, # See notebook for job definition
    WarmStartConfig = warm_start_config)
```

## Create a Warm Start Tuning Job (SageMaker Python SDK)

To use the [Amazon SageMaker Python SDK](#) to run a warm start tuning job, you:

- Specify the parent jobs and the warm start type by using a `WarmStartConfig` object.
- Pass the `WarmStartConfig` object as the value of the `warm_start_config` argument of a [HyperparameterTuner](#) object.
- Call the `fit` method of the [HyperparameterTuner](#) object.

For more information about using the [Amazon SageMaker Python SDK](#) for hyperparameter tuning, see <https://github.com/aws/sagemaker-python-sdk#sagemaker-automatic-model-tuning>.

This example uses an estimator that uses the [Image Classification Algorithm \(p. 1399\)](#) algorithm for training. The following code sets the hyperparameter ranges that the warm start tuning job searches within to find the best combination of values. For information about setting hyperparameter ranges, see [Define Hyperparameter Ranges \(p. 1748\)](#).

```
hyperparameter_ranges = {'learning_rate': ContinuousParameter(0.0, 0.1),
                         'momentum': ContinuousParameter(0.0, 0.99)}
```

The following code configures the warm start tuning job by creating a `WarmStartConfig` object.

```
from sagemaker.tuner import WarmStartConfig,
                           WarmStartTypes

parent_tuning_job_name = "MyParentTuningJob"
warm_start_config = WarmStartConfig(type=WarmStartTypes.IDENTICAL_DATA_AND_ALGORITHM,
                                     parents={parent_tuning_job_name})
```

Now set the values for static hyperparameters, which are hyperparameters that keep the same value for every training job that the warm start tuning job launches. In the following code, `imageclassification` is an estimator that was created previously.

```
imageclassification.set_hyperparameters(num_layers=18,
                                         image_shape='3,224,224',
                                         num_classes=257,
                                         num_training_samples=15420,
                                         mini_batch_size=128,
                                         epochs=30,
                                         optimizer='sgd',
                                         top_k='2',
                                         precision_dtype='float32',
                                         augmentation_type='crop')
```

Now create the `HyperparameterTuner` object and pass the `WarmStartConfig` object that you previously created as the `warm_start_config` argument.

```
tuner_warm_start = HyperparameterTuner(imageclassification,
```

```
'validation:accuracy',
hyperparameter_ranges,
objective_type='Maximize',
max_jobs=10,
max_parallel_jobs=2,
base_tuning_job_name='warmstart',
warm_start_config=warm_start_config)
```

Finally, call the `fit` method of the `HyperparameterTuner` object to launch the warm start tuning job.

```
tuner_warm_start.fit(
    {'train': s3_input_train, 'validation': s3_input_validation},
    include_cls_metadata=False)
```

## Resource Limits for Automatic Model Tuning

SageMaker sets the following default limits for resources used by automatic model tuning:

- Number of parallel (concurrent) hyperparameter tuning jobs: 100
- Number of hyperparameters that can be searched: 20

**Note**

Every possible value in a categorical hyperparameter counts against this limit.

- Number of metrics defined per hyperparameter tuning job: 20
- Number of parallel (concurrent) training jobs per hyperparameter tuning job: 10

**Note**

This can be increased to one hundred.

- [Bayesian search strategy] Number of training jobs per hyperparameter tuning job: 500
- [Random search strategy] Number of training jobs per hyperparameter tuning job: 500

**Note**

This can be increased up to ten thousand.

- Maximum run time for a hyperparameter tuning job: 30 days

When you plan hyperparameter tuning jobs, you also have to take into account the limits on training resources. For information about the default resource limits for SageMaker training jobs, see [SageMaker Limits](#). Every concurrent training instance on which all of your hyperparameter tuning jobs run counts against the total number of training instances allowed. For example, if you run 10 concurrent hyperparameter tuning jobs, each of those hyperparameter tuning jobs runs 100 total training jobs and 20 concurrent training jobs. Each of those training jobs runs on one **ml.m4.xlarge** instance. The following limits apply:

- Number of concurrent hyperparameter tuning jobs: You don't need to increase the limit, because 10 tuning jobs is below the limit of 100.
- Number of training jobs per hyperparameter tuning job: You don't need to increase the limit, because 100 training jobs is below the limit of 500.
- Number of concurrent training jobs per hyperparameter tuning job: You need to request a limit increase to 20, because the default limit is 10.
- SageMaker training **ml.m4.xlarge** instances: You need to request a limit increase to 200, because you have 10 hyperparameter tuning jobs, each of which is running 20 concurrent training jobs. The default limit is 20 instances.
- SageMaker training total instance count: You need to request a limit increase to 200, because you have 10 hyperparameter tuning jobs, each of which is running 20 concurrent training jobs. The default limit is 20 instances.

**To request a quota increase:**

1. Open the [Amazon Support Center](#) page, sign in if necessary, and then choose **Create case**.
2. On the **Create case** page, choose **Service limit increase**.
3. On the **Case details** panel, select **SageMaker Automatic Model Tuning [Hyperparameter Optimization]** for the **Limit type**.
4. On the **Requests** panel for **Request 1**, select the **Region**, the resource **Limit** to increase and the **New Limit value** you are requesting. Select **Add another request** if you have additional requests for quota increases.

The screenshot shows the 'Create case' interface. In the 'Service limit increase' section, there is a note: 'Request to increase the service limit of your resources'. Below this, under 'Case details', the 'Limit type' is set to 'SageMaker Automatic Model Tuning [Hyperparameter Optimization]'. In the 'Requests' section, there is a note: '(?) To request additional limit increases for the same limit type, choose Add another request. To request an increase for a different limit type, create a separate limit increase request.' A single request is listed: 'Request 1' with 'Region' set to 'US West (Oregon)', 'Resource Type' set to 'SageMaker Automatic Model Tuning [Hyperparameter Optimization]', and 'Limit' set to 'Max Parallel Training Jobs Per Tuning Job'. The 'New Limit value' field contains '100'. At the bottom of the Requests section is a button labeled 'Add Another Request'.

5. In the **Case description** panel, provide a description of your use case.
6. In the **Contact options** panel, select your preferred **Contact methods (Web, Chat or Phone)** and then choose **Submit**.

## Best Practices for Hyperparameter Tuning

Hyperparameter optimization is not a fully-automated process. To improve optimization, use the following guidelines when you create hyperparameters.

### Topics

- [Choosing the Number of Hyperparameters \(p. 1771\)](#)
- [Choosing Hyperparameter Ranges \(p. 1771\)](#)
- [Using Logarithmic Scales for Hyperparameters \(p. 1771\)](#)
- [Choosing the Best Number of Concurrent Training Jobs \(p. 1771\)](#)

- [Running Training Jobs on Multiple Instances \(p. 1771\)](#)

## Choosing the Number of Hyperparameters

The computational complexity of a hyperparameter tuning job depends primarily on the number of hyperparameters whose range of values Amazon SageMaker has to search through during optimization. Although you can simultaneously specify up to 20 hyperparameters to optimize for a tuning job, limiting your search to a much smaller number is likely to give you better results.

## Choosing Hyperparameter Ranges

The range of values for hyperparameters that you choose to search can significantly affect the success of hyperparameter optimization. Although you might want to specify a very large range that covers every possible value for a hyperparameter, you get better results by limiting your search to a small range of values. If you know that you get the best metric values within a subset of the possible range, consider limiting the range to that subset.

## Using Logarithmic Scales for Hyperparameters

During hyperparameter tuning, SageMaker attempts to figure out if your hyperparameters are log-scaled or linear-scaled. Initially, it assumes that hyperparameters are linear-scaled. If they are in fact log-scaled, it might take some time for SageMaker to discover that fact. If you know that a hyperparameter is log-scaled and can convert it yourself, doing so could improve hyperparameter optimization.

## Choosing the Best Number of Concurrent Training Jobs

When setting the resource limit `MaxParallelTrainingJobs` for the maximum number of concurrent training jobs that a hyperparameter tuning job can launch, consider the following tradeoff. Running more hyperparameter tuning jobs concurrently gets more work done quickly, but a tuning job improves only through successive rounds of experiments. Typically, running one training job at a time achieves the best results with the least amount of compute time.

## Running Training Jobs on Multiple Instances

When a training job runs on multiple instances, hyperparameter tuning uses the last-reported objective metric value from all instances of that training job as the value of the objective metric for that training job. Design distributed training jobs so that the objective metric reported is the one that you want.

# Distributed Training

## Get Started with Distributed Training

If you're familiar with distributed training, follow one of the links to your preferred strategy or framework to get started. Otherwise, continue on to the next section to learn some distributed training concepts.

### SageMaker distributed training libraries:

- [SageMaker's Distributed Data Parallel Library \(p. 1779\)](#)
- [SageMaker's Distributed Model Parallel \(p. 1795\)](#)

## Basic Distributed Training Concepts

SageMaker's distributed training libraries use the following distributed training terms and features.

### Datasets and Batches

- **Training Dataset:** All of the data you use to train the model.
- **Global batch size:** The number of records selected from the training dataset in each iteration to send to the GPUs in the cluster. This is the number of records over which the gradient is computed at each iteration. If data parallelism is used, it is equal to the total number of model replicas multiplied by the per-replica batch size: global batch size = # model replicas x per-replica batch size. A single batch of global batch size is often referred to as the *mini-batch* in machine learning literature.
- **Per-replica batch size:** When data parallelism is used, this is the number of records sent to each model replica. Each model replica performs a forward and backward pass with this batch to calculate weight updates. The resulting weight updates are synchronized (averaged) across all replicas before the next set of per-replica batches are processed.
- **Micro-batch:** A subset of the mini-batch or, if hybrid model and data parallelism is used , it is a subset of the per-replica sized batch . When you use SageMaker's distributed model parallelism library, each micro-batch is fed into the training pipeline one-by-one and follows an [execution schedule](#) defined by the library's runtime.

### Training

- **Epoch:** One training cycle through the entire dataset. It is common to have multiple iterations per an epoch. The number of epochs you use in training is unique on your model and use case.
- **Iteration:** A single forward and backward pass performed using a global batch sized batch (a mini-batch) of training data. The number of iterations performed during training is determined by the global batch size and the number of epochs used for training. For example, if a dataset includes 5,000 samples, and you use a global batch size of 500, it will take 10 iterations to complete a single epoch.
- **Learning rate:** A variable that influences the amount that weights are changed in response to the calculated error of the model. The learning rate plays an important role in the model's ability to converge as well as the speed and optimality of convergence.

### Instances and GPUs

- **Instances:** An Amazon [machine learning compute instance](#). These are also referred to as *nodes*.
- **Cluster size:** When using SageMaker's distributed training library, this is the number of instances multiplied by the number of GPUs in each instance. For example, if you use two ml.p3.8xlarge instances in a training job, which have 4 GPUs each, the cluster size is 8. While increasing cluster size can lead to faster training times, communication between instances must be optimized; Otherwise,

communication between the nodes can add overhead and lead to slower training times. The SageMaker distributed training library is designed to optimize communication between Amazon ML compute instances, leading to higher device utilization and faster training times.

### Distributed Training Solutions

- **Data parallelism:** A strategy in distributed training where a training dataset is split up across multiple processing nodes (such as Amazon ML Instances), and each processing node contains a *replica* of the model. Each node receives different batches of training data, performs a forward and backward pass, and shares weight updates with the other nodes for synchronization before moving on to the next batch and ultimately another epoch.
- **Model parallelism:** A strategy in distributed training where the model partitioned across multiple processing nodes (such as Amazon ML Instances). The model might be complex and have a large number of hidden layers and weights, making it unable to fit in the memory of a single node. Each node carries a subset of the model, through which the data flows and the transformations are shared and compiled. The efficiency of model parallelism, in terms of GPU utilization and training time, is heavily dependent on how the model is partitioned and the execution schedule used to perform forward and backward passes.
- **Pipeline Execution Schedule (Pipelining):** The pipeline execution schedule determines the order in which computations (micro-batches) are made and data is processed across devices during model training. Pipelining is a technique to achieve true parallelization in model parallelism and overcome the performance loss due to sequential computation by having the GPUs compute simultaneously on different data samples. To learn more, see [Pipeline Execution Schedule](#).

### Example

The following example demonstrates how these terms might be used to describe a training job that uses hybrid model and data parallelism:

A 2-way data parallelism and 4-way model parallelism training job is launched with a global batch size of 64 images. This training job requires a total of 8 GPUs. Each of the two model replicas processes a per-replica batch of size 32. During the forward and backward pass, a per-replica batch is further divided up into micro-batches. These micro-batches are processed in an interleaved fashion using a pipelined execution schedule.

The training dataset includes 640 images, and so a single epoch takes 10 iterations.

## Advanced Concepts

Machine Learning (ML) practitioners commonly face two scaling challenges when training models: *scaling model size* and *scaling training data*. While model size and complexity can result in better accuracy, there is a limit to the model size you can fit into a single CPU or GPU. Furthermore, scaling model size may result in more computations and longer training times.

Not all models handle training data scaling equally well. Some algorithms need to ingest all the training data *in memory* for training. They only scale vertically, and to bigger and bigger instance types. Some algorithms have the disadvantage of scaling super-linearly with dataset size. For example, the computational load of a nearest-neighbor search for all records of an N-rows dataset scales in N squared. In most cases, scaling training data results in longer training times.

Deep Learning (DL) is a specific family of ML algorithms consisting of several layers of artificial neural networks. The most common training method is with mini-batch Stochastic Gradient Descent (SGD). In mini-batch SGD, the model is trained by conducting small iterative changes of its coefficients in the direction that reduces its error. Those iterations are conducted on equally sized subsamples of the training dataset called *mini-batches*. For each mini-batch, the model is run in each record of the mini-batch, its error measured and the gradient of the error estimated. Then the average gradient is measured

across all the records of the mini-batch and provides an update direction for each model coefficient. One full pass over the training dataset is called an *epoch*. Model trainings commonly consist of dozens to hundreds of epochs. Mini-batch SGD has several benefits: First, its iterative design makes training time theoretically linear of dataset size. Second, in a given mini-batch each record is processed individually by the model without need for inter-record communication other than the final gradient average. The processing of a mini-batch is consequently particularly suitable for parallelization and distribution.

Parallelizing SGD training by distributing the records of a mini-batch over different computing devices is called *data parallel distributed training*, and is the most commonly used DL distribution paradigm. Data parallel training is a relevant distribution strategy to scale the mini-batch size and process each mini-batch faster. However, data parallel training comes with the extra complexity of having to compute the mini-batch gradient average with gradients coming from all the workers and communicating it to all the workers, a step called *allreduce* that can represent a growing overhead, as the training cluster is scaled, and that can also drastically penalize training time if improperly implemented or implemented over improper hardware substracts.

Data parallel SGD still requires developers to be able to fit at least the model and a single record in a computing devices, like a single CPU or GPU. When training very large models such as large transformers in Natural Language Processing (NLP), or segmentation models over high-resolution images, there may be situations in which this is not feasible. An alternative way to break up the workload is to partition the model over multiple computing devices, an approach called *model-parallel distributed training*.

## Strategies

Distributed training is usually split by two approaches: data parallel and model parallel. *Data parallel* is the most common approach to distributed training: You have a lot of data, batch it up, and send blocks of data to multiple CPUs or GPUs (nodes) to be processed by the neural network or ML algorithm, then combine the results. The neural network is the same on each node. A *model parallel* approach is used with large models that won't fit in a node's memory in one piece; it breaks up the model and places different parts on different nodes. In this situation, you need to send your batches of data out to each node so that the data is processed on all parts of the model.

The terms *network* and *model* are often used interchangeably: A large model is really a large network with many layers and parameters. Training with a large network produces a large model, and loading the model back onto the network with all your pre-trained parameters and their weights loads a large model into memory. When you break apart a model to split it across nodes, you're also breaking apart the underlying network. A network consists of layers, and to split up the network, you put layers on different compute devices.

A common pitfall of naively splitting layers across devices is severe GPU under-utilization. Training is inherently sequential in both forward and backward passes, and at a given time, only one GPU can actively compute, while the others wait on the activations to be sent. Modern model parallel libraries solve this problem by using pipeline execution schedules to improve device utilization. However, only the Amazon SageMaker's distributed model parallel library includes automatic model splitting. The two core features of the library, automatic model splitting and pipeline execution scheduling, simplifies the process of implementing model parallelism by making automated decisions that lead to efficient device utilization.

## Train with Data Parallel and Model Parallel

If you are training with a large dataset, start with a data parallel approach. If you run out of memory during training, you may want to switch to a model parallel approach, or try hybrid model and data parallelism. You can also try the following to improve performance with data parallel:

- Change your model's hyperparameters.
- Reduce the batch size.
- Keep reducing the batch size until it fits. If you reduce batch size to 1, and still run out of memory, then you should try model-parallel training.

Try gradient compression (fp16, fp8):

- On NVIDIA TensorCore-equipped hardware, using [mixed-precision training](#) creates both speed-up and memory consumption reduction.

Try reducing the input size:

- Reduce the NLP sequence length if you increase the sequence link, need to adjust the batch size down, or adjust the GPUs up to spread the batch.
- Reduce image resolution.

Check if you use batch normalization, since this can impact convergence. When you use distributed training, your batch is split across GPUs and the effect of a much lower batch size can be a higher error rate thereby disrupting the model from converging. For example, if you prototyped your network on a single GPU with a batch size of 64, then scaled up to using four p3dn.24xlarge, you now have 32 GPUs and your per-GPU batch size drops from 64 to 2. This will likely break the convergence you saw with a single node.

Start with model-parallel training when:

- Your model does not fit on a single device.
- Due to your model size, you're facing limitations in choosing larger batch sizes, such as if your model weights take up most of your GPU memory and you are forced to choose a smaller, suboptimal batch size.

To learn more about the SageMaker distributed libraries, see the following:

- [SageMaker's Distributed Data Parallel Library \(p. 1779\)](#)
- [SageMaker's Distributed Model Parallel \(p. 1795\)](#)

## Optimize Distributed Training

Customize hyperparameters for your use case and your data to get the best scaling efficiency. In the following discussion, we highlight some of the most impactful training variables and provide references to state-of-the-art implementations so you can learn more about your options. Also, we recommend that you refer to your preferred framework's distributed training documentation.

- [Apache MXNet distributed training](#)
- [PyTorch distributed training](#)
- [TensorFlow distributed training](#)

## Batch Size

SageMaker distributed toolkits generally allow you to train on bigger batches. For example, if a model fits within a single device but can only be trained with a small batch size, using either model-parallel training or data parallel training enables you to experiment with larger batch sizes.

Be aware that batch size directly influences model accuracy by controlling the amount of noise in the model update at each iteration. Increasing batch size reduces the amount of noise in the gradient estimation, which can be beneficial when increasing from very small batches sizes, but can result in degraded model accuracy as the batch size increases to large values.

### Tip

Adjust your hyperparameters to ensure that your model trains to a satisfying convergence as you increase its batch size.

A number of techniques have been developed to maintain good model convergence when batch is increased.

## Mini-Batch Size

In SGD, the mini-batch size quantifies the amount of noise present in the gradient estimation. A small mini-batch results in a very noisy mini-batch gradient, which is not representative of the true gradient over the dataset. A large mini-batch results in a mini-batch gradient close to the true gradient over the dataset and potentially not noisy enough—likely to stay locked in irrelevant minima.

To learn more about these techniques, see the following papers:

- [Accurate, Large Minibatch SGD:Training ImageNet in 1 Hour](#), Goya et al.
- [PowerAI DDL](#), Cho et al.
- [Scale Out for Large Minibatch SGD: Residual Network Training on ImageNet-1K with Improved Accuracy and Reduced Time to Train](#), Codreanu et al.
- [ImageNet Training in Minutes](#), You et al.
- [Large Batch Training of Convolutional Networks](#), You et al.
- [Large Batch Optimization for Deep Learning: Training BERT in 76 Minutes](#), You et al.
- [Accelerated Large Batch Optimization of BERT Pretraining in 54 minutes](#), Zheng et al.
- [Deep Gradient Compression](#), Lin et al.

## Scenarios

The following sections cover scenarios in which you may want to scale up training, and how you can do so using Amazon resources.

### Scaling from a Single GPU to Many GPUs

The amount of data or the size of the model used in machine learning can create situations in which the time to train a model is longer than you are willing to wait. Sometimes, the training doesn't work at all because the model or the training data is too large. One solution is to increase the number of GPUs you use for training. On an instance with multiple GPUs, like a p3.16xlarge that has eight GPUs, the data and processing is split across the eight GPUs. When you use distributed training libraries, this can result in a near-linear speedup in the time it takes to train your model. It takes slightly over 1/8 the time it would have taken on p3.2xlarge with one GPU.

Instance type	GPUs
p3.2xlarge	1
p3.8xlarge	4
p3.16xlarge	8
p3dn.24xlarge	8

#### Note

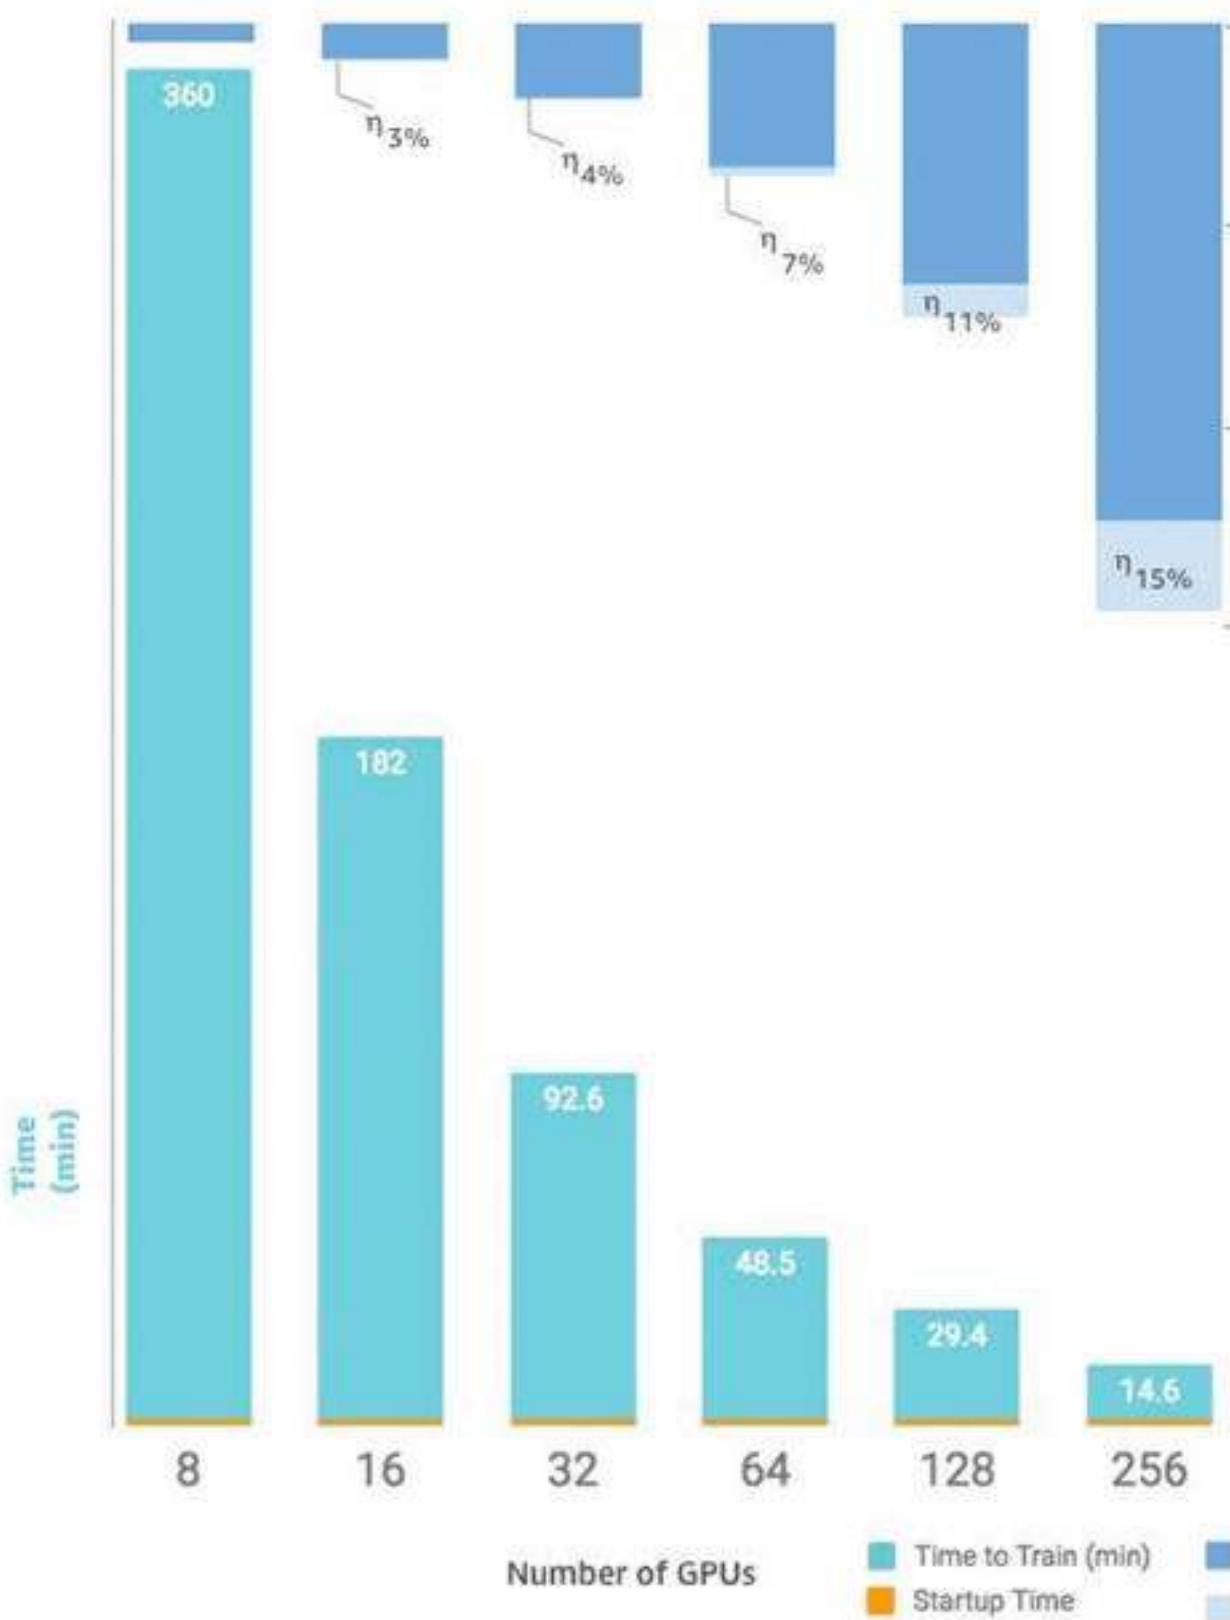

The ml instance types used by SageMaker training have the same number of GPUs as the corresponding p3 instance types. For example, ml.p3.8xlarge has the same number of GPUs as p3.8xlarge - 4.

## Scaling from a Single Instance to Multiple Instances

If you want to scale your training even further, you can use more instances. However, you should choose a larger instance type before you add more instances. Review the previous table to see how many GPUs are in each p3 instance type.

If you have made the jump from a single GPU on a p3.2xlarge to four GPUs on a p3.8xlarge, but decide that you require more processing power, you may see better performance and incur lower costs if you choose a p3.16xlarge before trying to increase instance count. Depending on the libraries you use, when you keep your training on a single instance, performance is better and costs are lower than a scenario where you use multiple instances.

When you are ready to scale the number of instances, you can do this with SageMaker Python SDK's `estimator` function by setting your `instance_count`. For example, you can set `instance_type = p3.16xlarge` and `instance_count = 2`. Instead of the eight GPUs on a single p3.16xlarge, you have 16 GPUs across two identical instances. The following chart shows [scaling and throughput starting with eight GPUs](#) on a single instance and increasing to 64 instances for a total of 256 GPUs.

## Availability Zones and Network Backplane

With multiple instances, it's important to understand the network that connects the instances, how they read the training data, and how they share information between themselves (for example, communication between the nodes in the cluster when doing an AllReduce operation).

First, your instances need to be in the same Region and same Availability Zone. For example, instances in us-west-2 must all be in us-west-2a. When you use the SageMaker Python SDK, this is handled for you. If you use Amazon EC2 and orchestrate your own training clusters, you need to be aware of this, or your training speeds suffer.

Your training data should also be in the same Availability Zone. When you use a SageMaker estimator, you pass in the Region and the S3 bucket, and if the data is not in the Region you set, you get an error.

## Optimized GPU, Network, and Storage

The p3dn.24xlarge instance type was designed for fast local storage and a fast network backplane with up to 100 gigabits, and we highly recommend it as the most performant option for distributed training. SageMaker supports streaming data modes from S3, referred to as pipe mode. For HPC loads like distributed training, we recommend [Amazon Fsx](#) for your file storage.

## Custom Training Scripts

While SageMaker makes it simple to deploy and scale the number of instances and GPUs, depending on your framework of choice, managing the data and results can be very challenging, which is why external supporting libraries are often used. This most basic form of distributed training requires modification of your training script to manage the data distribution.

SageMaker also supports Horovod and implementations of distributed training native to each major deep learning framework. If you choose to use examples from these frameworks, you can follow SageMaker's [container guide](#) for Deep Learning Containers, and various [example notebooks](#) that demonstrate implementations.

## SageMaker Built-In Distributed Training Features

The [SageMaker built-in libraries of algorithms](#) consists of 18 popular machine learning algorithms. Many of them were rewritten from scratch to be scalable and distributed out of the box. If you want to use distributed **deep learning** training code, we recommend Amazon SageMaker's distributed training libraries. SageMaker's distributed training libraries make it easier for you to write highly scalable and cost-effective custom data parallel and model parallel deep learning training jobs.

SageMaker distributed training libraries offer both data parallel and model parallel training strategies. It combines software and hardware technologies to improve inter-GPU and inter-node communications. It extends SageMaker's training capabilities with built-in options that require only small code changes to your training scripts.

- [SageMaker's Distributed Data Parallel Library \(p. 1779\)](#)
- [SageMaker's Distributed Model Parallel \(p. 1795\)](#)

## SageMaker's Distributed Data Parallel Library

### Important

To use new features with an existing notebook instance or Studio application, restart the notebook instance or Studio application to get the latest updates.

SageMaker's distributed data parallel library extends SageMaker's training capabilities on deep learning models with near-linear scaling efficiency, achieving fast time-to-train with minimal code changes.

- The library optimizes your training job for Amazon network infrastructure and Amazon EC2 instance topology.
- The library takes advantage of gradient updates to communicate between nodes with a custom AllReduce algorithm.

When training a model on a large amount of data, machine learning practitioners often turn to distributed training to reduce the time to train. In some cases, where time is of the essence, the business requirement is to finish training as quickly as possible or at least within a constrained time period. Then, distributed training is scaled to use a cluster of multiple nodes—not just multiple GPUs in a computing instance, but multiple instances with multiple GPUs. As the cluster size increases, so does the significant drop in performance. This drop in performance is primarily caused by the communications overhead between nodes in a cluster.

SageMaker's distributed library offers two options for distributed training: model parallel and data parallel. This guide focuses on how to train models using a data parallel strategy. For more information on training with a model-parallel strategy, refer to [SageMaker's Distributed Model Parallel \(p. 1795\)](#).

### Topics

## Introduction to SageMaker's Distributed Data Parallel Library

### Why Use SageMaker Distributed Data Parallel Library?

SageMaker's distributed data parallel library addresses communications overhead in two ways:

1. The library performs AllReduce, a key operation during distributed training that is responsible for a large portion of communication overhead.
2. The library performs optimized node-to-node communication by fully utilizing Amazon's network infrastructure and Amazon EC2 instance topology.

Use this data parallel library to increase speed by up to 25% in training models such as BERT. While implementations like Horovod offer sub-linear performance at scale, this library offers near-linear performance at scale. This means that you get a faster training time and a lower cost to train a model.

### Training Benchmarks

#### PyTorch with SageMaker's data parallel library

Model	Setup	Throughput			Scaling Efficiency		
		PT-DDP	SageMaker	Speed up	PT-DDP	SageMaker	Improvement
BERT Large (finetuned)	2 node p3dn.24xlarge	1752	2479	41%	66%	90%	20%
	4 node p3dn.24xlarge	3017	4903	52%	55%	84%	38%
	8 node p3dn.24xlarge	7429	8581	13%	67%	78%	11%
MaskRCNN (finetuned)	2 node p3dn.24xlarge	152	158	4%	10%	85%	3%
	4 node p3dn.24xlarge	258	307	19%	10%	83%	15%
	8 node p3dn.24xlarge	545	617	13%	74%	84%	9%

Using instance type p3dn.24xlarge and on 2, 4, and 8 node clusters:

- *BERT*: When used with PyTorch, the SageMaker library is 41%, 52%, and 13% faster than PyTorch-DDP.
- *MaskRCNN*: When used with PyTorch, the SageMaker library is 4%, 19%, and 15% faster than PyTorch-DDP.

These benchmarks were run on PyTorch v1.6 using m1.p3dn.24xlarge instances. You can find the training code on the [SageMaker examples website](#). The examples website also has benchmark training code for these models [using TensorFlow 2.3](#).

## Optimal Bandwidth Use with Balanced Fusion Buffer

SageMaker's distributed data parallel library uses a communication pattern similar to parameter servers to reduce the amount of data transferred and the number of steps involved in averaging gradients from multiple GPUs. It also uses a new technique called balanced fusion buffers to make optimal use of the bandwidth available across all nodes in the cluster.

One key disadvantage of traditional parameter servers is their suboptimal use of available network bandwidth. Parameter servers treat variables as atomic units and place each variable on one server. Since gradients become available sequentially during the backward pass, at any given instant, there is imbalance in the volume of data being sent and received from different servers. Some servers are receiving and sending more data, some less, and some none. This problem becomes worse as the number of parameter servers increases.

The library addresses these problems by introducing *balanced fusion buffers*. A balanced fusion buffer is a buffer in the GPU that holds the gradients until the size of the buffer exceeds a threshold. In a setup with N parameter servers, when the buffer exceeds the threshold, the balanced fusion buffer is copied to CPU memory, sharded into N parts, and the ith part is sent to the ith parameter server. Each server receives exactly the same number of bytes from a balanced fusion buffer. The ith server receives the ith partition of the balanced fusion buffer from all workers, sums them up, and sends the results back to all workers. Since all the servers participate equally in averaging each balanced fusion buffer, server bandwidth is efficiently utilized.

## Optimal GPU Usage with Efficient AllReduce Overlapping with a Backward Pass

SageMaker's distributed data parallel library achieves optimal overlapping of the AllReduce operation with the backward pass, significantly improving the GPU utilization, and achieves near-linear scaling efficiency and faster time to train by optimizing tasks between CPUs and GPUs. The library performs AllReduce in parallel while GPU is computing gradients without taking away additional GPU cycles, which makes the library faster.

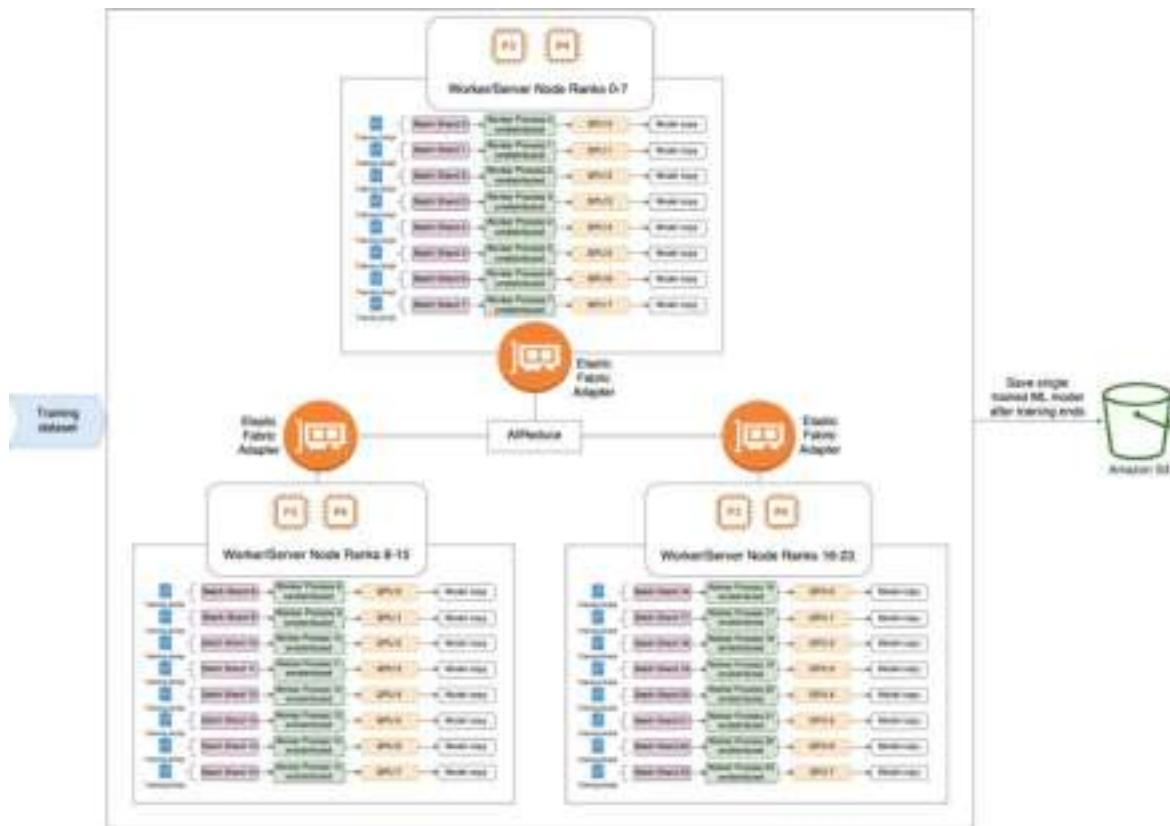

- *Leverages CPUs:* The library uses CPUs to AllReduce gradients, offloading this task from the GPUs.
- *Improved GPU usage:* The cluster's GPUs focus on computing gradients, improving their utilization throughout training.

## SageMaker Distributed Data Parallel Architecture

The library supports larger compute instances that have 8 GPUs per node: `m1.p3.16xlarge`, `m1.p3dn.24xlarge`, and `m1.p4d.24xlarge`. The high-level workflow of the SageMaker distributed data parallel library is as following:

1. The library assigns ranks to GPUs (workers).
2. At each iteration, the library divides each global batch by the total number of workers (world size) and assigns small batches (batch shards) to the workers.
  - The size of the global batch is `(number of nodes in a cluster) * (number of GPUs per node) * (per batch shard)`.
  - A batch shard (small batch) is a subset of dataset assigned to each GPU (worker) per iteration.
3. The library launches a training script on each worker.
4. The library manages copies of model weights and gradients from the workers at the end of every iteration.
5. The library synchronizes model weights and gradients across the workers to aggregate a single trained model.

The following architecture diagram shows an example of how the library sets up data parallelism for a cluster of 3 nodes.

To start using the SageMaker distributed data parallel library, see [Use the SageMaker Distributed Data Parallel API \(p. 1783\)](#) to set up a SageMaker estimator through [Amazon SageMaker Python SDK](#), and [Modify Your Training Script using the SageMaker Data Parallel Library \(p. 1787\)](#) to adapt your training script using the SageMaker distributed data parallel library.

## Use the SageMaker Distributed Data Parallel API

Use this page to learn how you can import and use SageMaker's distributed data parallel library. For API specifications, refer to [distributed data parallel](#) in the SageMaker Python SDK documentation.

### Use SageMaker's Distributed Data Parallel Library

To use SageMaker's distributed data parallel library, you start with a training script. Just as with any training job on SageMaker, you use your training script to launch a SageMaker training job. To get started, we recommend that you use the SageMaker data parallel library in the following ways:

- Using a [SageMaker notebook instance](#)
- Using [SageMaker Studio](#)

With either option, you can then use the [Distributed Training Jupyter Notebook Examples \(p. 1819\)](#) provided with this documentation to get started.

### Use the Data Parallel Library with SageMaker's Python SDK

To use SageMaker's distributed data parallel library, you must create a training script for one of the supported frameworks and launch the training job using the SageMaker Python SDK. To learn how you can incorporate the library into a training script, see [Modify Your Training Script Using SageMaker's Distributed Model Parallel Library \(p. 1804\)](#). The library API documentation is located in the SageMaker Python SDK. See SageMaker's [data parallel API documentation](#).

SageMaker supports the following training environment configurations:

- You can use a prebuilt TensorFlow or PyTorch container.
- You can customize SageMaker prebuilt containers or extend them to handle any additional functional requirements for your algorithm or model that the prebuilt SageMaker Docker image doesn't support. For an example of how you can extend a pre-built container, see [Extend a Prebuilt Container](#).

To extend a pre-built container, or adapt your own container to use the library, you must use one of the PyTorch or TensorFlow GPU general framework base-images. The distributed data parallel library is included in all CUDA 11 (cu11x) TensorFlow 2.3.x and PyTorch 1.6.x versioned images and later. See [Available Deep Learning Containers Images](#) for a list of available images.

#### Important

It is recommended that you use the image that contains the latest version of TensorFlow or PyTorch to access the most up to date version of the SageMaker distributed data parallel library. All images that include TensorFlow 2.4.1 and PyTorch 1.8.1 versions and later support EFA instance types (`ml.p3dn.24xlarge`, `ml.p4d.24xlarge`).

For example, if you are using PyTorch 1.8.1, your Dockerfile should contain a `FROM` statement similar to the following:

```
# SageMaker PyTorch image
FROM 763104351884.dkr.ecr.us-east-1.amazonaws.com/pytorch-training:1.8.1-gpu-py36-cu111-
ubuntu18.04

ENV PATH="/opt/ml/code:${PATH}"
```

```
# this environment variable is used by the SageMaker PyTorch container to determine our
# user code directory.
ENV SAGEMAKER_SUBMIT_DIRECTORY /opt/ml/code

# /opt/ml and all subdirectories are utilized by SageMaker, use the /code subdirectory to
# store your user code.
COPY cifar10.py /opt/ml/code/cifar10.py

# Defines cifar10.py as script entrypoint
ENV SAGEMAKER_PROGRAM cifar10.py
```

- You can adapt your own Docker container to work with SageMaker using the [SageMaker Training toolkit](#). For an example, see [Adapting Your Own Training Container](#).

In all cases, you launch your job using a SageMaker Python SDK Estimator.

If you are using the SageMaker pre-built PyTorch or TensorFlow containers, see the following section to learn how configure an Estimator to use the library.

If you bring your own container or extend a pre-built container, you can create an instance of the Estimator class with the desired Docker image.

## TensorFlow Estimator

You can use SageMaker's [distributed data parallel library API](#) by specifying `smdistributed.dataparallel` as the distribution strategy in the SageMaker TensorFlow Estimator API. Refer to [SageMaker TensorFlow Estimator API documentation](#) for full details about the API.

```
class sagemaker.tensorflow.estimator.TensorFlow(py_version=None, framework_version=None, model_dir=None)
```

The following two parameters of the SageMaker Python SDK TensorFlow estimator are required to use `smdistributed.dataparallel` with TensorFlow.

**distribution(dict)(optional)**: A dictionary with information on how to run distributed training (default: None).

- To use `smdistributed.dataparallel` as a distribution strategy, use the following option:

```
distribution = { "smdistributed": { "dataparallel": { "enabled": True } } }
```

- **custom\_mpi\_options (str)(optional)**: Custom MPI options. The following is an example of how you can use this parameter when defining distribution. To learn more, see [Custom MPI Options \(p. 1793\)](#).

```
distribution = {
    "smdistributed": {
        "dataparallel": {
            "enabled": True,
            "custom_mpi_options": "-verbose -x NCCL_DEBUG=VERSION"
        }
    }
}
```

**train\_instance\_type (str)(required)**: A type of Amazon EC2 instance to use.

- If the `smdistributed.dataparallel` distribution strategy is used, the allowed instance types are: `ml.p4d.24xlarge`, `ml.p3dn.24xlarge`, and `ml.p3.16xlarge`. For best performance, it is

recommended that you use an EFA supported instance, `ml.p3dn.24xlarge` or `ml.p4d.24xlarge`, with the latest supported version of TensorFlow.

### Example

```
from sagemaker.tensorflow import TensorFlow

tf_estimator = TensorFlow(
    base_job_name = "training_job_name_prefix",
    entry_point="tf-train.py",
    role="SageMakerRole",
    framework_version="2.4.1",
    # You must set py_version to py36
    py_version="py37",
    # For training with multi node distributed training, set this count.
    # Example: 2,3,4,..8
    instance_count=2,
    # For training with p3dn instance use - ml.p3dn.24xlarge
    instance_type="ml.p3.16xlarge",
    # Training using smdistributed.dataparallel Distributed Training Framework
    distribution={"smdistributed": {"dataparallel": {"enabled": True}}}
)

tf_estimator.fit("s3://bucket/path/to/training/data")
```

### Note

If you are using the SageMaker Python SDK 1.x, you need to use hyperparameters to specify to use `smdistributed.dataparallel` as the distributed training strategy.

```
from sagemaker.tensorflow import TensorFlow
tf_estimator = TensorFlow(
    ...
    # Training using smdistributed.dataparallel Distributed
    Training Framework

    hyperparameters={"sagemaker_distributed_dataparallel_enabled": True},
    ...
)
tf_estimator.fit("s3://bucket/path/to/training/data")
```

## PyTorch Estimator

You can use SageMaker's [distributed data parallel library API](#) by specifying `smdistributed.dataparallel` as the distribution strategy in SageMaker PyTorch Estimator API. Refer to the [SageMaker PyTorch Estimator API specification](#) for full details of the API.

```
class sagemaker.pytorch.estimator.PyTorch(py_version=None, framework_version=None, model_dir=None, image_name=None, hyperparameters=None, distribution=None, kwargs)
```

The following two parameters of the SageMaker PyTorch Estimator are necessary for using `smdistributed.dataparallel` on SageMaker with PyTorch.

**distribution (dict)(optional):** A dictionary with information on how to run distributed training (default: None).

- To uses `smdistributed.dataparallel` as a distribution strategy, use the following option:

```
distribution={ "smdistributed": { "dataparallel": { "enabled": True } } }
```

- **`custom_mpi_options (str)(optional)`**: Custom MPI options. The following is an example of how you can use this parameter when defining distribution. To learn more, see [Custom MPI Options \(p. 1793\)](#).

```

distribution = {
    "smdistributed": {
        "dataparallel": {
            "enabled": True,
            "custom_mpi_options": "-verbose -x NCCL_DEBUG=VERSION"
        }
    }
}

```

**`train_instance_type (str)(required)`**: A type of Amazon EC2 instance to use.

- If the `smdistributed.dataparallel` distribution strategy is used, the allowed instance types are: `ml.p4d.24xlarge`, `ml.p3dn.24xlarge`, and `ml.p3.16xlarge`. For best performance, it is recommended that you use an EFA supported instance, `ml.p3dn.24xlarge` or `ml.p4d.24xlarge`, with the latest supported version of PyTorch.

### Example

```

from sagemaker.pytorch import PyTorch
pt_estimator = PyTorch(
    base_job_name="training_job_name_prefix",
    entry_point="pt-train.py",
    role="SageMakerRole",
    # You must set py_version to py36
    py_version="py36",
    framework_version="1.8.1",
    # For training with multi node distributed training, set this count.
    # Example: 2,3,4,..8
    instance_count=2,
    # For training with p3dn instance use - ml.p3dn.24xlarge
    instance_type="ml.p3.16xlarge",
    # Training using smdistributed.dataparallel Distributed Training Framework
    distribution={"smdistributed": {"dataparallel": {"enabled": True}}})
)

pt_estimator.fit("s3://bucket/path/to/training/data")

```

### Note

If you are using SageMaker Python SDK 1.x, you need to use hyperparameters to specify `smdistributed.dataparallel` as the distributed training strategy.

```

from sagemaker.pytorch import PyTorch
pt_estimator = PyTorch(
    ...
    # Training using smdistributed.dataparallel Distributed
    Training Framework

    hyperparameters={"sagemaker_distributed_dataparallel_enabled": True},
    ...
)
pt_estimator.fit("s3://bucket/path/to/training/data")

```

# Modify Your Training Script using the SageMaker Data Parallel Library

## Script Modification Overview

SageMaker's distributed data parallel library (the library) APIs are designed for ease of use, and to provide seamless integration with existing distributed training toolkits.

- *SageMaker Python SDK with the library API:* In most cases, all you have to change in your training script is the Horovod or other data parallel library import statements. Swap these out with the SageMaker data parallel library equivalents.
- *Focus on your model training without infrastructure management:* When training a deep learning model with the library on SageMaker, you can focus on your model training, while SageMaker does cluster management: brings up the nodes and creates the cluster, completes the training, then tears down the cluster.

To customize your own training script, you need to do the following:

- You must provide TensorFlow/PyTorch training scripts that are adapted to use the library. The following sections provide example code for this.
- Your input data must be in an S3 bucket or in FSx in the Amazon Region that you will use to launch your training job. If you use the Jupyter Notebooks provided, create a SageMaker notebook instance in the same Region as the bucket that contains your input data. For more information about storing your training data, refer to the [SageMaker Python SDK data inputs](#) documentation.

### Tip

Consider using FSx instead of Amazon S3 to increase training performance. It has higher throughput and lower latency than Amazon S3.

Use the following sections to see examples of training scripts that can be used to convert your TensorFlow or PyTorch training scripts. Then, use one of the example notebooks for your template to launch a training job. You'll need to swap your training script with the one that came with the notebook and modify any input functions as necessary. Once you have launched a training job, you can monitor it using Amazon CloudWatch.

Then you can see how to deploy your trained model to an endpoint by following one of the example notebooks for deploying a model.

Finally, you can follow an example notebook to test inference on your deployed model.

## Modify a TensorFlow 2.x Training Script Using SageMaker Distributed Data Parallel

The following steps show you how to convert a TensorFlow 2.3.1 or 2.4.1 training script to utilize SageMaker's distributed data parallel library.

The library APIs are designed to be similar to Horovod APIs. Refer to the [SageMaker distributed data parallel TensorFlow API documentation](#) for additional details on each API that the library offers for TensorFlow.

### Note

SageMaker distributed data parallel is adaptable to TensorFlow training scripts composed of `tf` core modules except `tf.keras` modules. SageMaker distributed data parallel does not support TensorFlow with Keras implementation.

1. Import the library's TensorFlow client and initialize it:

```
import smdistributed.dataparallel.tensorflow as sdp
sdp.init()
```

2. Pin each GPU to a single `smdistributed.dataparallel` process with `local_rank`—this refers to the relative rank of the process within a given node. The `sdp.tensorflow.local_rank()` API provides you the local rank of the device. The leader node is rank 0, and the worker nodes are rank 1, 2, 3, and so on. This is invoked in the next code block as `sdp.local_rank()`. `set_memory_growth` is not directly related to SageMaker distributed, but must be set for distributed training with TensorFlow.

```
gpus = tf.config.experimental.list_physical_devices('GPU')
for gpu in gpus:
    tf.config.experimental.set_memory_growth(gpu, True)
if gpus:
    tf.config.experimental.set_visible_devices(gpus[sdp.local_rank()], 'GPU')
```

3. Scale the learning rate by the number of workers. The `sdp.tensorflow.size()` API provides you the number of workers in the cluster. This is invoked in the next code block as `sdp.size()`.

```
learning_rate = learning_rate * sdp.size()
```

4. Use the library's `DistributedGradientTape` to optimize AllReduce operations during training. This wraps `tf.GradientTape`.

```
with tf.GradientTape() as tape:
    output = model(input)
    loss_value = loss(label, output)

# SageMaker data parallel: Wrap tf.GradientTape with the library's
# DistributedGradientTape
tape = sdp.DistributedGradientTape(tape)
```

5. Broadcast the initial model variables from the leader node (rank 0) to all the worker nodes (ranks 1 through n). This is needed to ensure a consistent initialization across all the worker ranks. For this, you use the `sdp.tensorflow.broadcast_variables` API after the model and optimizer variables are initialized. This is invoked in the next code block as `sdp.broadcast_variables()`.

```
sdp.broadcast_variables(model.variables, root_rank=0)
sdp.broadcast_variables(opt.variables(), root_rank=0)
```

6. Finally, modify your script to save checkpoints only on the leader node. The leader node has a synchronized model. This also avoids worker nodes overwriting the checkpoints and possibly corrupting the checkpoints.

```
if sdp.rank() == 0:
    checkpoint.save(checkpoint_dir)
```

The following is an example TensorFlow2 training script for distributed training with the library:

```
import tensorflow as tf

# SageMaker data parallel: Import the library TF API
import smdistributed.dataparallel.tensorflow as sdp

# SageMaker data parallel: Initialize the library
sdp.init()
```

```

gpus = tf.config.experimental.list_physical_devices('GPU')
for gpu in gpus:
    tf.config.experimental.set_memory_growth(gpu, True)
if gpus:
    # SageMaker data parallel: Pin GPUs to a single library process
    tf.config.experimental.set_visible_devices(gpus[sdp.local_rank()], 'GPU')

# Prepare Dataset
dataset = tf.data.Dataset.from_tensor_slices(...)

# Define Model
mnist_model = tf.keras.Sequential(...)
loss = tf.losses.SparseCategoricalCrossentropy()

# SageMaker data parallel: Scale Learning Rate
# LR for 8 node run : 0.000125
# LR for single node run : 0.001
opt = tf.optimizers.Adam(0.000125 * sdp.size())

@tf.function
def training_step(images, labels, first_batch):
    with tf.GradientTape() as tape:
        probs = mnist_model(images, training=True)
        loss_value = loss(labels, probs)

    # SageMaker data parallel: Wrap tf.GradientTape with the library's
    # DistributedGradientTape
    tape = sdp.DistributedGradientTape(tape)

    grads = tape.gradient(loss_value, mnist_model.trainable_variables)
    opt.apply_gradients(zip(grads, mnist_model.trainable_variables))

    if first_batch:
        # SageMaker data parallel: Broadcast model and optimizer variables
        sdp.broadcast_variables(mnist_model.variables, root_rank=0)
        sdp.broadcast_variables(opt.variables(), root_rank=0)

    return loss_value

...
# SageMaker data parallel: Save checkpoints only from master node.
if sdp.rank() == 0:
    checkpoint.save(checkpoint_dir)

```

For more advanced usage, refer to [SageMaker Distributed Data Parallel TensorFlow API documentation](#).

## Modify a PyTorch Training Script Using SMD Data Parallel

The following steps show you how to convert a PyTorch training script to utilize SageMaker's distributed data parallel library.

The library APIs are designed to be similar to PyTorch Distributed Data Parallel (DDP) APIs. For additional details on each data parallel API offered for PyTorch, see the [SageMaker distributed data parallel PyTorch API documentation](#).

1. Import the library's PyTorch client and initialize it, then import the module for distributed training.

```

import smdistributed.dataparallel.torch.distributed as dist

from smdistributed.dataparallel.torch.parallel.distributed import
    DistributedDataParallel as DDP

```

```
dist.init_process_group()
```

2. After parsing arguments and defining a batch size parameter (for example, `batch_size=args.batch_size`), add a 2-line of code to resize the batch size per worker (GPU). PyTorch's `DataLoader` operation does not automatically handle the batch resizing for distributed training.

```
batch_size // dist.get_world_size()  
batch_size = max(batch_size, 1)
```

3. Pin each GPU to a single SageMaker data parallel library process with `local_rank`—this refers to the relative rank of the process within a given node.

The `smdistributed.dataparallel.torch.get_local_rank()` API provides you the local rank of the device. The leader node is rank 0, and the worker nodes are rank 1, 2, 3, and so on. This is invoked in the next code block as `dist.get_local_rank()`.

```
torch.cuda.set_device(dist.get_local_rank())
```

4. Wrap the PyTorch model with the library's DDP.

```
model = ...  
# Wrap model with the library's DistributedDataParallel  
model = DDP(model)
```

5. Modify the `torch.utils.data.distributed.DistributedSampler` to include the cluster's information. Set `num_replicas` to the total number of GPUs participating in training across all the nodes in the cluster. This is called `world_size`. You can get `world_size` with the `smdistributed.dataparallel.torch.get_world_size()` API. This is invoked in the following code as `dist.get_world_size()`. Also supply the node rank using `smdistributed.dataparallel.torch.get_rank()`. This is invoked as `dist.get_rank()`.

```
train_sampler = DistributedSampler(train_dataset, num_replicas=dist.get_world_size(),  
rank=dist.get_rank())
```

6. Modify your script to save checkpoints only on the leader node. The leader node has a synchronized model. This also avoids worker nodes overwriting the checkpoints and possibly corrupting the checkpoints.

The following is an example PyTorch training script for distributed training with the library:

```
# SageMaker data parallel: Import the library PyTorch API  
import smdistributed.dataparallel.torch.distributed as dist  
  
# SageMaker data parallel: Import the library PyTorch DDP  
from smdistributed.dataparallel.torch.parallel.distributed import DistributedDataParallel  
as DDP  
  
# SageMaker data parallel: Initialize the library  
dist.init_process_group()  
  
class Net(nn.Module):  
    ...  
    # Define model  
  
def train(...):  
    ...  
    # Model training
```

```
def test(...):
    ...
    # Model evaluation

def main():

    # SageMaker data parallel: Scale batch size by world size
    batch_size // dist.get_world_size()
    batch_size = max(batch_size, 1)

    # Prepare dataset
    train_dataset = torchvision.datasets.MNIST(...)

    # SageMaker data parallel: Set num_replicas and rank in DistributedSampler
    train_sampler = torch.utils.data.distributed.DistributedSampler(
        train_dataset,
        num_replicas=dist.get_world_size(),
        rank=dist.get_rank())

    train_loader = torch.utils.data.DataLoader(...)

    # SageMaker data parallel: Wrap the PyTorch model with the library's DDP
    model = DDP(Net().to(device))

    # SageMaker data parallel: Pin each GPU to a single library process.
    torch.cuda.set_device(local_rank)
    model.cuda(local_rank)

    # Train
    optimizer = optim.Adadelta(...)
    scheduler = StepLR(...)
    for epoch in range(1, args.epochs + 1):
        train(...)
        if rank == 0:
            test(...)
        scheduler.step()

    # SageMaker data parallel: Save model on master node.
    if dist.get_rank() == 0:
        torch.save(...)

if __name__ == '__main__':
    main()
```

For more advanced usage, see the [SageMaker distributed data parallel PyTorch API documentation](#).

## Launch a Training Job

To launch the training job using your SageMaker distributed data parallel configured training script, you use the `Estimator.fit()` function. We recommend that you launch a training job using a SageMaker notebook instance or SageMaker Studio. To see an example of how you can launch a training job using a Studio or a notebook instance, see [Distributed Training Jupyter Notebook Examples \(p. 1819\)](#).

Use the following resources to learn more about using the SageMaker Python SDK with these frameworks:

- [Use TensorFlow with the SageMaker Python SDK](#)
- [Using PyTorch with the SageMaker Python SDK](#)

## SageMaker distributed data parallel Configuration Tips and Pitfalls

Review the following tips and pitfalls before using SageMaker's distributed data parallel library. This list includes tips that are applicable across frameworks.

### Topics

- [Data Preprocessing \(p. 1792\)](#)
- [Single vs Multiple Nodes \(p. 1792\)](#)
- [Debug Scaling Efficiency with Debugger \(p. 1792\)](#)
- [Batch Size \(p. 1792\)](#)
- [Custom MPI Options \(p. 1793\)](#)

### Data Preprocessing

If you pre-process data during training using an external library that utilizes the CPU, you may run into a CPU bottleneck because SageMaker distributed data parallel uses the CPU for all-reduce operations. You may be able to improve training time by moving pre-processing steps to a library that uses GPUs or by completing all pre-processing before training.

### Single vs Multiple Nodes

It is recommended that you use this library with multiple nodes. The library can be used with a single-host, multi-device setup (for example, a single ML compute instance with multiple GPUs), however, when you use two or more nodes, the library's AllReduce operation gives you significant performance improvement. Also, on a single host, NVLink already contributes to in-node AllReduce efficiency.

### Debug Scaling Efficiency with Debugger

You can use Amazon SageMaker Debugger to monitor and visualize CPU and GPU utilization, and other metrics of interest, during training. You can use Debugger [built-in rules](#) to monitor computational performance issues, such as CPUBottleneck, LoadBalancing, and LowGPUUtilization. You can specify these rules with [Debugger configurations](#) when you define an Amazon SageMaker Python SDK estimator. If you use Amazon CLI and Amazon Boto3 for training on SageMaker, you can enable Debugger as shown in [Configure Debugger Using Amazon SageMaker API](#).

To see an example using Debugger in a SageMaker training job, you can reference one of the notebook example in the [SageMaker Notebook Examples GitHub repository](#). To learn more about Debugger, see [Amazon SageMaker Debugger](#).

### Batch Size

In distributed training, as more nodes are added, batch sizes should increase proportionally. To improve convergence speed as you add more nodes to your training job and increase the global batch size, increase the learning rate.

One way to achieve this is by using a gradual learning rate warmup where the learning rate is ramped up from a small to a large value as the training job progresses. This ramp avoids a sudden increase of the learning rate, allowing healthy convergence at the start of training. For example, you can use a "Linear Scaling Rule" where each time the mini-batch size is multiplied by k, the learning rate is also multiplied by k. To learn more about this technique, see the research paper, Accurate, [Large Minibatch SGD: Training ImageNet in 1 Hour](#), Sections 2 and 3.

## Custom MPI Options

The SageMaker distributed data parallel library employs Message Passing Interface (MPI), a popular standard for managing communication between nodes in a high-performance cluster, and uses NVIDIA's NCCL library for GPU-level communication. When you use the data parallel library with a TensorFlow or Pytorch Estimator, the respective container sets up the MPI environment and executes the `mpirun` command to start jobs on the cluster nodes.

You can set custom MPI operations using the `custom_mpi_options` parameter in the `Estimator`. Any `mpirun` flags passed in this field are added to the `mpirun` command and executed by Amazon SageMaker for training. For example, you may define the `distribution` parameter of an `Estimator` using the following to use the `NCCL_DEBUG` variable to print the NCCL version at the start of the program:

```
distribution = {'smdistributed': {'dataparallel': {'enabled': True, "custom_mpi_options": "-verbose -x NCCL_DEBUG=VERSION"}}}
```

## Data Parallel Library FAQ

Use the following to find answers to commonly asked questions about SageMaker's data parallelism library.

**Q: When using the library, how are the allreduce-supporting CPU instances managed? Do I have to create heterogeneous CPU-GPU clusters, or does the SageMaker service create extra C5s for jobs that use the library?**

The library uses the CPUs available with GPU instances. No additional C5 or CPU instances are launched; if your SageMaker training job is 8 node `m1.p3dn.24xlarge` clusters, only 8 `m1.p3dn.24xlarge` instances are used. No additional instances are provisioned.

**Q: I have a training job taking 5 days on a single `m1.p3.24xlarge` instance with a set of hyperparameters H1 (learning rate, batch size, optimizer, etc). Is enabling SDP and using a 5x bigger cluster enough to experience an approximate 5x speedup? Or will I have to revisit its training hyperparameters after enabling SDP?**

Enabling the library would change the overall batch size. The new overall batch size is scaled linearly with the number of training instances used. As a result of this, hyperparameters, such as learning rate, have to be changed to ensure convergence.

**Q: Does the library support Spot?**

Yes. You can use managed spot training. You specify the path to the checkpoint file in the SageMaker training job. You enable save/restore checkpoints in their training script as mentioned in the last step of the section called "Script Modification Overview" (p. 1787).

**Q: What is the difference between the library's balanced fusion buffers and PyTorch Distributed Data Parallel (DDP) "Gradient Buckets"?**

The primary difference is that DDP's fusion buffer is used for AllReduce and the library's balanced fusion buffer is used for parameter server style synchronization. The library is the first framework to shard fusion buffers in parameter server-based gradient synchronization.

From the [PyTorch DDP documentation](#): "To improve communication efficiency, the Reducer organizes parameter gradients into buckets, and reduces one bucket at a time. Bucket size can be configured by setting the `bucket_cap_mb` argument in DDP constructor. The mapping from parameter gradients to buckets is determined at the construction time, based on the bucket size limit and parameter sizes. Model parameters are allocated into buckets in (roughly) the reverse order of `Model.parameters()`

from the given model. The reason for using the reverse order is because DDP expects gradients to become ready during the backward pass in approximately that order.”

**Q: Is the library relevant in single-host, multi-device setup?**

The library can be used with a single-host, multi-device setup. However, in two or more nodes, the library’s AllReduce operation gives you significant performance improvement. Also, on a single host, NVLink already contributes to in-node AllReduce efficiency.

**Q: Can the library be used with PyTorch Lightning?**

No. However, with the library’s DDP for PyTorch, you can write custom DDP to achieve the functionality.

**Q: Where should the training dataset be stored?**

The training dataset can be stored in an S3 bucket or on an FSx drive. See this [document for various supported input filesystem for a training job](#).

**Q: When using the library, is it mandatory to have training data in FSx for Lustre? Can EFS and S3 be used?**

We recommend using FSx to cut down the time to kickstart the training. It is not mandatory.

**Q: Can the library be used with CPU nodes?**

No. The library supports m1.p3.16xlarge, m1.p3dn.24xlarge, and m1.p4d.24xlarge instances at this time.

**Q: What frameworks and framework versions are currently supported by the library at launch?**

The library currently supports PyTorch v1.6.0 or later and Tensorflow v2.3.0 or later. It doesn’t support Tensorflow 1.x. For more information about which version of the library is packaged within Amazon deep learning containers, see [Release Notes for Deep Learning Containers](#).

## Data Parallel Troubleshooting

If you run into an error, you can use the following list to try to troubleshoot your training job. If the problem persists, contact Amazon Support.

**Topics**

- [Considerations for Using SageMaker Distributed Data Parallel with SageMaker Debugger and Checkpoints \(p. 1794\)](#)
- [An Unexpected Prefix \(model for example\) Is Attached to state\\_dict keys \(model parameters\) from a PyTorch Distributed Training Job \(p. 1795\)](#)

### Considerations for Using SageMaker Distributed Data Parallel with SageMaker Debugger and Checkpoints

To monitor system bottlenecks, profile framework operations, and debug model output tensors for training jobs with SageMaker distributed data parallel, you use SageMaker Debugger.

However, when you use SageMaker Debugger, SageMaker distributed data parallel, and SageMaker checkpoints, you might see an error that looks like the following:

SMD-debug Does Not Currently Support Distributed Training Jobs With Checkpointing Enabled

This is due to an internal error between Debugger and checkpoints, which occurs when you enable SageMaker Distributed.

- If you enable all three features, SageMaker Python SDK automatically turns off Debugger by passing `debugger_hook_config=False`, which is equivalent to the following framework estimator example.

```
bucket=sagemaker.Session().default_bucket()
base_job_name="sagemaker-checkpoint-test"
checkpoint_in_bucket="checkpoints"

# The S3 URI to store the checkpoints
checkpoint_s3_bucket="s3://{}//{}/{}".format(bucket, base_job_name, checkpoint_in_bucket)

estimator = TensorFlow(
    ...
    distribution={"smdistributed": {"dataparallel": { "enabled": True }}},
    checkpoint_s3_uri=checkpoint_s3_bucket,
    checkpoint_local_path="/opt/ml/checkpoints",
    debugger_hook_config=False
)
```

- If you want to keep using both SageMaker distributed data parallel and SageMaker Debugger, a workaround is manually adding checkpointing functions to your training script instead of specifying the `checkpoint_s3_uri` and `checkpoint_local_path` parameters from the estimator. For more information about setting up manual checkpointing in a training script, see [Saving Checkpoints \(p. 1818\)](#).

## An Unexpected Prefix (`model` for example) Is Attached to `state_dict` keys (model parameters) from a PyTorch Distributed Training Job

The SageMaker data parallel library does not directly alter or prepend any model parameter names when PyTorch training jobs save model artifacts. The PyTorch's distributed training changes the names in the `state_dict` to go over the network, prepending the prefix. If you encounter any model failure problem due to the different parameter names while you are using the SageMaker data parallel library and checkpointing for PyTorch training, adapt the following example code to remove the prefix at the step you load checkpoints in your training script:

```
state_dict = {k.partition('model.')[2]:state_dict[k] for k in state_dict.keys()}
```

This takes each `state_dict` key as a string value, separates the string at the first occurrence of '`model.`', and takes the third list item (with index 2) of the partitioned string.

For more information about the prefix issue, see a discussion thread at [Prefix parameter names in saved model if trained by multi-GPU?](#) in the *PyTorch discussion forum*.

For more information about the PyTorch methods for saving and loading models, see [Saving & Loading Model Across Devices](#) in the *PyTorch documentation*.

## SageMaker's Distributed Model Parallel

### Important

To use new features with an existing notebook instance or Studio app, restart it to get the latest updates.

Amazon SageMaker's distributed model parallel library (the library) can be used to train large deep learning models that were previously difficult to train due to GPU memory limitations. The library automatically and efficiently splits a model across multiple GPUs and instances and coordinates model training, allowing you to increase prediction accuracy by creating larger models with more parameters.

You can use the library to automatically partition your existing TensorFlow and PyTorch workloads across multiple GPUs with minimal code changes. You can access the library's API through the SageMaker SDK.

Use the following sections to learn more about model parallelism and the SageMaker model parallel library. This library's API documentation is located in the SageMaker Python SDK under [Distributed Training APIs](#). To see the latest updates to the library, refer to the [release notes](#).

## Introduction to Model Parallelism

**Model parallelism** is the process of splitting a model up between multiple devices or nodes (such as GPU-equipped instances) and creating an efficient pipeline to train the model across these devices to maximize GPU utilization.

Use the sections on this page to learn more about model parallelism, including how it can be used to overcome issues that arise when training large ML models, and important considerations when integrating it into your ML training script.

### What is Model Parallelism?

Increasing deep learning model size (layers and parameters) can result in better accuracy, however there is a limit to the maximum model size you can fit in a single GPU. When training deep learning models, GPU memory limitations can be a bottleneck in the following ways:

- They can limit the size of the model you train. Given that larger models tend to achieve higher accuracy, this directly translates to trained model accuracy.
- They can limit the batch size you train with, leading to lower GPU utilization and slower training.

To overcome the limitations associated with training a model on a single GPU, you can use model parallelism to distribute and train your model on multiple computing devices.

### Important Considerations when Using Model Parallelism

When you use model parallelism, you must consider the following:

- **How you split your model across devices** : The computational graph of your model, sizes of model parameters and activations, and your resource constraints (for example, time vs. memory) determine the best partitioning strategy.

To reduce the time and effort required to efficiently split your model, you can use automated model splitting features offered by Amazon SageMaker's distributed model parallel library.

- **Achieving parallelization** : Model training—that is, forward computations and backward propagation—is inherently sequential, where each operation must wait for its inputs to be computed by another operation. For this reason, forward and backward pass stages of deep learning training are not easily parallelizable, and naively splitting a model across multiple GPUs may lead to poor device utilization. For example, a layer on GPU  $i+1$  has to wait for the output from a layer on GPU  $i$ , and so GPU  $i+1$  remains idle during this waiting period.

The model parallel library can achieve true parallelization by implementing pipelined execution by building an efficient computation schedule where different devices can work on forward and backward passes for different data samples at the same time.

To learn how you can use the library to efficiently split your model across devices and improve device utilization during training, see [Core Features of SageMaker Distributed Model Parallel \(p. 1797\)](#).

## Core Features of SageMaker Distributed Model Parallel

Amazon SageMaker's distributed model parallel makes model parallelism more accessible by providing automated model splitting and sophisticated pipeline execution scheduling. The model splitting algorithms can optimize for speed or memory consumption. The library also supports manual partitioning. When you use the library, training is executed in a pipelined fashion over microbatches to maximize GPU usage.

You can configure these features using a few lines of code when you create your training script and define your SageMaker PyTorch or Tensorflow Estimator. Use the following sections to learn more about these core features of the library.

### Automated Model Splitting

When you use SageMaker's model parallel library, you can take advantage of *automated model splitting*, also referred to as *automated model partitioning*. The library uses a partitioning algorithm that balances memory, minimizes communication between devices, and optimizes performance. You can configure the automated partitioning algorithm to optimize for speed or memory.

Alternatively, you can use manual model splitting. We recommend automated model splitting, unless you are very familiar with the model architecture and have a good idea of how to efficiently partition your model.

### How It Works

Auto-partitioning occurs during the first training step, when the `smp.step`-decorated function is first called. During this call, the library first constructs a version of the model on the CPU RAM (to avoid GPU memory limitations), and then analyzes the model graph and makes a partitioning decision. Based on this decision, each model partition is loaded on a GPU, and only then the first step is executed. Because of these analysis and partitioning steps, the first training step might take longer.

In either framework, the library manages the communication between devices through its own backend, which is optimized for Amazon infrastructure.

The auto-partition design adapts to the characteristics of the framework, and the library does the partitioning at the granularity level that is more natural in each framework. For instance, in TensorFlow, each specific operation can be assigned to a different device, whereas in PyTorch, the assignment is done at the module level, where each module consists of multiple operations. The follow section reviews the specifics of the design in each framework.

### Automated Model Splitting with PyTorch

During the first training step, the model parallel library internally runs a tracing step that is meant to construct the model graph and determine the tensor and parameter shapes. After this tracing step, the library constructs a tree, which consists of the nested `nn.Module` objects in the model, as well as additional data gathered from tracing, such as the amount of stored `nn.Parameters`, and execution time for each `nn.Module`.

Next, the library traverses this tree from the root and runs a partitioning algorithm that assigns each `nn.Module` to a device, which balances computational load (measured by module execution time) and memory use (measured by the total stored `nn.Parameter` size and activations). If multiple `nn.Modules`

share the same `nn.Parameter`, then these modules are placed on the same device to avoid maintaining multiple versions of the same parameter. Once the partitioning decision is made, the assigned modules and weights are loaded to their devices.

### Automated Model Splitting with TensorFlow

The model parallel library analyzes the sizes of the trainable variables and the graph structure, and internally uses a graph partitioning algorithm. This algorithm comes up with a device assignment for each operation, with the objective of minimizing the amount of communication needed across devices, subject to two constraints:

- Balancing the number of variables stored in each device
- Balancing the number of operations executed in each device

If you specify `speed` for `optimize` (in the model parallel parameters in the Python SDK), the library tries to balance the number of operations and `tf.Variable` objects in each device. Otherwise, it tries to balance the total size of `tf.Variables`.

Once the partitioning decision is made, the library creates a serialized representation of the subgraph that each device needs to execute and imports them onto each device. While partitioning, the library places operations that consume the same `tf.Variable` and operations that are part of the same Keras layer onto the same device. It also respects the colocation constraints imposed by TensorFlow. This means that, for example, if there are two Keras layers that share a `tf.Variable`, then all operations that are part of these layers are placed on a single device.

### Comparison of Automated Model Splitting Between Frameworks

In TensorFlow, the fundamental unit of computation is a `tf.Operation`, and TensorFlow represents the model as a directed acyclic graph (DAG) of `tf.Operations`, and therefore model parallel library partitions this DAG so that each node goes to one device. Crucially, `tf.Operation` objects are sufficiently rich with customizable attributes, and they are universal in the sense that every model is guaranteed to consist of a graph of such objects.

PyTorch on the other hand, does not have an equivalent notion of operation that is sufficiently rich and universal. The closest unit of computation in PyTorch that has these characteristics is an `nn.Module`, which is at a much higher granularity level, and this is why the library does partitioning at this level in PyTorch.

### Manual Model Splitting

If you want to manually specify how your model is partitioned across devices, you can use manual model splitting by using `smp.partition` context managers.

To use this option, set `auto_partition` to `False`, and define a `default_partition` in the SageMaker Python SDK. Any operation that is not explicitly placed on a partition through the `smp.partition` context manager is executed on the `default_partition`. In this case, the automated splitting logic is bypassed, and each operation is placed based on your specification. Based on the resulting graph structure, the model parallel library creates a pipelined execution schedule automatically.

### Pipeline Execution Schedule

A core feature of SageMaker's distributed model parallel library is *pipelined execution*, which determines the order in which computations are made and data is processed across devices during model training. Pipelining is a technique to achieve true parallelization in model parallelism, by having the GPUs compute simultaneously on different data samples, and to overcome the performance loss due to sequential computation.

Pipelining is based on splitting a mini-batch into microbatches, which are fed into the training pipeline one-by-one and follow an execution schedule defined by the library runtime. A *microbatch* is a smaller

subset of a given training mini-batch. The pipeline schedule determines which microbatch is executed by which device for every time slot.

For example, depending on the pipeline schedule and the model partition, GPU  $i$  might perform (forward or backward) computation on microbatch  $b$  while GPU  $i+1$  performs computation on microbatch  $b+1$ , thereby keeping both GPUs active at the same time. During a single forward or backward pass, execution flow for a single microbatch might visit the same device multiple times, depending on the partitioning decision. For instance, an operation that is at the beginning of the model might be placed on the same device as an operation at the end of the model, while the operations in between are on different devices, which means this device is visited twice.

The library offers two different pipeline schedules, *simple* and *interleaved*, which can be configured using the `pipeline` parameter in the SageMaker Python SDK. In most cases, interleaved pipeline can achieve better performance by utilizing the GPUs more efficiently.

### Interleaved Pipeline

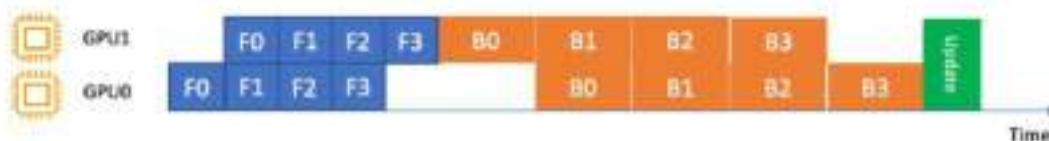

In an interleaved pipeline, backward execution of the microbatches is prioritized whenever possible. This allows quicker release of the memory used for activations, using memory more efficiently. It also allows for scaling the number of microbatches higher, reducing the idle time of the GPUs. At steady-state, each device alternates between running forward and backward passes. This means that the backward pass of one microbatch may run before the forward pass of another microbatch finishes.

The preceding figure illustrates an example execution schedule for the interleaved pipeline over 2 GPUs. In the figure, F0 represents the forward pass for microbatch 0, and B1 represents the backward pass for microbatch 1. **Update** represents the optimizer update of the parameters. GPU0 always prioritizes backward passes whenever possible (for instance, executes B0 before F2), which allows for clearing of the memory used for activations earlier.

### Simple Pipeline

A simple pipeline, by contrast, finishes running the forward pass for each microbatch before starting the backward pass. This means that it only pipelines the forward pass and backward pass stages within themselves. The following figure illustrates an example of how this works, over 2 GPUs.

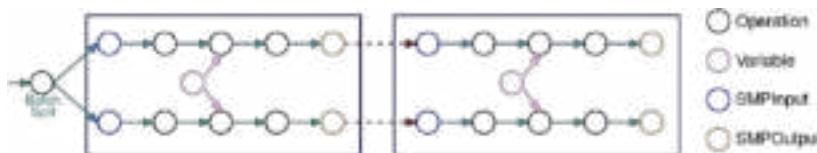

### Pipelining Execution in Specific Frameworks

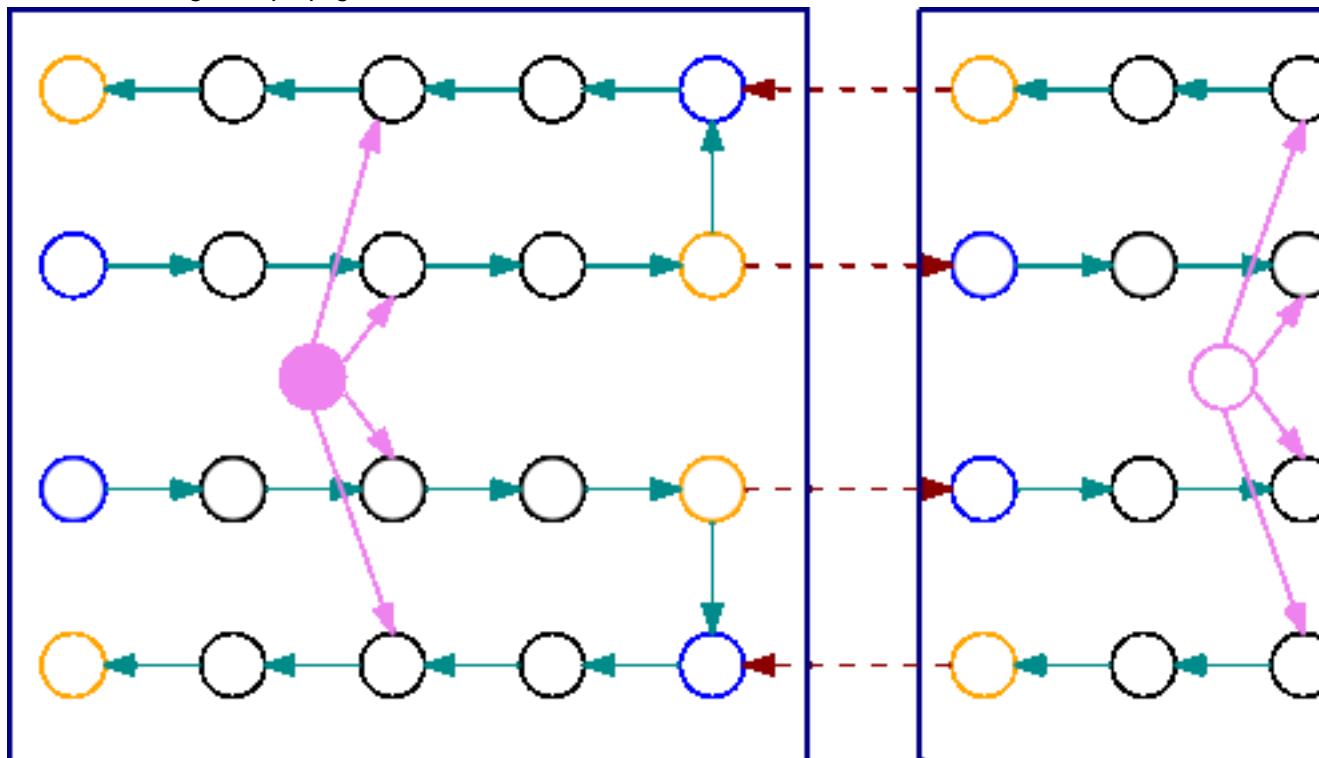

Use the following sections to learn about the framework-specific pipeline scheduling decisions SageMaker's distributed model parallel library makes for Tensorflow and PyTorch.

#### Pipeline Execution with TensorFlow

The following image is an example of a TensorFlow graph partitioned by the model parallel library, using automated model splitting. When a graph is split, each resulting subgraph is replicated  $B$  times (except for the variables), where  $B$  is the number of microbatches. In this figure, each subgraph is replicated 2 times ( $B=2$ ). An `SMPInput` operation is inserted at each input of a subgraph, and an `SMPOutput` operation is inserted at each output. These operations communicate with the library backend to transfer tensors to and from each other.

The following image is an example of 2 subgraphs split with  $B=2$  with gradient operations added. The gradient of a **SMPInput** op is a **SMPOutput** op, and vice versa. This enables the gradients to flow backwards during back-propagation.

This GIF demonstrates an example interleaved pipeline execution schedule with  $B=2$  microbatches and 2 subgraphs. Each device sequentially executes one of the subgraph replicas to improve GPU utilization. As  $B$  grows larger, the fraction of idle time slots goes to zero. Whenever it is time to do (forward or backward) computation on a specific subgraph replica, the pipeline layer signals to the corresponding blue **SMPInput** operations to start executing.

Once the gradients from all microbatches in a single mini-batch are computed, the library combines the gradients across microbatches, which can then be applied to the parameters.

### Pipeline Execution with PyTorch

Conceptually, pipelining follows a similar idea in PyTorch. However, since PyTorch does not involve static graphs and so the model parallel library's PyTorch feature uses a more dynamic pipelining paradigm.

As in TensorFlow, each batch is split into a number of microbatches, which are executed one at a time on each device. However, the execution schedule is handled via execution servers launched on each device. Whenever the output of a submodule that is placed on another device is needed on the current device, an execution request is sent to the execution server of the remote device along with the input tensors to the submodule. The server then executes this module with the given inputs and returns the response to the current device.

Since the current device is idle during the remote submodule execution, the local execution for the current microbatch pauses, and the library runtime switches execution to another microbatch which the current device can actively work on. The prioritization of microbatches is determined by the chosen pipeline schedule. For an interleaved pipeline schedule, microbatches that are in the backward stage of the computation are prioritized whenever possible.

## Use the SageMaker Distributed Model Parallel API

To use Amazon SageMaker's distributed model parallel library, you must create a training script for one of the supported frameworks and launch the training job using the SageMaker Python SDK. To learn how you can incorporate the library into a training script, see [Modify Your Training Script Using SageMaker's Distributed Model Parallel Library \(p. 1804\)](#). The library's API documentation is located in the SageMaker Python SDK. Refer to the [SageMaker's distributed model parallel API documentation](#).

SageMaker supports the following training environment configurations.

1. You can use a prebuilt TensorFlow or PyTorch container. This option is recommended for new users of the model parallel library, and is demonstrated in the example [MNIST with PyTorch 1.6 and Amazon SageMaker's distributed model parallel library](#).
2. You can extend SageMaker prebuilt containers to handle any additional functional requirements for your algorithm or model that the prebuilt SageMaker Docker image doesn't support. To see an example of how you can extend a pre-built container, see [Extend a Prebuilt Container](#).
3. You can adapt your own Docker container to work with SageMaker using the [SageMaker Training toolkit](#). For an example, see [Adapting Your Own Training Container](#).

For options 2 and 3 in the preceding list, refer to [Extend or Adapt A Docker Container that Contains SageMaker's Distributed Model Parallel Library \(p. 1803\)](#) to learn how to install the model parallel library in an extended or customized Docker container.

In all cases, you launch your job using a SageMaker Python SDK TensorFlow or PyTorch `Estimator` to initialize the library and launch a training job. See the following section, [Launch a Training Job with the SageMaker Python SDK \(p. 1801\)](#), to learn more.

**Important**

If you launch a training job using an `ml.p4d` instance type (such as `ml.p4d.24xlarge`), for best performance set the following flags in the `mpirun` command. If you use one of these flags, you *must* use the other.

```
-x FI_EFA_USE_DEVICE_RDMA=1 -x FI_PROVIDER=efa
```

Additionally, if you are using PyTorch, you must set the data loader variable `num_workers=0`. To Learn more about the data loader requirement, see [Important Considerations \(p. 1810\)](#).

## Launch a Training Job with the SageMaker Python SDK

The SageMaker Python SDK supports managed training of TensorFlow and PyTorch models. To launch a training job using one of these frameworks, you can define a `TensorFlow Estimator` or a `PyTorch Estimator`.

The TensorFlow and PyTorch `Estimator` object contains a `distribution` parameter, which is used to enable and specify parameters for the initialization of SageMaker's distributed model parallel library. The library internally uses MPI, so in order to use model parallelism, MPI must be enabled using the `distribution` parameter.

The following is an example of how you can launch a new PyTorch training job with the library.

```
sagemaker_session = sagemaker.session.Session(boto_session=session)

mpi_options = {
    "enabled" : True,
    "processes_per_host" : 8,
    "custom_mpi_options" : "--mca btl_vader_single_copy_mechanism none "
}

smp_options = {
    "enabled":True,
    "parameters": {
        "microbatches": 4,
        "placement_strategy": "spread",
        "pipeline": "interleaved",
        "optimize": "speed",
        "partitions": 2,
        "ddp": True,
    }
}

smd_mp_estimator = PyTorch(
    entry_point="pt_mnist.py", # Pick your train script
    source_dir='utils',
    role=role,
    instance_type='ml.p3.16xlarge',
    sagemaker_session=sagemaker_session,
    framework_version='1.6.0',
    # You must set py_version to py36
    py_version='py36',
    instance_count=1,
    distribution={
        "smdistributed": {"modelparallel": smp_options},
        "mpi": mpi_options
    },
    base_job_name="SMD-MP-demo",
)
smd_mp_estimator.fit('s3://my_bucket/my_training_data/')
```

To enable the library, a dictionary with the keys "`mpi`" and "`smdistributed`" needs to be passed as the `distribution` argument of the TensorFlow and PyTorch `Estimator` constructors in Python SDK. For the "`mpi`" key, a dict must be passed which contains:

- "`enabled`": `True` to launch the training job with MPI.
- "`processes_per_hostAmazon EC2 ml instance. The SageMaker Python SDK maintains a one-to-one mapping between processes and GPUs across model and data parallelism. This means that SageMaker schedules each process on a single, separate GPU and no GPU contains more than one process. If you are using PyTorch, you must restrict each process to its own device through torch.cuda.set_device(smp.local_rank()). To learn more, see PyTorch \(p. 1813\).`

### **Important**

`process_per_host` must be less than the number of GPUs per instance and typically will be equal to the number of GPUs per instance.

For example, if you use one instance with 4-way model parallelism and 2-way data parallelism, then `processes_per_host` should be  $2 \times 4 = 8$ . Therefore, you must choose an instance that has at least 8 GPUs, such as an `ml.p3.16xlarge`.

The following image illustrates how 2-way data parallelism and 4-way model parallelism is distributed across 8 GPUs: the models is partitioned across 4 GPUs, and each partition is added to 2 GPUs.

- "custom\_mpi\_options": Use this key to pass any custom MPI options you might need. To avoid Docker warnings from contaminating your training logs, we recommend the following flag.

```
--mca btl_vader_single_copy_mechanism none
```

If you launch a training job using an `ml.p4d` instance type (such as `ml.p4d.24xlarge`), for best performance use the following flags in the `mpirun` command:

```
-x FI_EFA_USE_DEVICE_RDMA=1 -x FI_PROVIDER=efa
```

For the "smdistributed" key, a dictionary must be passed which has the only key "modelparallel". Using "modelparallel" and "dataparallel" in the same training job is not supported.

For the "modelparallel" dictionary, an inner dictionary must be passed, which enables the `modelparallel` library by setting "enabled": `True`, as well as a dict of "parameters" to customize the library. Among the parameters, the "partitions" key is required, which specifies how many model partitions are requested. To learn more about values you can use in `parameters`, see the [SageMaker distributed data parallel API documentation](#).

To launch the training job using SageMaker model parallel configured training script, you use the `Estimator.fit()` function. You can launch a SageMaker training job using a SageMaker notebook instance, or locally.

- Using a SageMaker notebook instance is recommended for new users. To see an example of how you can launch a training job using a SageMaker notebook instance, see [Distributed Training Jupyter Notebook Examples \(p. 1819\)](#).
- You can launch locally if you have [set up your Amazon credentials and Region for development](#).

Use the following resources to learn more about using the SageMaker Python SDK with these frameworks:

- [Use TensorFlow with the SageMaker Python SDK](#)
- [Use PyTorch with the SageMaker Python SDK](#)

## Extend or Adapt A Docker Container that Contains SageMaker's Distributed Model Parallel Library

To extend a pre-built container, or adapt your own container to use SageMaker's distributed model parallel library, you must use one of the PyTorch or TensorFlow GPU general framework base-images. The distributed model parallel library is included in all CUDA 11 (`cu11x`) TensorFlow 2.3.x and PyTorch 1.6.x versioned images and later. See [Available Deep Learning Containers Images](#) for a list of available images.

### Tip

It is recommended that you use the image that contains the latest version of TensorFlow or PyTorch to access the most up to date version of the SageMaker distributed model parallel library.

For example, if you are using PyTorch 1.8.1, your Dockerfile should contain a `FROM` statement similar to the following:

```
# SageMaker PyTorch image
FROM 763104351884.dkr.ecr.us-east-1.amazonaws.com/pytorch-training:1.8.1-gpu-py36-cu111-
ubuntu18.04

# Add your dependencies here
RUN ...

ENV PATH="/opt/ml/code:${PATH}"

# this environment variable is used by the SageMaker PyTorch container to determine our
# user code directory.
ENV SAGEMAKER_SUBMIT_DIRECTORY /opt/ml/code

# /opt/ml and all subdirectories are utilized by SageMaker, use the /code subdirectory to
# store your user code.
COPY cifar10.py /opt/ml/code/cifar10.py
```

Additionally, when you define a PyTorch or TensorFlow estimator, you must specify that the `entry_point` for your training script. This should be the same path identified with `ENV SAGEMAKER_SUBMIT_DIRECTORY` in your Dockerfile.

You must push this docker container to Amazon Elastic Container Registry (Amazon ECR) and use the image URI (`image_uri`) to define an estimator. See [Extend a Prebuilt Container](#) for more information.

For example, if your Dockerfile was defined using the preceding code block and used `name` and `tag` to push it to Amazon ECR, you would define a PyTorch estimator as follows. This example assumes you have already defined `smp_options` and `mpi_options`.

```
smd_mp_estimator = PyTorch(
    entry_point='/opt/ml/code/pt_mnist.py', # Identify
    source_dir='utils',
    role=role,
    instance_type='ml.p3.16xlarge',
    sagemaker_session=sagemaker_session,
    image_uri='aws_account_id.dkr.ecr.region.amazonaws.com/name:tag'
    instance_count=1,
    distribution={
        "smdistributed": smp_options,
        "mpi": mpi_options
    },
    base_job_name="SMD-MP-demo",
)
smd_mp_estimator.fit('s3://my_bucket/my_training_data/')
```

## Modify Your Training Script Using SageMaker's Distributed Model Parallel Library

Use this section to learn how to customize your training script with Amazon SageMaker's distributed model parallel library-specific API functions and parameters. We recommend you use this documentation alongside the [model parallel library API documentation](#).

The training script examples provided in these sections are simplified and designed to highlight the required changes you must make to use the library. For end to end, runnable notebook examples that demonstrate how to use a TensorFlow or PyTorch training script with the SageMaker distributed model parallel library, see [Distributed Training Jupyter Notebook Examples \(p. 1819\)](#).

## Topics

- [Modify a TensorFlow Training Script \(p. 1805\)](#)
- [Modify a PyTorch Training Script \(p. 1810\)](#)

## Modify a TensorFlow Training Script

The following are examples of training scripts that you can use to configure the SageMaker distributed model parallel library with TensorFlow versions 2.3.1 and 2.4.1 with auto-partitioning and manual partitioning. This selection of examples also includes an example integrated with Horovod for hybrid model and data parallelism. We recommend that you review [Unsupported Framework Features \(p. 1805\)](#) before creating a training script.

The required modifications you must make to your training script to use the library are listed in [TensorFlow \(p. 1805\)](#).

To learn how to modify your training script to use hybrid model and data parallelism with Horovod, see [TensorFlow with Horovod \(p. 1807\)](#).

If you want to use manual partitioning, also review [Manual partitioning with TensorFlow \(p. 1809\)](#).

### Tip

For end to end, runnable notebook examples that demonstrate how to use a TensorFlow training script with the SageMaker distributed model parallel library, see [TensorFlow Examples \(p. 1820\)](#).

Note that auto-partitioning is enabled by default. Unless otherwise specified, the following example scripts use auto-partitioning.

## Topics

- [Unsupported Framework Features \(p. 1805\)](#)
- [TensorFlow \(p. 1805\)](#)
- [TensorFlow with Horovod \(p. 1807\)](#)
- [Manual partitioning with TensorFlow \(p. 1809\)](#)

## Unsupported Framework Features

The following TensorFlow features are unsupported by the library:

- `tf.GradientTape()` is currently not supported. You can use `Optimizer.get_gradients()` or `Optimizer.compute_gradients()` instead to compute gradients.
- The `tf.train.Checkpoint.restore()` API is currently not supported. For checkpointing, use `smp.CheckpointManager` instead, which provides the same API and functionality. Note that checkpoint restores with `smp.CheckpointManager` should take place after the first step.

## TensorFlow

The following training script changes are required to run a TensorFlow model with SageMaker's distributed model parallel library:

1. Import and initialize the library with `smp.init()`.
2. Define Keras model by inheriting from `smp.DistributedModel` instead of Keras Model class. Return the model outputs from the call method of the `smp.DistributedModel` object. Be mindful that any tensors returned from the call method will be broadcast across model-parallel devices, incurring communication overhead, so any tensors that are not needed outside the call method (such as intermediate activations) should not be returned.

3. Set `drop_remainder=True` in `tf.Dataset.batch()` method. This is to ensure that the batch size is always divisible by the number of microbatches.
4. Seed the random operations in the data pipeline using `smp.dp_rank()`, e.g., `shuffle(ds, seed=smp.dp_rank())` to ensure consistency of data samples across GPUs that hold different model partitions.
5. Put the forward and backward logic in a step function and decorate it with `smp.step`.
6. Perform post-processing on the outputs across microbatches using `StepOutput` methods such as `reduce_mean`. The `smp.step` function must have a return value that depends on the output of `smp.DistributedModel`.
7. If there is an evaluation step, similarly place the forward logic inside an `smp.step`-decorated function and post-process the outputs using `StepOutput API`.

To learn more about the SageMaker's distributed model parallel library API, refer to the [API documentation](#).

```

import tensorflow as tf

# smdistributed: Import TF2.x API
import smdistributed.modelparallel.tensorflow as smp

# smdistributed: Initialize
smp.init()

# Download and load MNIST dataset.
(x_train, y_train), (x_test, y_test) = tf.keras.datasets.mnist.load_data(
    "MNIST-data-%d" % smp.rank()
)
x_train, x_test = x_train / 255.0, x_test / 255.0

# Add a channels dimension
x_train = x_train[..., tf.newaxis]
x_test = x_test[..., tf.newaxis]

# smdistributed: If needed, seed the shuffle with smp.dp_rank(), and drop_remainder # in batching to make sure batch size is always divisible by number of microbatches
train_ds = (
    tf.data.Dataset.from_tensor_slices((x_train, y_train))
    .shuffle(10000, seed=smp.dp_rank())
    .batch(256, drop_remainder=True)
)

# smdistributed: Define smp.DistributedModel the same way as Keras sub-classing API
class MyModel(smp.DistributedModel):
    def __init__(self):
        super(MyModel, self).__init__()
        # defin layers

    def call(self, x, training=None):
        # define forward pass and return the model output

model = MyModel()

loss_object = tf.keras.losses.SparseCategoricalCrossentropy(from_logits=True)
optimizer = tf.keras.optimizers.Adam()
train_accuracy = tf.keras.metrics.SparseCategoricalAccuracy(name="train_accuracy")

# smdistributed: Define smp.step. Return any tensors needed outside
@smpp.step
def get_grads(images, labels):
    predictions = model(images, training=True)
    loss = loss_object(labels, predictions)

```

```

grads = optimizer.get_gradients(loss, model.trainable_variables)
return grads, loss, predictions

@tf.function
def train_step(images, labels):
    gradients, loss, predictions = get_grads(images, labels)

    # smdistributed: Accumulate the gradients across microbatches
    gradients = [g.accumulate() for g in gradients]
    optimizer.apply_gradients(zip(gradients, model.trainable_variables))

    # smdistributed: Merge predictions and average losses across microbatches
    train_accuracy(labels, predictions.merge())
    return loss.reduce_mean()

for epoch in range(5):
    # Reset the metrics at the start of the next epoch
    train_accuracy.reset_states()
    for images, labels in train_ds:
        loss = train_step(images, labels)
        accuracy = train_accuracy.result()

```

## TensorFlow with Horovod

The SageMaker distributed model parallel library can be used with Horovod for hybrid model and data parallelism. In this case, the total number of GPUs must be divisible by the number of partitions. The quotient is inferred to be the number of model replicas or data parallelism degree. For instance, if a training job is launched with 8 processes (which corresponds to 8 GPUs), and `partitions` is 2, then the library applies 2-way model parallelism and 4-way data parallelism over the 8 GPUs.

To access the data parallel rank and model parallel rank of a process, you can use `smp.dp_rank()` and `smp.mp_rank()`, respectively. To see all MPI primitives the library exposes, see [MPI Basics](#) in the API documentation.

If you are using Horovod, you should not directly call `hvd.init`. Instead, set "horovod" to `True` in the SageMaker Python SDK `modelparallel` parameters, and the library internally initializes Horovod. This is because Horovod must be initialized based on the device assignments of model partitions, and calling `hvd.init()` directly results in problems.

Furthermore, using `hvd.DistributedOptimizer` directly results in poor performance or hangs, since this implicitly places the AllReduce operation inside `smp.step`. The recommended way to use the model parallel library with Horovod is by directly calling `hvd.allreduce` after calling `accumulate()` or `reduce_mean()` on the gradients returned from `smp.step`, as seen in the following example.

The four main changes needed in the script are:

- Adding `hvd.allreduce`
- Broadcasting variables after the first batch, as required by Horovod
- Setting the "horovod" parameter to `True` in the `modelparallel` dict in the Python SDK
- Seeding shuffling and/or sharding operations in the data pipeline with `smp.dp_rank()`.

To learn more about the SageMaker's distributed model parallel library API, refer to the [API documentation](#).

```

import tensorflow as tf
import horovod.tensorflow as hvd

```

```

# smdistributed: Import TF2.x API
import smdistributed.modelparallel.tensorflow as smp

# smdistributed: Initialize
smp.init()

# Download and load MNIST dataset.
(x_train, y_train), (x_test, y_test) = tf.keras.datasets.mnist.load_data(
    "MNIST-data-%d" % smp.rank()
)
x_train, x_test = x_train / 255.0, x_test / 255.0

# Add a channels dimension
x_train = x_train[..., tf.newaxis]
x_test = x_test[..., tf.newaxis]

# smdistributed: Seed the shuffle with smp.dp_rank(), and drop_remainder
# in batching to make sure batch size is always divisible by number of microbatches
train_ds = (
    tf.data.Dataset.from_tensor_slices((x_train, y_train))
    .shuffle(10000, seed=smp.dp_rank())
    .batch(256, drop_remainder=True)
)

# smdistributed: Define smp.DistributedModel the same way as Keras sub-classing API
class MyModel(smp.DistributedModel):
    def __init__(self):
        super(MyModel, self).__init__()
        # define layers

    def call(self, x, training=None):
        # define forward pass and return model outputs

model = MyModel()

loss_object = tf.keras.losses.SparseCategoricalCrossentropy(from_logits=True)
optimizer = tf.keras.optimizers.Adam()
train_accuracy = tf.keras.metrics.SparseCategoricalAccuracy(name="train_accuracy")

# smdistributed: Define smp.step. Return any tensors needed outside
@smpp.step
def get_grads(images, labels):
    predictions = model(images, training=True)
    loss = loss_object(labels, predictions)

    grads = optimizer.get_gradients(loss, model.trainable_variables)
    return grads, loss, predictions

@tf.function
def train_step(images, labels, first_batch):
    gradients, loss, predictions = get_grads(images, labels)

    # smdistributed: Accumulate the gradients across microbatches
    # Horovod: Allreduce the accumulated gradients
    gradients = [hvd.allreduce(g.accumulate()) for g in gradients]
    optimizer.apply_gradients(zip(gradients, model.trainable_variables))

    # Horovod: Broadcast the variables after first batch
    if first_batch:
        hvd.broadcast_variables(model.variables, root_rank=0)
        hvd.broadcast_variables(optimizer.variables(), root_rank=0)

    # smdistributed: Merge predictions across microbatches

```

```

    train_accuracy(labels, predictions.merge())
    return loss.reduce_mean()

for epoch in range(5):
    # Reset the metrics at the start of the next epoch
    train_accuracy.reset_states()

    for batch, (images, labels) in enumerate(train_ds):
        loss = train_step(images, labels, tf.constant(batch == 0))

```

## Manual partitioning with TensorFlow

Use `smp.partition` context managers to place operations in specific partition. Any operation not placed in any `smp.partition` contexts is placed in the `default_partition`. To learn more about the SageMaker's distributed model parallel library API, refer to the [API documentation](#).

```

import tensorflow as tf

# smdistributed: Import TF2.x API.
import smdistributed.modelparallel.tensorflow as smp

# smdistributed: Initialize
smp.init()

# Download and load MNIST dataset.
(x_train, y_train), (x_test, y_test) = tf.keras.datasets.mnist.load_data(
    "MNIST-data-%d" % smp.rank()
)
x_train, x_test = x_train / 255.0, x_test / 255.0

# Add a channels dimension
x_train = x_train[..., tf.newaxis]
x_test = x_test[..., tf.newaxis]

# smdistributed: If needed, seed the shuffle with smp.dp_rank(), and drop_remainder
# in batching to make sure batch size is always divisible by number of microbatches.
train_ds = (
    tf.data.Dataset.from_tensor_slices((x_train, y_train))
    .shuffle(10000, seed=smp.dp_rank())
    .batch(256, drop_remainder=True)
)

# smdistributed: Define smp.DistributedModel the same way as Keras sub-classing API.
class MyModel(smp.DistributedModel):
    def __init__(self):
        # define layers

    def call(self, x):
        with smp.partition(0):
            x = self.layer0(x)
        with smp.partition(1):

## Modify a PyTorch Training Script

The following are examples of training scripts that you can use to configure SageMaker's model parallel library with PyTorch versions 1.7.1 and 1.6.0, with auto-partitioning and manual partitioning. We recommend that you review the [Important Considerations \(p. 1810\)](#) and [Unsupported Framework Features \(p. 1812\)](#) before creating a training script.

The required modifications you must make to your training script to use the library are listed in [PyTorch \(p. 1813\)](#).

If you want to use manual partitioning, also review [Manual Partitioning with PyTorch \(p. 1814\)](#).

### Tip

For end to end, runnable notebook examples that demonstrate how to use a TensorFlow training script with the SageMaker distributed model parallel library, see [PyTorch Examples \(p. 1819\)](#).

Note that auto-partitioning is enabled by default. Unless otherwise specified, the following scripts use auto-partitioning.

### Topics

- [Important Considerations \(p. 1810\)](#)
- [Unsupported Framework Features \(p. 1812\)](#)
- [PyTorch \(p. 1813\)](#)
- [Manual Partitioning with PyTorch \(p. 1814\)](#)

### Important Considerations

When you configure a PyTorch training script using SageMaker's distributed model parallel library, you should be aware of the following:

- If you are using an optimization technique that relies on global gradient norms, for example gradient norm from the entire model, such as some variants of LAMB optimizer or global gradient clipping,

you need to gather all the norms across the model partitions for correctness. You can use the library's communication basic data types to do this.

- All `torch.Tensor` arguments to the forward methods of the `nn.Modules` in your model must be used in the computation of the module output. In other words, the library does not support the case where there is a `torch.Tensor` argument to a module on which the module output does not depend.
- The argument to the `smp.DistributedModel.backward()` call must depend on all model outputs. In other words, there cannot be an output from the `smp.DistributedModel.forward` call that is not used in the computation of the tensor that is fed into the `smp.DistributedModel.backward` call.
- If there are `torch.cuda.synchronize()` calls in your code, you might need to call `torch.cuda.set_device(smp.local_rank())` immediately before the `synchronize` call. Otherwise unnecessary CUDA contexts might be created in device 0, which will needlessly consume memory.
- Since the library places `nn.Modules` on different devices, the modules in the model must not depend on any global state that is modified inside `smp.step`. Any state that remains fixed throughout training, or that is modified outside `smp.step` in a way that is visible to all processes, is allowed.
- You don't need to move the model to GPU (for example, using `model.to(device)`) when using the library. If you try to move the model to GPU before the model is partitioned (before the first `smp.step` call), the move call is ignored. The library automatically moves the part of the model assigned to a rank to its GPU. Once training with the library starts, don't move the model to CPU and use it, as it won't have correct parameters for modules not assigned to the partition held by the process. If you want to retrain a model or use it for inference without the library after it was trained using the model parallel library, the recommended way is to save the full model using our checkpointing API and load it back to a regular PyTorch Module.
- If you have a list of modules such that output of one feeds into another, replacing that list with `nn.Sequential` can significantly improve performance.
- The weight update (`optimizer.step()`) needs to happen outside of `smp.step` because that is when the entire backward pass is done and gradients are ready. When using a hybrid model with model and data parallelism, at this point, Allreduce of gradients is also guaranteed to finish.
- When using the library in combination with data parallelism, make sure that the number of batches on all data parallel ranks is the same so that Allreduce does not hang waiting for a rank which is not participating in the step.
- If you launch a training job using an `ml.p4d` instance type (such as `ml.p4d.24xlarge`), you must set the data loader variable `num_workers=0`. For example, you may define your `DataLoader` as follows:

```
dataloader = torch.utils.data.DataLoader(
    data,
    batch_size=batch_size,
    num_workers=0,
    pin_memory=True,
    drop_last=True,
    shuffle=shuffle,
)
```

- The inputs to `smp.step` must be the model inputs generated by `DataLoader`. This is because `smp.step` internally splits the input tensors along the batch dimension and pipelines them. This means that passing `DataLoader` itself to the `smp.step` function to generate the model inputs inside does not work.

For example, if you define a `DataLoader` as follows:

```
train_loader = torch.utils.data.DataLoader(dataset, batch_size=64, drop_last=True)
```

You should access the model inputs generated by `train_loader` and pass those to an `smp.step` decorated function. Do not pass `train_loader` directly to the `smp.step` function.

```

def train(model, device, train_loader, optimizer):
    model.train()
    for batch_idx, (data, target) in enumerate(train_loader):
        ...
        _, loss_mb = train_step(model, data, target)
        ...

@smp.step
def train_step(model, data, target):
    ...
    return output, loss

```

- The input tensors to `smp.step` must be moved to the current device using `.to()` API, which must take place after the `torch.cuda.set_device(local_rank())` call.

For example, you may define the `train` function as follows. This function adds `data` and `target` to the current device using `.to()` API before using those input tensors to call `train_step`.

```

def train(model, device, train_loader, optimizer):
    model.train()
    for batch_idx, (data, target) in enumerate(train_loader):
        # smdistributed: Move input tensors to the GPU ID used by the current process,
        # based on the set_device call.
        data, target = data.to(device), target.to(device)
        optimizer.zero_grad()
        # Return value, loss_mb is a StepOutput object
        _, loss_mb = train_step(model, data, target)

        # smdistributed: Average the loss across microbatches.
        loss = loss_mb.reduce_mean()

    optimizer.step()

```

The input tensors to this `smp.set` decorated function have been moved to the current device in the `train` function above. The model does *not* need to be moved to the current device. The library automatically moves the part of the model assigned to a rank to its GPU.

```

@smp.step
def train_step(model, data, target):
    output = model(data)
    loss = F.nll_loss(output, target, reduction="mean")
    model.backward(loss)
    return output, loss

```

## Unsupported Framework Features

The following PyTorch features are unsupported by SageMaker's distributed model parallel library:

- When using data parallelism with DDP, the `DistributedDataParallel` wrapper is not supported. The library internally manages integrating with DDP, including parameter broadcast and gradient Allreduce. When using the library, module buffers are only broadcast once at the start of training. If your model has module buffers and you require module buffers to be synchronized across data parallel groups at each step, you can do so through the `torch.distributed` API, using the process group that can be obtained via `smp.get_dp_process_group()`.
- For mixed precision training, the `apex.amp` module is not supported. The recommended way to use the library with automatic mixed-precision is to use `torch.cuda.amp`, with the exception of using `smp.amp.GradScaler` instead of the implementation in torch.
- `torch.jit.ScriptModules` or `ScriptFunctions` are not supported by `smp.DistributedModel`.

- apex : FusedLayerNorm, FusedAdam, FusedLAMB, and FusedNovoGrad from apex are not supported. You can use the library implementations of these through smp.optimizers and smp.nn APIs instead.

## PyTorch

The following training script changes are required to run a PyTorch model with SageMaker's distributed model parallel library:

1. Import and initialize the library with `smp.init()`.
2. Wrap the model with `smp.DistributedModel`. Be mindful that any tensors returned from the forward method of the underlying `nn.Module` object will be broadcast across model-parallel devices, incurring communication overhead, so any tensors that are not needed outside the call method (such as intermediate activations) should not be returned.
3. Wrap the optimizer with `smp.DistributedOptimizer`.
4. Use the returned `DistributedModel` object instead of a user model.
5. Put the forward and backward logic in a step function and decorate it with `smp.step`.
6. Restrict each process to its own device through `torch.cuda.set_device(smp.local_rank())`.
7. Move the input tensors to the GPU using the `.to()` API before the `smp.step` call (see example below).
8. Replace `torch.Tensor.backward` and `torch.autograd.backward` with `DistributedModel.backward`.
9. Perform post-processing on the outputs across microbatches using `StepOutput` methods such as `reduce_mean`.
- 10 If there is an evaluation step, similarly place the forward logic inside an `smp.step`-decorated function and post-process the outputs using `StepOutput API`.
- 11 Set `drop_last=True` in `DataLoader`. Alternatively, manually skip a batch in the training loop if the batch size is not divisible by the number of microbatches.

To learn more about the SageMaker's distributed model parallel library API, refer to the [API documentation](#).

```

import torch
import torch.nn as nn
import torch.nn.functional as F
import torch.optim as optim

    def __init__(self):
        super(GroupedNet, self).__init__()
        # define layers

    def forward(self, x):
        # define forward pass and return model outputs

# smdistributed: Define smp.step. Return any tensors needed outside.
@smp.step
def train_step(model, data, target):
    output = model(data)
    loss = F.nll_loss(output, target, reduction="mean")
    model.backward(loss)

```

```

        return output, loss

def train(model, device, train_loader, optimizer):
    model.train()
    for batch_idx, (data, target) in enumerate(train_loader):
        # smdistributed: Move input tensors to the GPU ID used by the current process,
        # based on the set_device call.
        data, target = data.to(device), target.to(device)
        optimizer.zero_grad()
        # Return value, loss_mb is a StepOutput object
        _, loss_mb = train_step(model, data, target)

        # smdistributed: Average the loss across microbatches.
        loss = loss_mb.reduce_mean()

        optimizer.step()

# smdistributed: initialize the backend
smp.init()

# smdistributed: Set the device to the GPU ID used by the current process.
# Input tensors should be transferred to this device.
torch.cuda.set_device(smp.local_rank())
device = torch.device("cuda")

# smdistributed: Download only on a single process per instance.
# When this is not present, the file is corrupted by multiple processes trying
# to download and extract at the same time
dataset = datasets.MNIST("../data", train=True, download=False)

# smdistributed: Shard the dataset based on data-parallel ranks
if smp.dp_size() > 1:
    partitions_dict = {f"{i}": 1 / smp.dp_size() for i in range(smp.dp_size())}
    dataset = SplitDataset(dataset, partitions=partitions_dict)
    dataset.select(f"{{smp.dp_rank()}}")

# smdistributed: Set drop_last=True to ensure that batch size is always divisible
# by the number of microbatches
train_loader = torch.utils.data.DataLoader(dataset, batch_size=64, drop_last=True)

model = GroupedNet()
optimizer = optim.Adadelta(model.parameters(), lr=4.0)

# smdistributed: Use the DistributedModel container to provide the model
# to be partitioned across different ranks. For the rest of the script,
# the returned DistributedModel object should be used in place of
# the model provided for DistributedModel class instantiation.
model = smp.DistributedModel(model)
optimizer = smp.DistributedOptimizer(optimizer)

train(model, device, train_loader, optimizer)

```

## Manual Partitioning with PyTorch

Use `smp.partition` context managers to place modules in specific devices. Any module not placed in any `smp.partition` contexts is placed in the `default_partition`. The `default_partition` needs to be provided if `auto_partition` is set to `False`. The modules that are created within a specific `smp.partition` context are placed on the corresponding partition.

To learn more about the SageMaker's distributed model parallel library API, refer to the [API documentation](#).

```
import torch
```

```

import torch.nn as nn
import torch.nn.functional as F
import torch.optim as optim
from torchnet.dataset import SplitDataset

train(model, device, train_loader, optimizer)
```

## SageMaker distributed model parallel Configuration Tips and Pitfalls

Review the following tips and pitfalls before using Amazon SageMaker's distributed model parallel library. This list includes tips that are applicable across frameworks. For TensorFlow and PyTorch specific tips, see [Modify a TensorFlow Training Script \(p. 1805\)](#) and [Modify a PyTorch Training Script \(p. 1810\)](#), respectively.

### Batch Size and Number of Microbatches

- The library is most efficient when the batch size is increased. For use cases where the model fits within a single device, but can only be trained with a small batch size, batch size can and should be increased after the library is integrated. Model parallelism saves memory for large models, enabling you to train using batch sizes that previously did not fit in memory.
- Choosing a number of microbatches that is too small or too large can hurt performance. The library executes each microbatch sequentially in each device, so microbatch size (batch size divided by number of microbatches) must be large enough to fully utilize each GPU. At the same time, pipeline efficiency increases with the number of microbatches, so striking the right balance is important. Typically, a good starting point is to try 2 or 4 microbatches, increasing the batch size to the memory limit, and then experiment with larger batch sizes and numbers of microbatches. As the number of microbatches is increased, larger batch sizes might become feasible if an interleaved pipeline is used.
- Your batch size must be always divisible by the number of microbatches. Note that depending on the size of the dataset, sometimes the last batch of every epoch can be of a smaller size than the rest, and this smaller batch needs to be divisible by the number of microbatches as well. If it is not, you can set `drop_remainder=True` in the `tf.Dataset.batch()` call (in TensorFlow), or set `drop_last=True` in `DataLoader` (in PyTorch), so that this last, small batch is not used. If you are using a different API for the data pipeline, you might need to manually skip the last batch whenever it is not divisible by the number of microbatches.

### Manual Partitioning

- If you use manual partitioning, be mindful of the parameters that are consumed by multiple operations and modules in your model, such as the embedding table in transformer architectures. Modules that share the same parameter must be placed in the same device for correctness. When auto-partitioning is used, the library automatically enforces this constraint.

### Data Preparation

- If the model takes multiple inputs, make sure you seed the random operations in your data pipeline (e.g., shuffling) with `smp.dp_rank()`. If the dataset is being deterministically sharded across data parallel devices, make sure that the shard is indexed by `smp.dp_rank()`. This is to make sure that the order of the data seen on all ranks that form a model partition is consistent.

### Returning Tensors from `smp.DistributedModel`

- Any tensor that is returned from the `smp.DistributedModel.call` (for TensorFlow) or `smp.DistributedModel.forward` (for PyTorch) function is broadcast to all other ranks, from the rank that computed that particular tensor. As a result, any tensor that is not needed outside the call and forward methods (intermediate activations, for example) should not be returned, as this causes needless communication and memory overhead and hurts performance.

### The `@smp.step` Decorator

- If an `smp.step`-decorated function has a tensor argument that does not have a batch dimension, the argument name must be provided in the `non_split_inputs` list when calling `smp.step`. This prevents the library from attempting to split the tensor into microbatches. For more information see `smp.step` in the API documentation.

## Model Parallel Troubleshooting

If you run into an error, you can use the following list to try to troubleshoot your training job. If the problem persists, contact Amazon Support.

### Topics

- [Considerations for Using SageMaker Debugger with SageMaker Distributed Model Parallel \(p. 1817\)](#)
- [Saving Checkpoints \(p. 1818\)](#)
- [Convergence Using Model Parallel and TensorFlow \(p. 1819\)](#)

## Considerations for Using SageMaker Debugger with SageMaker Distributed Model Parallel

SageMaker Debugger is not available for SageMaker distributed model parallel. Debugger is enabled by default for all SageMaker TensorFlow and PyTorch training jobs, and you might see an error that looks like the following:

```
FileNotFoundException: [Errno 2] No such file or directory: '/opt/ml/checkpoints/metadata.json.sagemaker-uploading'
```

To fix this issue, disable Debugger by passing `debugger_hook_config=False` when creating a framework estimator as shown in the following example.

```
bucket=sagemaker.Session().default_bucket()
base_job_name="sagemaker-checkpoint-test"
checkpoint_in_bucket="checkpoints"

# The S3 URI to store the checkpoints
checkpoint_s3_bucket="s3://{}//{}//{}".format(bucket, base_job_name, checkpoint_in_bucket)

estimator = TensorFlow(
    ...
    distribution={"smdistributed": {"modelparallel": { "enabled": True }}},
    checkpoint_s3_uri=checkpoint_s3_bucket,
    checkpoint_local_path="/opt/ml/checkpoints",
    debugger_hook_config=False
)
```

## Saving Checkpoints

You might run into the following error when saving checkpoints of a large model on SageMaker:

```
InternalServerError: We encountered an internal error. Please try again
```

This could be caused by a SageMaker limitation while uploading the local checkpoint to Amazon S3 during training. To disable checkpointing in SageMaker, use the following example to explicitly upload the checkpoints.

If you run into the preceding error, do not use `checkpoint_s3_uri` with the SageMaker estimator call. While saving checkpoints for larger models, we recommend saving checkpoints to a custom directory and passing the same to the helper function (as a `local_path` argument).

```
import os

def aws_s3_sync(source, destination):
    """aws s3 sync in quiet mode and time profile"""
    import time, subprocess
    cmd = ["aws", "s3", "sync", "--quiet", source, destination]
    print(f"Syncing files from {source} to {destination}")
    start_time = time.time()
    p = subprocess.Popen(cmd, stdout=subprocess.PIPE, stderr=subprocess.PIPE)
    p.wait()
    end_time = time.time()
    print("Time Taken to Sync: ", (end_time-start_time))
    return

def sync_local_checkpoints_to_s3(local_path="/opt/ml/checkpoints",
                                 s3_uri=os.path.dirname(os.path.dirname(os.getenv('SM_MODULE_DIR', '')))+'/checkpoints'):
    """ sample function to sync checkpoints from local path to s3 """

    import boto3
    #check if local path exists
    if not os.path.exists(local_path):
        raise RuntimeError("Provided local path {local_path} does not exist. Please check")

    #check if s3 bucket exists
    s3 = boto3.resource('s3')
    if not s3_uri.startswith("s3://"):
        raise ValueError(f"Provided s3 uri {s3_uri} is not valid.")

    s3_bucket = s3_uri.replace('s3://','').split('/')[0]
    print(f"S3 Bucket: {s3_bucket}")
    try:
        s3.meta.client.head_bucket(Bucket=s3_bucket)
    except Exception as e:
        raise e
    aws_s3_sync(local_path, s3_uri)
    return

def sync_s3_checkpoints_to_local(local_path="/opt/ml/checkpoints",
                                 s3_uri=os.path.dirname(os.path.dirname(os.getenv('SM_MODULE_DIR', '')))+'/checkpoints'):
    """ sample function to sync checkpoints from s3 to local path """

    import boto3
    #try to create local path if it does not exist
    if not os.path.exists(local_path):
        print(f"Provided local path {local_path} does not exist. Creating...")
        try:
            os.makedirs(local_path)
        except Exception as e:
            raise RuntimeError(f"Failed to create {local_path}")
```

```
#check if s3 bucket exists
s3 = boto3.resource('s3')
if not s3_uri.startswith("s3://"):
    raise ValueError(f"Provided s3 uri {s3_uri} is not valid.")

s3_bucket = s3_uri.replace('s3://','').split('/')[0]
print(f"S3 Bucket: {s3_bucket}")
try:
    s3.meta.client.head_bucket(Bucket=s3_bucket)
except Exception as e:
    raise e
aws_s3_sync(s3_uri, local_path)
return
```

Usage of helper functions:

```
#base_s3_uri - user input s3 uri or save to model directory (default)
#curr_host - to save checkpoints of current host
#iteration - current step/epoch during which checkpoint is saved

# save checkpoints on every node using local_rank
if smp.local_rank() == 0:
    base_s3_uri = os.path.dirname(os.path.dirname(os.getenv('SM_MODULE_DIR', '')))
    curr_host = os.environ['SM_CURRENT_HOST']
    full_s3_uri = f'{base_s3_uri}/checkpoints/{curr_host}/{iteration}'
    sync_local_checkpoints_to_s3(local_path=checkpoint_dir, s3_uri=full_s3_uri)
```

## Convergence Using Model Parallel and TensorFlow

When you use SageMaker multi-node training with TensorFlow and distributed model parallel, the loss may not converge as expected because the order of training input files may be different on each node. This may cause different ranks in the same model parallel group to work on different input files, causing inconsistencies. To prevent this, ensure the input files are ordered the same way in all the ranks before they get converted to TensorFlow datasets. One way to achieve this is to sort the input file names in the training script.

## Distributed Training Jupyter Notebook Examples

The following notebooks provide example Amazon SageMaker distributed implementations for popular deep learning frameworks and models. For vision (image) models, try MNIST or MaskRCNN. For language (text) models, try BERT.

These notebooks are provided in the [SageMaker examples repository](#). You can also browse them on the [SageMaker examples website](#).

The examples are set up to use p3.16xlarge instances for the worker nodes, but you may choose other p3 instance types if you wish. You can test a notebook using a cluster with only 1 node, but to see any performance benefit, you should use a cluster of multiple nodes (2 or more). The examples call out the section in which you modify this configuration.

## PyTorch Examples

### SageMaker Distributed Data Parallel

- MNIST with PyTorch 1.6 and SageMaker Data Parallel
- MaskRCNN with PyTorch 1.6 and SageMaker Data Parallel
- BERT with PyTorch 1.6 and SageMaker Data Parallel

### SageMaker Distributed Model Parallel

- MNIST with PyTorch 1.6 and SageMaker Model Parallel
- BERT with PyTorch 1.6 and SageMaker Model Parallel

## TensorFlow Examples

### SageMaker Distributed Data Parallel

- MNIST with TensorFlow 2.3.1 and SageMaker Data Parallel
- MaskRCNN with TensorFlow 2.3.1 and SageMaker Data Parallel
- BERT with TensorFlow 2.3.1 and SageMaker Data Parallel

### SageMaker Distributed Model Parallel

- MNIST with TensorFlow 2.3.1 and SageMaker Model Parallel

## Use a SageMaker Notebook Instance

To use the provided examples, we recommend that you use an Amazon SageMaker notebook instance. A notebook instance is a machine learning (ML)-optimized Amazon EC2 instance running the Jupyter Notebook and JupyterServer apps. If you do not have an active notebook instance, follow the instructions in [Create a Notebook Instance \(p. 120\)](#) in the SageMaker developer guide to create one.

After you have created an instance, in the **Notebook instances** area of the SageMaker console, do the following:

1. Open **JupyterLab**.
2. Select the examples icon (  ) in the left tray.
3. Browse the examples for **Training** and look for notebooks titled *Distributed Data Parallel* or *Distributed Model Parallel*.

## Use SageMaker Studio

You can run these example Jupyter Notebooks in SageMaker Studio. To download and use an example notebook, do the following in Studio:

1. Open a terminal.
2. In the command line, navigate to the SageMaker folder.

```
$ cd SageMaker
```

3. Clone the SageMaker examples repo.

```
git clone https://github.com/aws/amazon-sagemaker-examples.git
```

4. In the JupyterLab interface, navigate into the `amazon-sagemaker-examples` folder.
5. In the `training/distributed_training` folder, there are folders for frameworks, and in each of these, there are folders for `data_parallel` and `model_parallel`. Choose the example of your choice and follow the instructions to launch distributed training with an SageMaker distributed training library.

# Detect Posttraining Data and Model Bias

Posttraining bias analysis can help reveal biases that might have emanated from biases in the data, or from biases introduced by the classification and prediction algorithms. These analyses take into consideration the data, including the labels, and the predictions of a model. You assess performance by analyzing predicted labels or by comparing the predictions with the observed target values in the data with respect to groups with different attributes. There are different notions of fairness, each requiring different bias metrics to measure.

There are legal concepts of fairness that might not be easy to capture because they are hard to detect. For example, the US concept of disparate impact that occurs when a group, referred to as a less favored facet  $d$ , experiences an adverse effect even when the approach taken appears to be fair. This type of bias might not be due to a machine learning model, but might still be detectable by posttraining bias analysis.

Amazon SageMaker Clarify tries to ensure a consistent use of terminology. For a list of terms and their definitions, see [Amazon SageMaker Clarify Terms for Bias and Fairness \(p. 561\)](#).

For additional information about posttraining bias metrics, see [Fairness Measures for Machine Learning in Finance](#).

## Sample Notebooks

Amazon SageMaker Clarify provides the following sample notebook for posttraining bias detection:

- [Explainability and bias detection with Amazon SageMaker Clarify](#) – Use SageMaker Clarify to create a processing job for the detecting bias and explaining model predictions with feature attributions.

This notebook has been verified to run in Amazon SageMaker Studio only. If you need instructions on how to open a notebook in Amazon SageMaker Studio, see [Create or Open an Amazon SageMaker Studio Notebook \(p. 79\)](#). If you're prompted to choose a kernel, choose **Python 3 (Data Science)**.

## Measure Posttraining Data and Model Bias

Amazon SageMaker Clarify provides eleven posttraining data and model bias metrics to help quantify various conceptions of fairness. These concepts cannot all be satisfied simultaneously and the selection depends on specifics of the cases involving potential bias being analyzed. Most of these metrics are a combination of the numbers taken from the binary classification confusion matrices for the different demographic groups. Because fairness and bias can be defined by a wide range of metrics, human judgment is required to understand and choose which metrics are relevant to the individual use case, and customers should consult with appropriate stakeholders to determine the appropriate measure of fairness for their application.

We use the following notation to discuss the bias metrics. The conceptual model described here is for binary classification, where events are labeled as having only two possible outcomes in their sample space, referred to as positive (with value 1) and negative (with value 0). This framework is usually extensible to multiclass classification in a straightforward way or to cases involving continuous valued outcomes when needed. In the binary classification case, positive and negative labels are assigned

to outcomes recorded in a raw dataset for a favored facet  $a$  and for a disfavored facet  $d$ . These labels  $y$  are referred to as *observed labels* to distinguish them from the *predicted labels*  $y'$  that are assigned by a machine learning model during the training or inferences stages of the ML lifecycle. These labels are used to define probability distributions  $P_a(y)$  and  $P_d(y)$  for their respective facet outcomes.

- **labels:**
  - $y$  represents the  $n$  observed labels for event outcomes in a training dataset.
  - $y'$  represents the predicted labels for the  $n$  observed labels in the dataset by a trained model.
- **outcomes:**
  - A positive outcome (with value 1) for a sample, such as an application acceptance.
    - $n^{(1)}$  is the number of observed labels for positive outcomes (acceptances).
    - $n'^{(1)}$  is the number of predicted labels for positive outcomes (acceptances).
  - A negative outcome (with value 0) for a sample, such as an application rejection.
    - $n^{(0)}$  is the number of observed labels for negative outcomes (rejections).
    - $n'^{(0)}$  is the number of predicted labels for negative outcomes (rejections).
- **facet values:**
  - facet  $a$  – The feature value that defines a demographic that bias favors.
    - $n_a$  is the number of observed labels for the favored facet value:  $n_a = n_a^{(1)} + n_a^{(0)}$  the sum of the positive and negative observed labels for the value facet  $a$ .
    - $n'_a$  is the number of predicted labels for the favored facet value:  $n'_a = n'_a^{(1)} + n'_a^{(0)}$  the sum of the positive and negative predicted outcome labels for the facet value  $a$ . Note that  $n'_a = n_a$ .
  - facet  $d$  – The feature value that defines a demographic that bias disfavors.
    - $n_d$  is the number of observed labels for the disfavored facet value:  $n_d = n_d^{(1)} + n_d^{(0)}$  the sum of the positive and negative observed labels for the facet value  $d$ .
    - $n'_d$  is the number of predicted labels for the disfavored facet value:  $n'_d = n'_d^{(1)} + n'_d^{(0)}$  the sum of the positive and negative predicted labels for the facet value  $d$ . Note that  $n'_d = n_d$ .
- **probability distributions for outcomes of the labeled facet data outcomes:**
  - $P_a(y)$  is the probability distribution of the observed labels for facet  $a$ . For binary labeled data, this distribution is given by the ratio of the number of samples in facet  $a$  labeled with positive outcomes to the total number,  $P_a(y^1) = n_a^{(1)} / n_a$ , and the ratio of the number of samples with negative outcomes to the total number,  $P_a(y^0) = n_a^{(0)} / n_a$ .
  - $P_d(y)$  is the probability distribution of the observed labels for facet  $d$ . For binary labeled data, this distribution is given by the number of samples in facet  $d$  labeled with positive outcomes to the total number,  $P_d(y^1) = n_d^{(1)} / n_d$ , and the ratio of the number of samples with negative outcomes to the total number,  $P_d(y^0) = n_d^{(0)} / n_d$ .

The following table contains a cheat sheet for quick guidance and links to the posttraining bias metrics.

### Posttraining Bias Metrics

posttraining bias metric	Description	Example question	Interpreting metric values
Difference in Positive Proportions in Predicted Labels (DPPL) (p. 1830)	Measures the difference in the proportion of positive predictions between the favored facet $a$ and the disfavored facet $d$ .	Has there been an imbalance across demographic groups in the predicted positive outcomes that might indicate bias?	Range for normalized binary & multiclass facet labels: $[-1, +1]$ Range for continuous labels: $(-\infty, +\infty)$ Interpretation:

posttraining bias metric	Description	Example question	Interpreting metric values
			<ul style="list-style-type: none"> <li>Positive values indicate that the favored facet <math>a</math> has a higher proportion of predicted positive outcomes.</li> <li>Values near zero indicate a more equal proportion of predicted positive outcomes between facets.</li> <li>Negative values indicate the disfavored facet <math>d</math> has a higher proportion of predicted positive outcomes.</li> </ul>
<a href="#">Disparate Impact (DI) (p. 1831)</a>	Measures the ratio of proportions of the predicted labels for the favored facet $a$ and the disfavored facet $d$ .	Has there been an imbalance across demographic groups in the predicted positive outcomes that might indicate bias?	<p>Range for normalized binary, multiclass, and continuous labels: <math>[0, \infty)</math></p> <p>Interpretation:</p> <ul style="list-style-type: none"> <li>Values greater than 1 indicate the favored facet <math>a</math> has a higher proportion of predicted positive outcomes.</li> <li>A value of 1 indicates that we have demographic parity.</li> <li>Values less than 1 indicate the disfavored facet <math>d</math> has a higher proportion of predicted positive outcomes.</li> </ul>

posttraining bias metric	Description	Example question	Interpreting metric values
<a href="#">Difference in Conditional Acceptance (DCAcc) (p. 1831)</a>	Compares the observed labels to the labels predicted by a model and assesses whether this is the same across facets for predicted positive outcomes (acceptances).	Are there more or less acceptances for loan applications than predicted for one age group as compared to another based on qualifications?	<p>The range for binary, multicategory facet, and continuous labels: <math>(-\infty, +\infty)</math>.</p> <ul style="list-style-type: none"> <li>Positive values indicate a possible bias against the qualified applicants from the disfavored facet <math>d</math>.</li> <li>Values near zero indicate that qualified applicants from both facets are being accepted in a similar way.</li> <li>Negative values indicate a possible bias against the qualified applicants from the favored facet <math>a</math>.</li> </ul>
<a href="#">Difference in Conditional Rejection (DCR) (p. 1832)</a>	Compares the observed labels to the labels predicted by a model and assesses whether this is the same across facets for negative outcomes (rejections).	Are there more or less rejections for loan applications than predicted for one age group as compared to another based on qualifications?	<p>The range for binary, multicategory facet, and continuous labels: <math>(-\infty, +\infty)</math>.</p> <ul style="list-style-type: none"> <li>Positive values indicate a possible bias against the qualified applicants from the disfavored facet <math>d</math>.</li> <li>Values near zero indicate that qualified applicants from both facets are being rejected in a similar way.</li> <li>Negative values indicate a possible bias against the qualified applicants from the favored facet <math>a</math>.</li> </ul>

posttraining bias metric	Description	Example question	Interpreting metric values
<a href="#">Recall Difference (RD) (p. 1834)</a>	Compares the recall of the model for the favored and disfavored facets.	Is there an age-based bias in lending due to a model having higher recall for one age group as compared to another?	<p>Range for binary and multiclass classification: [-1, +1].</p> <ul style="list-style-type: none"> <li>Positive values suggest that the model finds more of the true positives for facet <math>a</math> and is biased against the disfavored facet <math>d</math>.</li> <li>Values near zero suggest that the model finds about the same number of true positives in both facets and is not biased.</li> <li>Negative values suggest that the model finds more of the true positives for facet <math>d</math> and is biased against the favored facet <math>a</math>.</li> </ul>

posttraining bias metric	Description	Example question	Interpreting metric values
<a href="#">Difference in Acceptance Rates (DAR) (p. 1835)</a>	Measures the difference in the ratios of the observed positive outcomes (TP) to the predicted positives (TP + FP) between the favored and disfavored facets.	Does the model have equal precision when predicting loan acceptances for qualified applicants across all age groups?	<p>The range for binary, multicategory facet, and continuous labels is [-1, +1].</p> <ul style="list-style-type: none"> <li>Positive values indicate a possible bias against facet <math>d</math> caused by the occurrence of relatively more false positives in the disfavored facet <math>d</math>.</li> <li>Values near zero indicate the observed labels for positive outcomes (acceptances) are being predicted with equal precision for both facets by the model.</li> <li>Negative values indicate a possible bias against facet <math>a</math> caused by the occurrence of relatively more false positives in the favored facet <math>a</math>.</li> </ul>

<b>posttraining bias metric</b>	<b>Description</b>	<b>Example question</b>	<b>Interpreting metric values</b>
<a href="#">Difference in Rejection Rates (DRR) (p. 1835)</a>	Measures the difference in the ratios of the observed negative outcomes ( $TN$ ) to the predicted negatives ( $TN + FN$ ) between the disfavored and favored facets.	Does the model have equal precision when predicting loan rejections for unqualified applicants across all age groups?	<p>The range for binary, multicategory facet, and continuous labels is <math>[-1, +1]</math>.</p> <ul style="list-style-type: none"> <li>Positive values indicate a possible bias caused by the occurrence of relatively more false negatives in the favored facet <math>a</math>.</li> <li>Values near zero indicate the observed labels for negative outcomes (rejections) are being predicted with equal precision for both facets by the model.</li> <li>Negative values indicate a possible bias caused by the occurrence of relatively more false negatives in the disfavored facet <math>d</math>.</li> </ul>

posttraining bias metric	Description	Example question	Interpreting metric values
<a href="#">Accuracy Difference (AD) (p. 1836)</a>	Measures the difference between the prediction accuracy for the favored and disfavored facets.	Does the model predict labels as accurately for applications across all demographic groups?	<p>The range for binary and multicategory facet labels is <math>[-1, +1]</math>.</p> <ul style="list-style-type: none"> <li>Positive values indicate that facet <math>d</math> suffers more from some combination of false positives (Type I errors) or false negatives (Type II errors). This means there is a potential bias against the disfavored facet <math>d</math>.</li> <li>Values near zero occur when the prediction accuracy for facet <math>a</math> is similar to that for facet <math>d</math>.</li> <li>Negative values indicate that facet <math>a</math> suffers more from some combination of false positives (Type I errors) or false negatives (Type II errors). This means there is a bias against the favored facet <math>a</math>.</li> </ul>
<a href="#">Treatment Equality (TE) (p. 1837)</a>	Measures the difference in the ratio of false positives to false negatives between the favored and disfavored facets.	In loan applications, is the relative ratio of false positives to false negatives the same across all age demographics?	<p>The range for binary and multicategory facet labels: <math>(-\infty, +\infty)</math>.</p> <ul style="list-style-type: none"> <li>Positive values occur when the ratio of false positives to false negatives for facet <math>a</math> is greater than that for facet <math>d</math>.</li> <li>Values near zero occur when the ratio of false positives to false negatives for facet <math>a</math> is similar to that for facet <math>d</math>.</li> <li>Negative values occur when the ratio of false positives to false negatives for facet <math>a</math> is less than that for facet <math>d</math>.</li> </ul>

posttraining bias metric	Description	Example question	Interpreting metric values
<a href="#">Conditional Demographic Disparity in Predicted Labels (CDDPL) (p. 1838)</a>	Measures the disparity of predicted labels between the facets as a whole, but also by subgroups.	Do some demographic groups have a larger proportion of rejections for loan application outcomes than their proportion of acceptances?	<p>The range of CDDPL values for binary, multicategory, and continuous outcomes: [-1, +1]</p> <ul style="list-style-type: none"> <li>Positive values indicate an outcomes where facet <math>d</math> is rejected more than accepted.</li> <li>Near zero indicates no demographic disparity on average.</li> <li>Negative values indicate an outcomes where facet <math>a</math> is rejected more than accepted.</li> </ul>
<a href="#">Counterfactual Fliptest (FT) (p. 1839)</a>	Examines each member of facet $d$ and assesses whether similar members of facet $a$ have different model predictions.	Are a group of a specific age demographic, matched closely on all features with another age group, paid on average more than that other age group?"	<p>The range for binary and multicategory facet labels is [-1, +1].</p> <ul style="list-style-type: none"> <li>Positive values occur when the number of unfavorable counterfactual fliptest decisions for the disfavored facet <math>d</math> exceeds the favorable ones.</li> <li>Values near zero occur when the number of unfavorable and favorable counterfactual fliptest decisions balance out.</li> <li>Negative values occur when the number of unfavorable counterfactual fliptest decisions for the disfavored facet <math>d</math> is less than the favorable ones.</li> </ul>

For additional information about posttraining bias metrics, see [A Family of Fairness Measures for Machine Learning in Finance](#).

**more false negatives in the disfavored facet d.**

- Difference in Positive Proportions in Predicted Labels (DPPL) (p. 1830)

- Counterfactual Fliptest (FT) (p. 1839)

## Difference in Positive Proportions in Predicted Labels (DPPL)

The difference in positive proportions in predicted labels (DPPL) metric determines whether the model predicts outcomes differently for each facet. It is defined as the difference between the proportion of positive predictions ( $y' = 1$ ) for facet  $a$  and the proportion of positive predictions ( $y' = 1$ ) for facet  $d$ . For example, if the model predictions grant loans to 60% of a middle-aged group (facet  $a$ ) and 50% other age groups (facet  $d$ ), it might be biased against facet  $d$ . In this example, you need to determine whether the 10% difference is material to a case for bias. A comparison of DPL with DPPL assesses whether bias initially present in the dataset increases or decreases in the model predictions after training.

The formula for the difference in proportions of predicted labels:

$$DPPL = q'_a - q'_d$$

Where:

- $q'_a = n'_a^{(1)} / n_a$  is the predicted proportion of facet  $a$  who get a positive outcome of value 1. In our example, the proportion of a middle-aged facet predicted to get granted a loan. Here  $n'_a^{(1)}$  represents the number of members of facet  $a$  who get a positive predicted outcome of value 1 and  $n_a$  the is number of members of facet  $a$ .
- $q'_d = n'_d^{(1)} / n_d$  is the predicted proportion of facet  $d$  who get a positive outcome of value 1. In our example, a facet of older and younger people predicted to get granted a loan. Here  $n'_d^{(1)}$  represents the number of members of facet  $d$  who get a positive predicted outcome and  $n_d$  the is number of members of facet  $d$ .

If DPPL is close enough to 0, it means that posttraining *demographic parity* has been achieved.

For binary and multicategory facet labels, the normalized DPL values range over the interval  $[-1, 1]$ . For continuous labels, the values vary over the interval  $(-\infty, +\infty)$ .

- Positive DPPL values indicate that facet  $a$  has a higher proportion of predicted positive outcomes when compared with facet  $d$ .

This is referred to as *positive bias*.

- Values of DPPL near zero indicate a more equal proportion of predicted positive outcomes between facets  $a$  and  $d$  and a value of zero indicates perfect demographic parity.
- Negative DPPL values indicate that facet  $d$  has a higher proportion of predicted positive outcomes when compared with facet  $a$ . This is referred to as *negative bias*.

## Disparate Impact (DI)

The difference in positive proportions in the predicted labels metric can be assessed in the form of a ratio.

The comparison of positive proportions in predicted labels metric can be assessed in the form of a ratio instead of as a difference, as it is with the [Difference in Positive Proportions in Predicted Labels \(DPPL\) \(p. 1830\)](#). The disparate impact (DI) metric is defined as the ratio of the proportion of positive predictions ( $y' = 1$ ) for facet  $a$  over the proportion of positive predictions ( $y' = 1$ ) for facet  $d$ . For example, if the model predictions grant loans to 60% of a middle-aged group (facet  $a$ ) and 50% other age groups (facet  $d$ ), then  $DI = .6/.5 = 1.2$ , which indicates a positive bias and an adverse impact on facet  $d$ .

The formula for the ratio of proportions of the predicted labels:

$$DI = q'_d/q'_a$$

Where:

- $q'_a = n'_a^{(1)}/n_a$  is the predicted proportion of facet  $a$  who get a positive outcome of value 1. In our example, the proportion of a middle-aged facet predicted to get granted a loan. Here  $n'_a^{(1)}$  represents the number of members of facet  $a$  who get a positive predicted outcome and  $n_a$  the is number of members of facet  $a$ .
- $q'_d = n'_d^{(1)}/n_d$  is the predicted proportion of facet  $d$  a who get a positive outcome of value 1. In our example, a facet of older and younger people predicted to get granted a loan. Here  $n'_d^{(1)}$  represents the number of members of facet  $d$  who get a positive predicted outcome and  $n_d$  the is number of members of facet  $d$ .

For binary, multiclass facet, and continuous labels, the DI values range over the interval  $[0, \infty)$ .

- Values less than 1 indicate that facet  $a$  has a higher proportion of predicted positive outcomes than facet  $d$ . This is referred to as *positive bias*.
- A value of 1 indicates demographic parity.
- Values greater than 1 indicate that facet  $d$  has a higher proportion of predicted positive outcomes than facet  $a$ . This is referred to as *negative bias*.

## Difference in Conditional Acceptance (DCAcc)

This metric compares the observed labels to the labels predicted by the model and assesses whether this is the same across facets for predicted positive outcomes. This metric comes close to mimicking human bias in that it quantifies how many more positive outcomes a model predicted (labels  $y'$ ) for a certain facet as compared to what was observed in the training dataset (labels  $y$ ). For example, if there were more acceptances (a positive outcome) for loan applications for a middle-aged group (facet  $a$ ) than predicted by the model based on qualifications as compared to the facet containing other age groups (facet  $d$ ), this might indicate potential bias in the way loans were approved.

The formula for the difference in conditional acceptance:

$$DCAcc = c_a - c_d$$

Where:

- $c_a = n_a^{(1)}/n'_a^{(1)}$  is the ratio of the observed number of positive outcomes of value 1 (acceptances) of facet  $a$  to the predicted number of positive outcome (acceptances) for facet  $a$ .
- $c_d = n_d^{(1)}/n'_d^{(1)}$  is the ratio of the observed number of positive outcomes of value 1 (acceptances) of facet  $d$  to the predicted number of predicted positive outcomes (acceptances) for facet  $d$ .

The DCAcc metric can capture both positive and negative biases that reveal preferential treatment based on qualifications. Consider the following instances of age-based bias on loan acceptances.

#### **Example 1: Positive bias**

Suppose we have dataset of 100 middle-aged people (facet *a*) and 50 people from other age groups (facet *d*) who applied for loans, where the model recommended that 60 from facet *a* and 30 from facet *d* be given loans. So the predicted proportions are unbiased with respect to the DPPL metric, but the observed labels show that 70 from facet *a* and 20 from facet *d* were granted loans. In other words, the model granted loans to 17% more from the middle aged facet than the observed labels in the training data suggested ( $70/60 = 1.17$ ) and granted loans to 33% less from other age groups than the observed labels suggested ( $20/30 = 0.67$ ). The calculation of the DCAcc value quantifies this difference between +17% and -33%. The calculation of the DCAcc value gives the following:

$$\text{DCAcc} = 70/60 - 20/30 = 1/2$$

#### **Example 2: Negative bias**

Suppose we have dataset of 100 middle-aged people (facet *a*) and 50 people from other age groups (facet *d*) who applied for loans, where the model recommended that 60 from facet *a* and 30 from facet *d* be given loans. So the predicted proportions are unbiased with respect to the DPPL metric, but the observed labels show that 50 from facet *a* and 40 from facet *d* were granted loans. In other words, the model granted loans to 17% fewer from the middle aged facet than the observed labels in the training data suggested ( $50/60 = 0.83$ ), and granted loans to 33% more from other age groups than the observed labels suggested ( $40/30 = 1.33$ ). The calculation of the DCAcc value quantifies this difference between -17% and +33%. The calculation of the DCAcc value gives the following:

$$\text{DCAcc} = 50/60 - 40/30 = -1/2$$

Note that you can use DCAcc to help you detect potential (unintentional) biases by humans overseeing the model predictions in a human-in-the-loop setting. Assume, for example, that the predictions  $y'$  by the model were unbiased, but the eventual decision is made by a human (possibly with access to additional features) who can alter the model predictions to generate a new and final version of  $y'$ . The additional processing by the human may unintentionally deny loans to a disproportionate number from one facet. DCAcc can help detect such potential biases.

The range of values for differences in conditional acceptance for binary, multicategory facet, and continuous labels is  $(-\infty, +\infty)$ .

- Positive values occur when the ratio of the observed number of acceptances compared to predicted acceptances for facet *a* is higher than the same ratio for facet *d*. These values indicate a possible bias against the qualified applicants from facet *d*. The larger the difference of the ratios, the more extreme the apparent bias.
- Values near zero occur when the ratio of the observed number of acceptances compared to predicted acceptances for facet *a* is similar to the ratio for facet *d*. These values indicate that predicted acceptance rates are consistent with the observed values in the labeled data and that qualified applicants from both facets are being accepted in a similar way.
- Negative values occur when the ratio of the observed number of acceptances compared to predicted acceptances for facet *a* is less than that ratio for facet *d*. These values indicate a possible bias against the qualified applicants from facet *a*. The more negative the difference in the ratios, the more extreme the apparent bias.

## Difference in Conditional Rejection (DCR)

This metric compares the observed labels to the labels predicted by the model and assesses whether this is the same across facets for negative outcomes (rejections). This metric comes close to mimicking human bias, in that it quantifies how many more negative outcomes a model granted (predicted labels  $y'$ ) to a certain facet as compared to what was suggested by the labels in the training dataset (observed

labels  $y$ ). For example, if there were more rejections (a negative outcome) for loan applications for a middle-aged group (facet  $a$ ) than predicted by the model based on qualifications as compared to the facet containing other age groups (facet  $d$ ), this might indicate potential bias in the way loans were rejected.

The formula for the difference in conditional acceptance:

$$DCR = r_d - r_a$$

Where:

- $r_d = n_d^{(0)} / n_d^{(0)}$  is the ratio of the observed number of negative outcomes of value 1 (rejections) of facet  $d$  to the predicted number of negative outcome (rejections) for facet  $d$ .
- $r_a = n_a^{(0)} / n_a^{(0)}$  is the ratio of the observed number of negative outcomes of value 0 (rejections) of facet  $a$  to the predicted number of negative outcome of value 0 (rejections) for facet  $a$ .

The DCR metric can capture both positive and negative biases that reveal preferential treatment based on qualifications. Consider the following instances of age-based bias on loan rejections.

#### **Example 1: Positive bias**

Suppose we have dataset of 100 middle-aged people (facet  $a$ ) and 50 people from other age groups (facet  $d$ ) who applied for loans, where the model recommended that 60 from facet  $a$  and 30 from facet  $d$  be rejected for loans. So the predicted proportions are unbiased by the DPPL metric, but the observed labels show that 50 from facet  $a$  and 40 from facet  $d$  were rejected. In other words, the model rejected loans for 17% fewer from the middle aged facet than the observed labels in the training data suggested ( $50/60 = 0.83$ ), and rejected loans for 33% more from other age groups than the observed labels suggested ( $40/30 = 1.33$ ). The calculation of the DCR value quantifies this difference between -17% and +33%.

$$DCR = 40/30 - 50/60 = 1/2$$

#### **Example 2: Negative bias**

Suppose we have dataset of 100 middle-aged people (facet  $a$ ) and 50 people from other age groups (facet  $d$ ) who applied for loans, where the model recommended that 60 from facet  $a$  and 30 from facet  $d$  be rejected for loans. So the predicted proportions are unbiased by the DPPL metric, but the observed labels show that 70 from facet  $a$  and 20 from facet  $d$  were rejected. In other words, the model rejected loans for 17% more from the middle aged facet than the observed labels in the training data suggested ( $70/60 = 1.17$ ), and rejected loans for 33% fewer from other age groups than the observed labels suggested ( $20/30 = 0.67$ ). The calculation of the DCR value quantifies this difference between 17% and -33%.

$$DCR = 20/30 - 70/60 = -1/2$$

The range of values for differences in conditional rejection for binary, multicategory facet, and continuous labels is  $(-\infty, +\infty)$ .

- Positive values occur when the ratio of the observed number of rejections compared to predicted rejections for facet  $d$  is greater than that ratio for facet  $a$ . These values indicate a possible bias against the qualified applicants from facet  $d$ . The larger the value of DCR metric, the more extreme the apparent bias.
- Values near zero occur when the ratio of the observed number of rejections compared to predicted acceptances for facet  $a$  is similar to the ratio for facet  $d$ . These values indicate that predicted rejections rates are consistent with the observed values in the labeled data and that the qualified applicants from both facets are being rejected in a similar way.
- Negative values occur when the ratio of the observed number of rejections compared to predicted rejections for facet  $d$  is less than that ratio for facet  $a$ . These values indicate a possible bias against the

qualified applicants from facet  $a$ . The larger magnitude of the negative DCR metric, the more extreme the apparent bias.

## Recall Difference (RD)

The recall difference (RD) metric is the difference in recall of the model between the favored facet  $a$  and disfavored facet  $d$ . Any difference in these recalls is a potential form of bias. Recall is the true positive rate (TPR), which measures how often the model correctly predicts the cases that should receive a positive outcome. Recall is perfect for a facet if all of the  $y=1$  cases are correctly predicted as  $y'=1$  for that facet. Recall is greater when the model minimizes false negatives known as the Type II error. For example, how many of the people in two different groups (facets  $a$  and  $d$ ) that should qualify for loans are detected correctly by the model? If the recall rate is high for lending to facet  $a$ , but low for lending to facet  $d$ , the difference provides a measure of this bias against the group belonging to facet  $d$ .

The formula for difference in the recall rates for facets  $a$  and  $d$ :

$$RD = TP_a/(TP_a + FN_a) - TP_d/(TP_d + FN_d) = TPR_a - TPR_d$$

Where:

- $TP_a$  are the true positives predicted for facet  $a$ .
- $FN_a$  are the false negatives predicted for facet  $a$ .
- $TP_d$  are the true positives predicted for facet  $d$ .
- $FN_d$  are the false negatives predicted for facet  $d$ .
- $TPR_a = TP_a/(TP_a + FN_a)$  is the recall for facet  $a$ . or its true positive rate.
- $TPR_d = TP_d/(TP_d + FN_d)$  is the recall for facet  $d$ . or its true positive rate.

For example, consider the following confusion matrices for facets  $a$  and  $d$ .

### Confusion Matrix for the Favored Facet a

Class a predictions	Actual outcome 0	Actual outcome 1	Total
0	20	5	25
1	10	65	75
Total	30	70	100

### Confusion Matrix for the Disfavored Facet d

Class d predictions	Actual outcome 0	Actual outcome 1	Total
0	18	7	25
1	5	20	25
Total	23	27	50

The value of the recall difference is  $RD = 65/70 - 20/27 = 0.93 - 0.74 = 0.19$  which indicates a bias against facet  $d$ .

The range of values for the recall difference between facets  $a$  and  $d$  for binary and multiclass classification is  $[-1, +1]$ . This metric is not available for the case of continuous labels.

- Positive values are obtained when there is higher recall for facet  $a$  than for facet  $d$ . This suggests that the model finds more of the true positives for facet  $a$  than for facet  $d$ , which is a form of bias.
- Values near zero indicate that the recall for facets being compared is similar. This suggests that the model finds about the same number of true positives in both of these facets and is not biased.
- Negative values are obtained when there is higher recall for facet  $d$  than for facet  $a$ . This suggests that the model finds more of the true positives for facet  $d$  than for facet  $a$ , which is a form of bias.

## Difference in Acceptance Rates (DAR)

The difference in acceptance rates (DAR) metric is the difference in the ratios of the true positive (TP) predictions to the observed positives (TP + FP) for facets  $a$  and  $d$ . This metric measures the difference in the precision of the model for predicting acceptances from these two facets. Precision measures the fraction of qualified candidates from the pool of qualified candidates that are identified as such by the model. If the model precision for predicting qualified applicants diverges between the facets, this is a bias and its magnitude is measured by the DAR.

The formula for difference in acceptance rates between facets  $a$  and  $d$ :

$$\text{DAR} = \text{TP}_a / (\text{TP}_a + \text{FP}_a) - \text{TP}_d / (\text{TP}_d + \text{FP}_d)$$

Where:

- $\text{TP}_a$  are the true positives predicted for facet  $a$ .
- $\text{FP}_a$  are the false positives predicted for facet  $a$ .
- $\text{TP}_d$  are the true positives predicted for facet  $d$ .
- $\text{FP}_d$  are the false positives predicted for facet  $d$ .

For example, suppose the model accepts 70 middle-aged applicants (facet  $a$ ) for a loan (predicted positive labels) of whom only 35 are actually accepted (observed positive labels). Also suppose the model accepts 100 applicants from other age demographics (facet  $d$ ) for a loan (predicted positive labels) of whom only 40 are actually accepted (observed positive labels). Then  $\text{DAR} = 35/70 - 40/100 = 0.10$ , which indicates a potential bias against qualified people from the second age group (facet  $d$ ).

The range of values for DAR for binary, multicategory facet, and continuous labels is  $[-1, +1]$ .

- Positive values occur when the ratio of the predicted positives (acceptances) to the observed positive outcomes (qualified applicants) for facet  $a$  is larger than the same ratio for facet  $d$ . These values indicate a possible bias against the disfavored facet  $d$  caused by the occurrence of relatively more false positives in facet  $d$ . The larger the difference in the ratios, the more extreme the apparent bias.
- Values near zero occur when the ratio of the predicted positives (acceptances) to the observed positive outcomes (qualified applicants) for facets  $a$  and  $d$  have similar values indicating the observed labels for positive outcomes are being predicted with equal precision by the model.
- Negative values occur when the ratio of the predicted positives (acceptances) to the observed positive outcomes (qualified applicants) for facet  $d$  is larger than the ratio for facet  $a$ . These values indicate a possible bias against the favored facet  $a$  caused by the occurrence of relatively more false positives in facet  $a$ . The more negative the difference in the ratios, the more extreme the apparent bias.

## Difference in Rejection Rates (DRR)

The difference in rejection rates (DRR) metric is the difference in the ratios of the true negative (TN) predictions to the observed negatives (TN + FN) for facets  $a$  and  $d$ . This metric measures the difference in the precision of the model for predicting rejections from these two facets. Precision measures the fraction of unqualified candidates from the pool of unqualified candidates that are identified as such by

the model. If the model precision for predicting unqualified applicants diverges between the facets, this is a bias and its magnitude is measured by the DRR.

The formula for difference in rejection rates between facets  $a$  and  $d$ :

$$\text{DRR} = \text{TN}_d / (\text{TN}_d + \text{FN}_d) - \text{TN}_a / (\text{TN}_a + \text{FN}_a)$$

Where:

- $\text{TN}_d$  are the true negatives predicted for facet  $d$ .
- $\text{FN}_d$  are the false negatives predicted for facet  $d$ .
- $\text{TN}_a$  are the true negatives predicted for facet  $a$ .
- $\text{FN}_a$  are the false negatives predicted for facet  $a$ .

For example, suppose the model rejects 100 middle-aged applicants (facet  $a$ ) for a loan (predicted negative labels) of whom 80 are actually unqualified (observed negative labels). Also suppose the model accepts 50 applicants from other age demographics (facet  $d$ ) for a loan (predicted negative labels) of whom only 40 are actually unqualified (observed negative labels). Then  $\text{DRR} = 40/50 - 80/100 = 0$ , so no bias is indicated. When both DAR and DRR are zero, it satisfies a condition known as *equalized odds*.

The range of values for DRR for binary, multicategory facet, and continuous labels is  $[-1, +1]$ .

- Positive values occur when the ratio of the predicted negatives (rejections) to the observed negative outcomes (unqualified applicants) for facet  $d$  is larger than the same ratio for facet  $a$ . These values indicate a possible bias against the favored facet  $a$  caused by the occurrence of relatively more false negatives in facet  $a$ . The larger the difference in the ratios, the more extreme the apparent bias.
- Values near zero occur when the ratio of the predicted negatives (rejections) to the observed negative outcomes (unqualified applicants) for facets  $a$  and  $d$  have similar values, indicating the observed labels for negative outcomes are being predicted with equal precision by the model.
- Negative values occur when the ratio of the predicted negatives (rejections) to the observed negative outcomes (unqualified applicants) for facet  $a$  is larger than the ratio for facet  $d$ . These values indicate a possible bias against the disfavored facet  $d$  caused by the occurrence of relatively more false positives in facet  $d$ . The more negative the difference in the ratios, the more extreme the apparent bias.

## Accuracy Difference (AD)

Accuracy difference (AD) metric is the difference between the prediction accuracy for different facets. This metric determines whether the classification by the model is more accurate for one facet than the other. AD indicates whether one facet incurs a greater proportion of Type I and Type II errors. But it cannot differentiate between Type I and Type II errors. For example, the model may have equal accuracy for different age demographics, but the errors may be mostly false positives (Type I errors) for one age-based group and mostly false negatives (Type II errors) for the other.

Also, if loan approvals are made with much higher accuracy for a middle-aged demographic (facet  $a$ ) than for another age-based demographic (facet  $d$ ), either a greater proportion of qualified applicants in the second group are denied a loan (FN) or a greater proportion of unqualified applicants from that group get a loan (FP) or both. This can lead to within group unfairness for the second group, even if the proportion of loans granted is nearly the same for both age-based groups, which is indicated by a DPPL value that is close to zero.

The formula for AD metric is the difference between the prediction accuracy for facet  $a$ ,  $\text{ACC}_a$ , minus that for facet  $d$ ,  $\text{ACC}_d$ :

$$\text{AD} = \text{ACC}_a - \text{ACC}_d$$

Where:

- $ACC_a = (TP_a + TN_a) / (TP_a + TN_a + FP_a + FN_a)$ 
  - $TP_a$  are the true positives predicted for facet  $a$
  - $TN_a$  are the true negatives predicted for facet  $a$
  - $FP_a$  are the false positives predicted for facet  $a$
  - $FN_a$  are the false negatives predicted for facet  $a$
- $ACC_d = (TP_d + TN_d) / (TP_d + TN_d + FP_d + FN_d)$ 
  - $TP_d$  are the true positives predicted for facet  $d$
  - $TN_d$  are the true negatives predicted for facet  $d$
  - $FP_d$  are the false positives predicted for facet  $d$
  - $FN_d$  are the false negatives predicted for facet  $d$

For example, suppose a model approves loans to 70 applicants from facet  $a$  of 100 and rejected the other 30. 10 should not have been offered the loan ( $FP_a$ ) and 60 were approved that should have been ( $TP_a$ ). 20 of the rejections should have been approved ( $FN_a$ ) and 10 were correctly rejected ( $TN_a$ ). The accuracy for facet  $a$  is as follows:

$$ACC_a = (60 + 10) / (60 + 10 + 20 + 10) = 0.7$$

Next, suppose a model approves loans to 50 applicants from facet  $d$  of 100 and rejected the other 50. 10 should not have been offered the loan ( $FP_d$ ) and 40 were approved that should have been ( $TP_d$ ). 40 of the rejections should have been approved ( $FN_d$ ) and 10 were correctly rejected ( $TN_d$ ). The accuracy for facet  $a$  is determined as follows:

$$ACC_d = (40 + 10) / (40 + 10 + 40 + 10) = 0.5$$

The accuracy difference is thus  $AD = ACC_a - ACC_d = 0.7 - 0.5 = 0.2$ . This indicates there is a bias against facet  $d$  as the metric is positive.

The range of values for  $AD$  for binary and multicategory facet labels is  $[-1, +1]$ .

- Positive values occur when the prediction accuracy for facet  $a$  is greater than that for facet  $d$ . It means that facet  $d$  suffers more from some combination of false positives (Type I errors) or false negatives (Type II errors). This means there is a potential bias against the disfavored facet  $d$ .
- Values near zero occur when the prediction accuracy for facet  $a$  is similar to that for facet  $d$ .
- Negative values occur when the prediction accuracy for facet  $d$  is greater than that for facet  $a$ . It means that facet  $a$  suffers more from some combination of false positives (Type I errors) or false negatives (Type II errors). This means there is a bias against the favored facet  $a$ .

## Treatment Equality (TE)

The treatment equality (TE) is the difference in the ratio of false positives to false negatives between facets  $a$  and  $d$ . The main idea of this metric is to assess whether, even if the accuracy across groups is the same, is it the case that errors are more harmful to one group than another? Error rate comes from the total of false positives and false negatives, but the breakdown of these two maybe very different across facets. TE measures whether errors are compensating in the similar or different ways across facets.

The formula for the treatment equality:

$$TE = FP_a/FN_a - FP_d/FN_d$$

Where:

- $FP_a$  are the false positives predicted for facet  $a$ .
- $FN_a$  are the false negatives predicted for facet  $a$ .

- $FP_d$  are the false positives predicted for facet  $d$ .
- $FN_d$  are the false negatives predicted for facet  $d$ .

Note the metric becomes unbounded if  $FN_a$  or  $FN_d$  is zero.

For example, suppose that there are 100 loan applicants from facet  $a$  and 50 from facet  $d$ . For facet  $a$ , 8 were wrongly denied a loan ( $FN_a$ ) and another 6 were wrongly approved ( $FP_a$ ). The remaining predictions were true, so  $TP_a + TN_a = 86$ . For facet  $d$ , 5 were wrongly denied ( $FN_d$ ) and 2 were wrongly approved ( $FP_d$ ). The remaining predictions were true, so  $TP_d + TN_d = 43$ . The ratio of false positives to false negatives equals  $6/8 = 0.75$  for facet  $a$  and  $2/5 = 0.40$  for facet  $d$ . Hence  $TE = 0.75 - 0.40 = 0.35$ , even though both facets have the same accuracy:

$$ACC_a = (86)/(68+ 8 + 6) = 0.86$$

$$ACC_d = (43)/(43 + 5 + 2) = 0.86$$

The range of values for differences in conditional rejection for binary and multiclass facet labels is  $(-\infty, +\infty)$ . The TE metric is not defined for continuous labels. The interpretation of this metric depends on the relative importance of false positives (Type I error) and false negatives (Type II error).

- Positive values occur when the ratio of false positives to false negatives for facet  $a$  is greater than that for facet  $d$ .
- Values near zero occur when the ratio of false positives to false negatives for facet  $a$  is similar to that for facet  $d$ .
- Negative values occur when the ratio of false positives to false negatives for facet  $a$  is less than that for facet  $d$ .

## Conditional Demographic Disparity in Predicted Labels (CDDPL)

The demographic disparity metric (DDPL) determines whether facet  $d$  has a larger proportion of the predicted rejected labels than of the predicted accepted labels. It enables a comparison of difference in predicted rejection proportion and predicted acceptance proportion across facets. This metric is exactly the same as the pretraining CDD metric except that it is computed off the predicted labels instead of the observed ones. This metric lies in the range  $(-1,+1)$ .

The formula for the demographic disparity predictions for labels of facet  $d$  is as follows:

$$DDPL_d = n'_d^{(0)}/n'^{(0)} - n'_d^{(1)}/n'^{(1)} = P_d^R(y'^0) - P_d^A(y'^1)$$

Where:

- $n'^{(0)} = n'_a^{(0)} + n'_d^{(0)}$  is the number of predicted rejected labels for facets  $a$  and  $d$ .
- $n'^{(1)} = n'_a^{(1)} + n'_d^{(1)}$  is the number of predicted accepted labels for facets  $a$  and  $d$ .
- $P_d^R(y'^0)$  is the proportion of predicted rejected labels (value 0) in facet  $d$ .
- $P_d^A(y'^1)$  is the proportion of predicted accepted labels (value 1) in facet  $d$ .

A conditional demographic disparity in predicted labels (CDDPL) metric that conditions DDPL on attributes that define a strata of subgroups on the dataset is needed to rule out Simpson's paradox. The regrouping can provide insights into the cause of apparent demographic disparities for less favored facets. The classic case arose in the case of Berkeley admissions where men were accepted at a higher rate overall than women. But when departmental subgroups were examined, women were shown to have higher admission rates than men by department. The explanation was that women had applied to departments with lower acceptance rates than men had. Examining the subgroup acceptance rates revealed that women were actually accepted at a higher rate than men for the departments with lower acceptance rates.

The CDDPL metric gives a single measure for all of the disparities found in the subgroups defined by an attribute of a dataset by averaging them. It is defined as the weighted average of demographic disparities in predicted labels (DDPL<sub>i</sub>) for each of the subgroups, with each subgroup disparity weighted in proportion to the number of observations it contains. The formula for the conditional demographic disparity in predicted labels is as follows:

$$CDDPL = (1/n) \cdot \sum_i n_i \cdot DDPL_i$$

Where:

- $\sum_i n_i = n$  is the total number of observations and  $n_i$  is the number of observations for each subgroup.
- $DDPL_i = n_i^{(0)}/n^{(0)} - n_i^{(1)}/n^{(1)} = P_i^R(y^0) - P_i^A(y^1)$  is the demographic disparity in predicted labels for the subgroup.

So the demographic disparity for a subgroup in predicted labels (DDPL<sub>i</sub>) are the difference between the proportion of predicted rejected labels and the proportion of predicted accepted labels for each subgroup.

The range of DDPL values for binary, multiclass, and continuous outcomes is [-1, +1].

- +1: when there are no predicted rejection labels for facet  $a$  or subgroup and no predicted acceptances for facet  $d$  or subgroup.
- Positive values indicate there is a demographic disparity in predicted labels as facet  $d$  or subgroup has a larger proportion of the predicted rejected labels than of the predicted accepted labels. The higher the value the greater the disparity.
- Values near zero indicate there is no demographic disparity on average.
- Negative values indicate there is a demographic disparity in predicted labels as facet  $a$  or subgroup has a larger proportion of the predicted rejected labels than of the predicted accepted labels. The lower the value the greater the disparity.
- -1: when there are no predicted rejection labels for facet  $d$  or subgroup and no predicted acceptances for facet  $a$  or subgroup.

## Counterfactual Fliptest (FT)

The fliptest is an approach that looks at each member of facet  $d$  and assesses whether similar members of facet  $a$  have different model predictions. The members of facet  $a$  are chosen to be  $k$ -nearest neighbors of the observation from facet  $d$ . We assess how many nearest neighbors of the opposite group receive a different prediction, where the flipped prediction can go from positive to negative and vice versa.

The formula for the counterfactual fliptest is the difference in the cardinality of two sets divided by the number of members of facet  $d$ :

$$FT = (F^+ - F^-)/n_d$$

Where:

- $F^+$  = is the number of disfavored facet  $d$  members with an unfavorable outcome whose nearest neighbors in favored facet  $a$  received a favorable outcome.
- $F^-$  = is the number of disfavored facet  $d$  members with a favorable outcome whose nearest neighbors in favored facet  $a$  received an unfavorable outcome.
- $n_d$  is the sample size of facet  $d$ .

The range of values for the counterfactual fliptest for binary and multiclass facet labels is [-1, +1]. For continuous labels, we set a threshold to collapse the labels to binary.

- Positive values occur when the number of unfavorable counterfactual fliptest decisions for the disfavored facet  $d$  exceeds the favorable ones.
- Values near zero occur when the number of unfavorable and favorable counterfactual fliptest decisions balance out.
- Negative values occur when the number of unfavorable counterfactual fliptest decisions for the disfavored facet  $d$  is less than the favorable ones.

## Configure an Amazon SageMaker Clarify Processing Jobs for Fairness and Explainability

This topic describes how to configure an Amazon SageMaker Clarify processing job capable of computing bias metrics and feature attributions for explainability. It is implemented using a specialized SageMaker Clarify container image. Instructions are provided for how to locate and download one of these container images. A brief overview of how SageMaker Clarify works is sketched. The parameters needed to configure the processing job and type of analysis are described. Prerequisites are outlined and some advice about compute resources consumed by SageMaker Clarify processing job is provided.

### Topics

- [Prerequisites \(p. 1840\)](#)
- [Getting Started with a SageMaker Clarify Container \(p. 1840\)](#)
- [How It Works \(p. 1842\)](#)
- [Configure a Processing Job Container's Input and Output Parameters \(p. 1842\)](#)
- [Configure the Analysis \(p. 1843\)](#)

## Prerequisites

Before you begin, you need to meet the following prerequisites:

- You need to provide an input dataset as tabular files in CSV or JSONLines format. The input dataset must include a label column for bias analysis. The dataset should be prepared for machine learning with any pre-processing needed, such as data cleaning or feature engineering, already completed.
- You need to provide a model artifact that supports either the CSV or JSONLines file format as one of its content type inputs. For posttraining bias metrics and explainability, we use the dataset to make inferences with the model artifact. Each row minus the label column must be ready to be used as payload for inferences.
- When creating processing jobs with the SageMaker container image, you need the following:
  - Network isolation must be disabled for the processing job.
  - If the model is in a VPC, the processing job must be in the same VPC as the model.
  - The IAM user/role of the caller must have permissions for SageMaker APIs. We recommend that you use the “`arn:aws:iam::aws:policy/AmazonSageMakerFullAccess`” managed policy.

## Getting Started with a SageMaker Clarify Container

Amazon SageMaker provides prebuilt SageMaker Clarify container images that include the libraries and other dependencies needed to compute bias metrics and feature attributions for explainability. This image has been enabled to run SageMaker [Process Data \(p. 664\)](#) in your account.

The image URIs for the containers are in the following form:

```
<ACCOUNT_ID>.dkr.ecr.<REGION_NAME>.amazonaws.com/sagemaker-clarify-processing:1.0
```

For example:

205585389593.dkr.ecr.us-east-1.amazonaws.com/sagemaker-clarify-processing:1.0

The following table lists the addresses by Amazon Region.

### Docker Images for Pretraining Bias Detection

Region	Image address
us-east-1	205585389593.dkr.ecr.us-east-1.amazonaws.com/sagemaker-clarify-processing:1.0

## How It Works

A SageMaker processing job used the SageMaker Clarify container at several stages in the lifecycle of the machine learning workflow. You can use the SageMaker Clarify container with your datasets and models to compute the following types of analysis:

- pretraining bias metrics
- posttraining bias metrics
- SHAP values for explainability

You can control which of these analyses are computed when you configure the processing job. For pretraining bias metrics, you need to provide the dataset. You can compute posttraining bias metrics and explainability after your model has been trained by providing the dataset and model name. You must configure the necessary parameters in the form of a JSON configuration file and provide this as an input to the processing job.

After the processing job completes, the result of the analyses is saved in the output location specified in the `ProcessingOutput` parameters of the processing job. You can then download it from there and view the outputs or you can view the results in Studio if you have run a notebook there.

In order to compute posttraining bias metrics and SHAP values, the computation needs to get inferences for the model name provided. To accomplish this, the processing job creates an ephemeral endpoint with the model name, known as a *shadow endpoint*. The processing job deletes the shadow endpoint after the computations are completed.

At a high level, the processing job completes the following steps:

1. Validate inputs and parameters.
2. Create the shadow endpoint.
3. Compute pretraining bias metrics.
4. Compute posttraining bias-metrics.
5. Compute local and global feature attributions.
6. Delete shadow endpoint.
7. Generate output files.

## Configure a Processing Job Container's Input and Output Parameters

The Processing Job requires that you specify the following input parameters: a dataset files with input name "dataset" as S3 object or prefix, and an analysis configuration file with input name "analysis\_config" as an S3 object. The job also requires an output parameter: the output location as an S3 prefix.

You can create and run a processing job with SageMaker [CreateProcessingJob](#) API using the Amazon SDK or CLI or [SageMaker Python SDK](#).

Using SageMaker Python SDK, create a Processor using the SageMaker Clarify container image URI:

```
from sagemaker import clarify
clarify_processor = clarify.SageMakerClarifyProcessor(role=role,
                                                       instance_count=1,
                                                       instance_type='ml.c5.xlarge',
                                                       max_runtime_in_seconds=1200,
                                                       volume_size_in_gb=100)
```

Then, you must also provide the input and output parameters for the SageMakerClarifyProcessor. If you provide the "dataset\_uri", the dataset input is optional.

```
dataset_path = "s3://my_bucket/my_folder/train.csv"
analysis_config_path = "s3://my_bucket/my_folder/analysis_config.json"
analysis_result_path = "s3://my_bucket/my_folder/output"

analysis_config_input = ProcessingInput(
    input_name="analysis_config",
    source=analysis_config_path,
    destination="/opt/ml/processing/input/config",
    s3_data_type="S3Prefix",
    s3_input_mode="File",
    s3_compression_type="None")
dataset_input = ProcessingInput(
    input_name="dataset",
    source=dataset_path,
    destination="/opt/ml/processing/input/data",
    s3_data_type="S3Prefix",
    s3_input_mode="File",
    s3_compression_type="None")
analysis_result_output = ProcessingOutput(
    source="/opt/ml/processing/output",
    destination=analysis_result_path,
    output_name="analysis_result",
    s3_upload_mode="EndOfJob")
```

## Configure the Analysis

Parameters for the analysis configuration must be provided in a JSON file named "analysis\_config.json". The path must be provided in the `ProcessingInput` parameter named "analysis\_config". Examples of analysis configuration files are provided below. In this JSON configuration file, you specify the following parameters:

- "version" – (Optional) Schema version of the configuration file. The latest supported version is used if not provided.
- "dataset\_type" – Format of the dataset. Valid values are "text/csv" for CSV and "application/jsonlines" for JSON Lines.
- "dataset\_uri" – (Optional) Dataset S3 prefix/object URI (if not given as `ProcessingInput`). If it is a prefix, then processing job recursively collects all S3 files under the prefix.
- "headers" – (Optional) A list of column names in the dataset. If the `dataset_type` is "application/jsonlines" and "label" is specified, then the last header shall be the header of label column.
- "label" – (Optional) Target attribute for the model to be used for *bias metrics* specified as a column name or index if the dataset format is CSV or as JSONPath if the dataset format is JSONLines.
- "probability\_threshold" – (Optional) A float value to indicate the threshold to select the binary label in the case of binary classification. The default value is 0.5.

- "features" – (Optional) JSONPath for locating the feature columns for bias metrics if the dataset format is JSONLines.
- "label\_values\_or\_threshold" – (Optional) List of label values or threshold to indicate positive outcome used for bias metrics.
- "facet" – (Optional) A list of features that are sensitive attributes, referred to as facets, to be used for bias metrics in the form of pairs to include the following:
  - "name\_or\_index" – Facet column name or index.
  - "value\_or\_threshold" – (Optional) List of values or threshold that the facet column can take which indicates the sensitive group, i.e. the group that is used to measure bias against. If not provided, bias metrics are computed as one group versus all for every unique value. If the facet column is numeric this threshold value is applied as the lower bound to select the sensitive group.
- "group\_variable" – (Optional) A column name or index to indicate group variable to be used for the *bias metric Conditional Demographic Disparity*.
- "methods" – A list of methods and their parameters for the analyses and reports. If any section is omitted then it is not computed.
  - "pre\_training\_bias" – (Optional) Section on pretraining bias metrics.
    - "methods" – A list of pretraining metrics to be computed.
  - "post\_training\_bias" – (Optional) Section on posttraining bias metrics.
    - "methods" – A list of posttraining metrics to be computed.
  - "shap" – (Optional) Section on SHAP value computation.
    - "baseline" – A list of rows (at least one) or S3 object URI to be used as the baseline dataset (also known as a background dataset) in the Kernel SHAP algorithm. The format should be the same as the dataset format. Each row should contain only the feature columns/values and omit the label column/values
    - "num\_samples" – Number of samples to be used in the Kernel SHAP algorithm. This number determines the size of the generated synthetic dataset to compute the SHAP values.
    - "agg\_method" – Aggregation method for global SHAP values. Valid values are as follows:
      - "mean\_abs" – Mean of absolute SHAP values for all instances.
      - "median" – Median of SHAP values for all instances.
      - "mean\_sq" – Mean of squared SHAP values for all instances.
    - "use\_logit" – (Optional) Boolean value to indicate if logit function is to be applied to the model predictions. The default value is "false". If "use\_logit" is "true" then the SHAP values have log-odds units.
    - "save\_local\_shap\_values" – (Optional) Boolean value to indicate if local SHAP values are to be saved in the output location. Default is "true".
  - "predictor" – (Optional) Section on model parameters, required if "shap" and "post\_training\_bias" sections are present.
    - "model\_name" – Model name (as created by CreateModel API with container mode as SingleModel).
    - "instance\_type" – Instance type for the shadow endpoint.
    - "initial\_instance\_count" – Instance count for the shadow endpoint.
    - "content\_type" – (Optional) The model input format to be used for getting inferences with the shadow endpoint. Valid values are "text/csv" for CSV and "application/jsonlines". The default value is the same as dataset format.
    - "accept\_type" – (Optional) The model *output* format to be used for getting inferences with the shadow endpoint. Valid values are "text/csv" for CSV and "application/jsonlines". The default value is the same as content\_type.
    - "label" – (Optional) Index or JSONPath location in the model output for the target attribute to be used bias metrics. In CSV accept\_type case, if it is not provided then assume that the model output is a single numeric value corresponding to score or probability.

- "probability" – (Optional) Index or JSONPath location in the model output for probabilities or scores to be used for explainability. For example, if the model output is JSONLines with a list of labels and probabilities, then for bias methods, the label that corresponds to the maximum probability is selected for bias computations. For explainability method, currently all probabilities are explained.
- "label\_headers" – (Optional) A list of values that the "label" takes in the dataset that describe which label value each of the scores returned by the model endpoint correspond to. It is used to extract the label value with the highest score as predicted label for bias computations.
- "content\_template" – (Optional) A template string to be used to construct the model input from dataset instances. It is only used when "content\_type" is "application/jsonlines". The template should have one and only one placeholder, \$features, which is replaced by features list at runtime. For example, given "content\_template": "{\"myfeatures\":\$features}", if an instance (no label) is 1,2,3 then model input becomes JSONLine '{"myfeatures": [1,2,3]}'.
- "report" – (Optional) Section on report parameters. A report is generated if this section is present.
- "name" – (Optional) Filename prefix for the report notebook and PDF file. The default name is "report".
- "title" – (Optional) Title string for the report notebook and PDF file. The default title is "SageMaker Analysis Report".

## Example Analysis Configuration JSON File for a CSV Dataset

```
{
  "dataset_type": "text/csv",
  "headers": [
    "feature_0",
    "feature_1",
    "feature_2",
    "feature_3",
    "target"
  ],
  "label": "target",
  "label_values_or_threshold": [1],
  "probability_threshold": 0.7,
  "facet": [
    {
      "name_or_index": "feature_1",
      "value_or_threshold": [1]
    },
    {
      "name_or_index": "feature_2",
      "value_or_threshold": [0.7]
    }
  ],
  "group_variable": "feature_3",
  "methods": {
    "shap": {
      "baseline": [
        [
          "yes",
          3,
          0.9,
          1
        ]
      ],
      "num_samples": 1000,
      "agg_method": "mean",
      "use_logit": true,
      "save_local_shap_values": true
    },
  }
}
```

```

    "pre_training_bias": {
        "methods": "all"
    },
    "post_training_bias": {
        "methods": "all"
    },
    "report": {
        "name": "report",
        "title": "Analysis Report"
    }
},
"predictor": {
    "model_name": "my_model",
    "instance_type": "ml.m5.xlarge",
    "initial_instance_count": 1,
    "content_type": "text/csv",
    "accept_type": "text/csv",
    "label": 0,
    "probability": 1
}
}

```

Model output as CSV is as follows:

```
Current,"[0.028986845165491104, 0.8253824710845947, 0.028993206098675728,  
0.02898673340678215, 0.029557107016444206, 0.0290389321744442, 0.02905467338860035]"
```

Corresponding predictor configuration is as follows:

```

"predictor": {
    ...,
    "accept_type": "text/csv",
    "label": 0,
    "probability": 1,
    ...
}

```

## Example Analysis Configuration JSON File for a JSONLines Dataset

```

{
    "dataset_type": "application/jsonlines",
    "dataset_uri": "s3://my_bucket/my_folder/dataset.jsonl",
    "headers": ["Label", "Feature1", "Feature2"],
    "label": "data.label",
    "features": "data.features.values",
    "facet": [
        {
            "name_or_index": "Feature1",
            "value_or_threshold": [1,5]
        },
        {
            "name_or_index": "Feature2",
            "value_or_threshold": [2,6]
        }
    ],
    "methods": {
        "shap": {
            "baseline": [
                {"data":{"features":{"values":[9,10]},"label":0}},
                {"data":{"features":{"values":[11,12]},"label":1}}
            ]
        }
    }
}

```

```
        },
        "predictor": {
            "model_name": "my_jsonl_model",
            "instance_type": "ml.m5.xlarge",
            "initial_instance_count": 1
        }
    }
```

Dataset as S3 prefix is as follows:

```
"dataset_uri": "s3://my_bucket/my_folder"
```

Dataset as S3 object is as follows:

```
"dataset_uri": "s3://my_bucket/my_folder/train.csv"
```

Baseline as S3 object is as follows:

```
"baseline": "s3://my_bucket/my_folder/baseline.csv"
```

Model output as JSONLines is as follows:

```
{"predicted_label": "Current", "score": "[0.028986845165491104, 0.8253824710845947,
0.028993206098675728, 0.02898673340678215, 0.029557107016444206, 0.0290389321744442,
0.02905467338860035]"}
```

Corresponding predictor configuration is as follows:

```
"predictor": {
    ...
    "accept_type": "application/jsonlines",
    "label": "predicted_label",
    "probability": "score",
    ...
}
```

## Run SageMaker Clarify Processing Jobs for Bias Analysis and Explainability

You use SageMaker Clarify processing jobs to analyze potential sources of bias in your training data and to check your trained model for bias. For the procedure to analyze the data in SageMaker Studio, see [Generate Reports for Bias in Pretraining Data in SageMaker Studio \(p. 572\)](#). The focus here is on posttraining bias metric and SHAP values for explainability. Model predictions can be a source of bias (for example, if they make predictions that more frequently produce a negative result for one group than another). SageMaker Clarify is integrated with SageMaker Experiments so that after a model has been trained, you can identify attributes you would like to check for bias (for example, income). SageMaker runs a set of algorithms to check the trained model and provides you with a visual report on the different types of bias for each attribute, such as whether high-income earners receive more positive predictions compared to low-income earners.

### Topics

- [Compute Resources Required for SageMaker Clarify Processing Jobs \(p. 1848\)](#)
- [Running the Processing Job \(p. 1848\)](#)
- [Get the Analysis Results \(p. 1849\)](#)

## Compute Resources Required for SageMaker Clarify Processing Jobs

Take the following into consideration when determining the compute resources you need to run SageMaker Clarify processing jobs:

- Processing jobs can take several minutes or more to complete.
- Computing explanations can be more time intensive than the actual inference. This includes the time to launch compute resources.
- Computing explanations can be more compute intensive than the actual inference. Review and monitor the charges you may incur from using SageMaker resources. For more information, see [Amazon SageMaker Pricing](#).

## Running the Processing Job

For an example notebook with instructions on how to run a SageMaker Clarify processing job in Studio to detect posttraining model bias, see [Explainability and bias detection with Amazon SageMaker Clarify](#).

If you need instructions on how to open a notebook in Amazon SageMaker Studio, see [Create or Open an Amazon SageMaker Studio Notebook \(p. 79\)](#). The following code samples are taken from the example notebook listed previously.

After you have trained your model, instantiate the SageMaker Clarify processor using the following command:

```
from sagemaker import clarify
clarify_processor = clarify.SageMakerClarifyProcessor(role=role,
                                                       instance_count=1,
                                                       instance_type='ml.c4.xlarge',
                                                       sagemaker_session=session)
```

Next, configure the input dataset, where to store the output, the label column targeted with a `DataConfig` object, specify information about your trained model with `ModelConfig`, and provide information about the formats of your predictions with `ModelPredictedLabelConfig`.

```
bias_report_output_path = 's3://{}//{}//clarify-bias'.format(bucket, prefix)
bias_data_config = clarify.DataConfig(s3_data_input_path=train_uri,
                                      s3_output_path=bias_report_output_path,
                                      label='Target',
                                      headers=training_data.columns.to_list(),
                                      dataset_type='text/csv')

model_config = clarify.ModelConfig(model_name=model_name,
                                    instance_type='ml.c5.xlarge',
                                    instance_count=1,
                                    accept_type='text/csv')

predictions_config = clarify.ModelPredictedLabelConfig(probability_threshold=0.8)
```

Use `BiasConfig` to provide information on which columns contain the facets (sensitive groups, `Sex`), what the sensitive features (`facet_values_or_threshold`) might be, and what the desirable outcomes are (`label_values_or_threshold`).

```
bias_config = clarify.BiasConfig(label_values_or_threshold=[1],
                                 facet_name='Sex',
                                 facet_values_or_threshold=[0])
```

You can run both the pretraining and posttraining analysis in the processing job at the same time with `run_bias()`.

```
clarify_processor.run_bias(data_config=bias_data_config,
                           bias_config=bias_config,
                           model_config=model_config,
                           model_predicted_label_config=predictions_config,
                           pre_training_methods='all',
                           post_training_methods='all')
```

View the results in Studio or download them from the `bias_report_output_path` S3 bucket.

## Get the Analysis Results

After the processing job is finished, you can download the output files to inspect or visualize the results in Studio. The output directory contains the following files:

- `analysis.json` – Bias metrics and SHAP values in JSON format.
- `report.ipynb` – Static notebook to visualize the bias metrics and SHAP values.
- `explanations_shap/out.csv` – Local (per-instance) SHAP values for each row in the dataset in the same format as input dataset. On each row, the output file contains SHAP values for each feature and the predicted label.

In the analysis JSON file, the bias metrics and SHAP values are organized into three separate sections.

```
{
  "explanations": { . . . }
  "pre_training_bias_metrics": { . . . }
  "post_training_bias_metrics": { . . . }
}
```

SHAP values are in the “`explanations`” section. Values correspond to the global SHAP value for each feature column.

```
"explanations": {
    "kernel_shap": {
        "label0": {
            "global_shap_values": {
                "feature_0": 0.022486410860333206,
                "feature_1": 0.007381025261958729,
                "feature_2": 0.006843906804137847
            },
            "expected_value": 0.508233428001
        }
    }
}
```

The bias metrics are in the pretraining and posttraining bias metrics sections.

```
{
  "post_training_bias_metrics": {
    "label": "target",
    "label_value_or_threshold": "1",
    "facets": {
      "feature_2": [
        {
          "value_or_threshold": "1",
          "metrics": [

```

```
{  
    "name": "DI",  
    "description": "Disparate Impact (DI)",  
    "value": 0.711340206185567  
},  
{  
    "name": "DCR",  
    "description": "Difference in Conditional Rejections (DCR)",  
    "value": -0.34782608695652184  
}  
{ . . . }  
]  
}  
}  
}
```

For more information on bias metrics and SHAP values and how to interpret them, see the [Amazon AI Fairness and Explainability Whitepaper](#).

A bar chart of top SHAP values and tables with the bias metrics are provided in the report notebook.

## Troubleshoot SageMaker Clarify Processing Jobs

If you encounter failures with SageMaker Clarify processing jobs, consult the following scenarios to help identify the issue.

### Note

The failure reason and exit message are intended to contain descriptive messages and exceptions, if encountered, during the run. One common reason is invalid or missing parameters. If you encounter unclear, confusing, or misleading messages or are unable to find a solution, submit feedback.

### Topics

- [Processing job fails to finish \(p. 1850\)](#)
- [Processing job finishes without results and you get a CloudWatch warning message \(p. 1851\)](#)
- [Error message for invalid analysis configuration \(p. 1851\)](#)
- [Bias metric computation fails for several or all metrics \(p. 1851\)](#)
- [Mismatch between analysis config and dataset/model input/output \(p. 1851\)](#)
- [Model returns 500 Internal Server Error or container falls back to per-record predictions due to model error \(p. 1852\)](#)
- [Execution role is invalid \(p. 1852\)](#)
- [Failed to download data \(p. 1852\)](#)
- [Could not connect to SageMaker \(p. 1852\)](#)

## Processing job fails to finish

If the processing job fails to finish, you can try the following:

- Inspect the job logs directly in the notebook where you ran the job in. The job logs are located in the output of the notebook cell where you initiated the run.
- Inspect the job logs in CloudWatch.
- Add the following line in your notebook to describe the last processing job and look for the failure reason and exit message:
  - `clarify_processor.jobs[-1].describe()`

- Execute the following Amazon CLI command to describe the processing job and look for the failure reason and exit message:
  - `aws sagemaker describe-processing-job --processing-job-name <processing-job-id>`

## Processing job finishes without results and you get a CloudWatch warning message

If the processing job finishes but no results are found and a warning message is found in the CloudWatch logs that says "Signal 15 received, cleaning up", this is an indication that the job was stopped either due to a customer request that called the `StopProcessingJob` API or that the job ran out of time allotted for its completion. In the later case, check the maximum runtime in the job configuration (`max_runtime_in_seconds`) and increase it as needed.

## Error message for invalid analysis configuration

- If you get the error message "Unable to load analysis configuration as JSON.", this means that the analysis configuration input file for the processing job does not contain a valid JSON object. Check the validity of the JSON object using a JSON linter.
- If you get the error message "Analysis configuration schema validation error.", this means that the analysis configuration input file for the processing job contains unknown fields or invalid types for some field values. Review the configuration parameters in the file and cross-check them with the parameters listed in the [configuration specification](#) file.

## Bias metric computation fails for several or all metrics

If you receive one of the following error messages "No Label values are present in the predicted Label Column, Positive Predicted Index Series contains all False values." or "Predicted Label Column series datatype is not the same as Label Column series.", try the following:

- Check that the correct dataset is being used.
- Check whether the dataset size is too small; whether, for example, it contains only a few rows. This may cause the model outputs to have the same value or the data type is inferred incorrectly.
- Check if the label or facet is treated as continuous or categorical. SageMaker Clarify uses heuristics to determine the [DataType](#). For post-training bias metrics, the data type returned by the model may not match what is in the dataset or SageMaker Clarify may not be able to transform it correctly.
- In the bias report, you should see a single value for categorical columns or an interval for continuous columns.
- For example, if a column has values 0.0 and 1.0 as floats, it will be treated as continuous even if there are too few unique values.

## Mismatch between analysis config and dataset/model input/output

- Check that the baseline format in the analysis config is the same as dataset format.
- If you receive the error message "Could not convert string to float.", check that the format is correctly specified. It could also indicate that the model predictions have a different format than the label column or it could indicate that the configuration for the label or probabilities is incorrect.
- If you receive the error message "Unable to locate the facet." or "Headers must contain label." or "Headers in config do not match with the number of columns in the dataset." or "Feature names not found.", check that the headers match the columns.

- If you receive the error message "Data must contain features.", check the content template for JSONLines and compare it with the dataset sample if available.

## Model returns 500 Internal Server Error or container falls back to per-record predictions due to model error

If you receive the error message "Fallback to per-record prediction because of model error.", this could indicate that model cannot handle the batch size, or be throttled, or just does not accept the input passed by the container due to serialization problems. You should review the CloudWatch logs for the SageMaker endpoint and look for error messages or tracebacks. For model throttling cases, it may help to use a different instance type or increasing the number of instances for the endpoint.

## Execution role is invalid

This indicates that the role provided is incorrect or missing required permissions. Check the role and its permissions that were used to configure the processing job and verify the permission and trust policy for the role.

## Failed to download data

This indicates that job inputs could not be downloaded for the job to start. Check the bucket name and permissions for the dataset and the configuration inputs.

## Could not connect to SageMaker

This indicates that the job could not reach SageMaker service endpoints. Check the network configuration settings for the processing job and verify VPC configuration.

# Model Explainability

Amazon SageMaker Clarify provides tools to help explain how machine learning (ML) models make predictions. These tools can help ML modelers and developers and other internal stakeholders understand model characteristics as a whole prior to deployment and to debug predictions provided by the model after it's deployed. Transparency about how ML models arrive at their predictions is also critical to consumers and regulators who need to trust the model predictions if they are going to accept the decisions based on them. SageMaker Clarify uses a model-agnostic feature attribution approach, which you can use to understand why a model made a prediction after training and to provide per-instance explanation during inference. The implementation includes a scalable and efficient implementation of [SHAP](#), based on the concept of a Shapley value from the field of cooperative game theory that assigns each feature an importance value for a particular prediction.

What is the function of an explanation in the machine learning context? An explanation can be thought of as the answer to a *Why question* that helps humans understand the cause of a prediction. In the context of an ML model, you might be interested in answering questions such as:

- "Why did the model predict a negative outcome such as a loan rejection for a given applicant?"
- "How does the model make predictions?"
- "Why did the model make an incorrect prediction?"
- "Which features have the largest influence on the behavior of the model?"

You can use explanations for auditing and meeting regulatory requirements, building trust in the model and supporting human decision-making, and debugging and improving model performance.

The need to satisfy the demands for human understanding about the nature and outcomes of ML inference is key to the sort of explanation needed. Research from philosophy and cognitive science disciplines has shown that people care especially about contrastive explanations, or explanations of why an event X happened instead of some other event Y that did not occur. Here, X could be an unexpected or surprising event that happened and Y corresponds to an expectation based on their existing mental model referred to as a *baseline*. Note that for the same event X, different people might seek different explanations depending on their point of view or mental model Y. In the context of explainable AI, you can think of X as the example being explained and Y as a baseline that is typically chosen to represent an uninformative or average example in the dataset. Sometimes, the baseline might be implicit as with an image with all pixels of the same color in the case of ML models for images.

- [SHAP Baselines for Explainability \(p. 1854\)](#)
- [Create Feature Attribute Baselines and Explainability Reports \(p. 1854\)](#)

## Feature Attributions that Use Shapley Values

SageMaker Clarify provides feature attributions based on the concept of [Shapley value](#). You can use Shapley values to determine the contribution that each feature made to model predictions. These attributions can be provided for specific predictions and at a global level for the model as a whole. For example, if you used an ML model for college admissions, the explanations could help determine whether the GPA or the SAT score was the feature most responsible for the model's predictions, and then you can determine how responsible each feature was for determining an admission decision about a particular student.

SageMaker Clarify has taken the concept of Shapley values from game theory and deployed it in a machine learning context. The Shapley value provides a way to quantify the contribution of each player to a game, and hence the means to distribute the total gain generated by a game to its players based on their contributions. In this machine learning context, SageMaker Clarify treats the prediction of the model on a given instance as the *game* and the features included in the model as the *players*. For a first approximation, you might be tempted to determine the marginal contribution or effect of each feature by quantifying the result of either *dropping* that feature from the model or *dropping* all other features from the model. However, this approach does not take into account that features included in a model are often not independent from each other. For example, if two features are highly correlated, dropping either one of the features might not alter the model prediction significantly.

To address these potential dependencies, the Shapley value requires that the outcome of each possible combination (or coalition) of features must be considered to determine the importance of each feature. Given  $d$  features, there are  $2^d$  such possible feature combinations, each corresponding to a potential model. To determine the attribution for a given feature  $f$ , consider the marginal contribution of including  $f$  in all feature combinations (and associated models) that do not contain  $f$ , and take the average. It can be shown that Shapley value is the unique way of assigning the contribution or importance of each feature that satisfies certain desirable properties. In particular, the sum of Shapley values of each feature corresponds to the difference between the predictions of the model and a dummy model with no features. However, even for reasonable values of  $d$ , say 50 features, it is computationally prohibitive and impractical to train  $2^d$  possible models. As a result, SageMaker Clarify needs to make use of various approximation techniques. For this purpose, SageMaker Clarify uses SHapley Additive exPlanations (SHAP), which incorporates such approximations and devised a scalable and efficient implementation of the Kernel SHAP algorithm through additional optimizations.

For additional information on Shapley values, see [A Unified Approach to Interpreting Model Predictions](#).

## SHAP Baselines for Explainability

As noted earlier, explanations are typically contrastive (that is, they account for deviations from a baseline). As a result, for the same model prediction, you can expect to get different explanations with respect to different baselines so your choice of a baseline is crucial. In an ML context, the baseline corresponds to a hypothetical instance that can be either *uninformative* or *informative*. During the computation of Shapley values, SageMaker Clarify generates several new instances between the baseline and the given instance, in which the absence of a feature is modeled by setting the feature value to that of the baseline and the presence of a feature is modeled by setting the feature value to that of the given instance. Thus, the absence of all features corresponds to the baseline and the presence of all features corresponds to the given instance.

How can you choose good baselines? Often it is desirable to select a baseline with very low information content. For example, you can construct an average instance from the training dataset by taking either the median or average for numerical features and the mode for categorical features. For the college admissions example, you might be interested in explaining why a particular applicant was accepted as compared to a baseline acceptances based on an average applicant.

Alternatively, you can choose to generate explanations with respect to informative baselines. For the college admissions scenario, you might want to explain why a particular applicant was rejected when compared with other applicants from similar demographic backgrounds. In this case, you can choose a baseline that represents the applicants of interest, namely those from a similar demographic background. Thus, you can use informative baselines to concentrate the analysis on the specific aspects of a particular model prediction. You can isolate the features for assessment by setting demographic attributes and other features that you can't act on to the same value as in the given instance.

## Create Feature Attribute Baselines and Explainability Reports

For an example notebook with instructions on how to run a SageMaker Clarify processing job in Studio that creates explanations for its predictions relative to a baseline, see [Explainability and bias detection with Amazon SageMaker Clarify](#).

If you need instructions on how to open a notebook in Amazon SageMaker Studio, see [Create or Open an Amazon SageMaker Studio Notebook \(p. 79\)](#). The following code examples are taken from the example notebook listed previously. This section discusses the code related to the use of Shapley values to provide reports that compare the relative contributions each feature made the predictions.

Use SHAPConfig to create the baseline. In this example, the mean\_abs is the mean of absolute SHAP values for all instances, specified as the baseline. You use DataConfig to configure the target variable, data input and output paths, and their formats.

```
shap_config = clarify.SHAPConfig(baseline=[test_features.iloc[0].values.tolist()],
                                 num_samples=15,
                                 agg_method='mean_abs')

explainability_output_path = 's3://{}//{}clarify-explainability'.format(bucket, prefix)
explainability_data_config = clarify.DataConfig(s3_data_input_path=train_uri,
                                               s3_output_path=explainability_output_path,
                                               label='Target',
                                               headers=training_data.columns.to_list(),
                                               dataset_type='text/csv')
```

Then run the explainability job.

```
clarify_processor.run_explainability(data_config=explainability_data_config,
```

```
model_config=model_config,  
explainability_config=shap_config)
```

View the results in Studio or download them from the `explainability_output_path` S3 bucket.

## Incremental Training in Amazon SageMaker

Over time, you might find that a model generates inference that are not as good as they were in the past. With incremental training, you can use the artifacts from an existing model and use an expanded dataset to train a new model. Incremental training saves both time and resources.

Use incremental training to:

- Train a new model using an expanded dataset that contains an underlying pattern that was not accounted for in the previous training and which resulted in poor model performance.
- Use the model artifacts or a portion of the model artifacts from a popular publicly available model in a training job. You don't need to train a new model from scratch.
- Resume a training job that was stopped.
- Train several variants of a model, either with different hyperparameter settings or using different datasets.

For more information about training jobs, see [Train a Model with Amazon SageMaker \(p. 8\)](#).

You can train incrementally using the SageMaker console or the [Amazon SageMaker Python SDK](#).

### Important

Only three built-in algorithms currently support incremental training: [Object Detection Algorithm \(p. 1479\)](#), [Image Classification Algorithm \(p. 1399\)](#), and [Semantic Segmentation Algorithm \(p. 1502\)](#).

### Topics

- [Perform Incremental Training \(Console\) \(p. 1855\)](#)
- [Perform Incremental Training \(API\) \(p. 1857\)](#)

## Perform Incremental Training (Console)

To complete this procedure, you need:

- The Amazon Simple Storage Service (Amazon S3) bucket URI where you've stored the training data.
- The S3 bucket URI where you want to store the output of the job.
- The Amazon Elastic Container Registry path where the training code is stored. For more information, see [Docker Registry Paths and Example Code \(p. 725\)](#).
- The URL of the S3 bucket where you've stored the model artifacts that you want to use in incremental training. To find the URL for the model artifacts, see the details page of the training job used to create the model. To find the details page, in the SageMaker console, choose **Inference**, choose **Models**, and then choose the model.

To restart a stopped training job, use the URL to the model artifacts that are stored in the details page as you would with a model or a completed training job.

### To perform incremental training (console)

1. Open the Amazon SageMaker console at <https://console.amazonaws.cn/sagemaker/>.

2. In the navigation pane, choose **Training**, then choose **Training jobs**.
3. Choose **Create training job**.
4. Provide a name for the training job. The name must be unique within an Amazon Region in an Amazon account. The training job name must have 1 to 63 characters. Valid characters: a-z, A-Z, 0-9, and . : + = @ \_ % - (hyphen).
5. Choose the algorithm that you want to use. For information about algorithms, see [Use Amazon SageMaker Built-in Algorithms \(p. 718\)](#).
6. (Optional) For **Resource configuration**, either leave the default values or increase the resource consumption to reduce computation time.
  - a. (Optional) For **Instance type**, choose the ML compute instance type that you want to use. In most cases, **ml.m4.xlarge** is sufficient.
  - b. For **Instance count**, use the default, 1.
  - c. (Optional) For **Additional volume per instance (GB)**, choose the size of the ML storage volume that you want to provision. In most cases, you can use the default, 1. If you are using a large dataset, use a larger size.
7. Provide information about the input data for the training dataset.
  - a. For **Channel name**, either leave the default (**train**) or enter a more meaningful name for the training dataset, such as **expanded-training-dataset**.
  - b. For **InputMode**, choose **File**. For incremental training, you need to use file input mode.
  - c. For **S3 data distribution type**, choose **FullyReplicated**. This causes each ML compute instance to use a full replicate of the expanded dataset when training incrementally.
  - d. If the expanded dataset is uncompressed, set the **Compression type** to **None**. If the expanded dataset is compressed using Gzip, set it to **Gzip**.
  - e. (Optional) If you are using File input mode, leave **Content type** empty. For Pipe input mode, specify the appropriate MIME type. **Content type** is the multipurpose internet mail extension (MIME) type of the data.
  - f. For **Record wrapper**, if the dataset is saved in RecordIO format, choose **RecordIO**. If your dataset is not saved as a RecordIO formatted file, choose **None**.
  - g. For **S3 data type**, if the dataset is stored as a single file, choose **S3Prefix**. If the dataset is stored as several files in a folder, choose **Manifest**.
  - h. For **S3 location**, provide the URL to the path where you stored the expanded dataset.
  - i. Choose **Done**.
8. To use model artifacts in a training job, you need to add a new channel and provide the needed information about the model artifacts.
  - a. For **Input data configuration**, choose **Add channel**.
  - b. For **Channel name**, enter **model1** to identify this channel as the source of the model artifacts.
  - c. For **InputMode**, choose **File**. Model artifacts are stored as files.
  - d. For **S3 data distribution type**, choose **FullyReplicated**. This indicates that each ML compute instance should use all of the model artifacts for training.
  - e. For **Compression type**, choose **None** because we are using a model for the channel.
  - f. Leave **Content type** empty. Content type is the multipurpose internet mail extension (MIME) type of the data. For model artifacts, we leave it empty.
  - g. Set **Record wrapper** to **None** because model artifacts are not stored in RecordIO format.
  - h. For **S3 data type**, if you are using a built-in algorithm or an algorithm that stores the model as a single file, choose **S3Prefix**. If you are using an algorithm that stores the model as several files, choose **Manifest**.
  - i. For **S3 location**, provide the URL to the path where you stored the model artifacts. Typically, the model is stored with the name **model1.tar.gz**. To find the URL for the model artifacts, in

- the navigation pane, choose **Inference**, then choose **Models**. From the list of models, choose a model to display its details page. The URL for the model artifacts is listed under **Primary container**.
- j. Choose **Done**.
  9. For **Output data configuration**, provide the following information:
    - a. For **S3 location**, type the path to the S3 bucket where you want to store the output data.
    - b. (Optional) For **Encryption key**, you can add your Amazon Key Management Service (Amazon KMS) encryption key to encrypt the output data at rest. Provide the key ID or its Amazon Resource Number (ARN). For more information, see [KMS-Managed Encryption Keys](#).
  10. (Optional) For **Tags**, add one or more tags to the training job. A **tag** is metadata that you can define and assign to Amazon resources. In this case, you can use tags to help you manage your training jobs. A tag consists of a key and a value, which you define. For example, you might want to create a tag with **Project** as a key and a value referring to a project that is related to the training job, such as **Home value forecasts**.
  11. Choose **Create training job**. SageMaker creates and runs training job.

After the training job has completed, the newly trained model artifacts are stored under the **S3 output path** that you provided in the **Output data configuration** field. To deploy the model to get predictions, see [Step 5: Deploy the Model to Amazon EC2 \(p. 63\)](#).

## Perform Incremental Training (API)

This example shows how to use SageMaker APIs to train a model using the SageMaker image classification algorithm and the [Caltech 256 Image Dataset](#), then train a new model using the first one. It uses Amazon S3 for input and output sources. Please see the [incremental training sample notebook](#) for more details on using incremental training.

### Note

In this example we used the original datasets in the incremental training, however you can use different datasets, such as ones that contain newly added samples. Upload the new datasets to S3 and make adjustments to the `data_channels` variable used to train the new model.

Get an Amazon Identity and Access Management (IAM) role that grants required permissions and initialize environment variables:

```
import sagemaker
from sagemaker import get_execution_role

role = get_execution_role()
print(role)

sess = sagemaker.Session()

bucket=sess.default_bucket()
print(bucket)
prefix = 'ic-incr-training'
```

Get the training image for the image classification algorithm:

```
from sagemaker.amazon.amazon_estimator import get_image_uri

training_image = get_image_uri(sess.boto_region_name, 'image-classification',
    repo_version="latest")
#Display the training image
print (training_image)
```

Download the training and validation datasets, then upload them to Amazon Simple Storage Service (Amazon S3):

```

import os
import urllib.request
import boto3

# Define a download function
def download(url):
    filename = url.split('/')[-1]
    if not os.path.exists(filename):
        urllib.request.urlretrieve(url, filename)

# Download the caltech-256 training and validation datasets
download('http://data.mxnet.io/data/caltech-256/caltech-256-60-train.rec')
download('http://data.mxnet.io/data/caltech-256/caltech-256-60-val.rec')

# Create four channels: train, validation, train_lst, and validation_lst
s3train = 's3://{}//{}//train/'.format(bucket, prefix)
s3validation = 's3://{}//{}//validation/'.format(bucket, prefix)

# Upload the first files to the train and validation channels
!aws s3 cp caltech-256-60-train.rec $s3train --quiet
!aws s3 cp caltech-256-60-val.rec $s3validation --quiet

```

Define the training hyperparameters:

```

# Define hyperparameters for the estimator
hyperparams = { "num_layers": "18",
                "resize": "32",
                "num_training_samples": "50000",
                "num_classes": "10",
                "image_shape": "3,28,28",
                "mini_batch_size": "128",
                "epochs": "3",
                "learning_rate": "0.1",
                "lr_scheduler_step": "2,3",
                "lr_scheduler_factor": "0.1",
                "augmentation_type": "crop_color",
                "optimizer": "sgd",
                "momentum": "0.9",
                "weight_decay": "0.0001",
                "beta_1": "0.9",
                "beta_2": "0.999",
                "gamma": "0.9",
                "eps": "1e-8",
                "top_k": "5",
                "checkpoint_frequency": "1",
                "use_pretrained_model": "0",
                "model_prefix": " " }

```

Create an estimator object and train the first model using the training and validation datasets:

```

# Fit the base estimator
s3_output_location = 's3://{}//{}//output'.format(bucket, prefix)
ic = sagemaker.estimator.Estimator(training_image,
                                     role,
                                     instance_count=1,
                                     instance_type='ml.p2.xlarge',
                                     volume_size=50,
                                     max_run=360000,
                                     input_mode='File',

```

```
        output_path=s3_output_location,
        sagemaker_session=sess,
        hyperparameters=hyperparams)

train_data = sagemaker.inputs.TrainingInput(s3train, distribution='FullyReplicated',
                                             content_type='application/x-recordio',
                                             s3_data_type='S3Prefix')
validation_data = sagemaker.inputs.TrainingInput(s3validation,
                                                 distribution='FullyReplicated',
                                                 content_type='application/x-recordio',
                                                 s3_data_type='S3Prefix')

data_channels = {'train': train_data, 'validation': validation_data}

ic.fit(inputs=data_channels, logs=True)
```

To use the model to incrementally train another model, create a new estimator object and use the model artifacts (`ic.model_data`, in this example) for the `model_uri` input argument:

```
# Given the base estimator, create a new one for incremental training
incr_ic = sagemaker.estimator.Estimator(training_image,
                                         role,
                                         instance_count=1,
                                         instance_type='ml.p2.xlarge',
                                         volume_size=50,
                                         max_run=360000,
                                         input_mode='File',
                                         output_path=s3_output_location,
                                         sagemaker_session=sess,
                                         hyperparameters=hyperparams,
                                         model_uri=ic.model_data) # This parameter will
                                         ingest the previous job's model as a new channel
incr_ic.fit(inputs=data_channels, logs=True)
```

After the training job has completed, the newly trained model artifacts are stored under the `S3_output_path` that you provided in `Output_path`. To deploy the model to get predictions, see [Step 5: Deploy the Model to Amazon EC2 \(p. 63\)](#).

## Managed Spot Training in Amazon SageMaker

Amazon SageMaker makes it easy to train machine learning models using managed Amazon EC2 Spot instances. Managed spot training can optimize the cost of training models up to 90% over on-demand instances. SageMaker manages the Spot interruptions on your behalf.

Managed Spot Training uses Amazon EC2 Spot instance to run training jobs instead of on-demand instances. You can specify which training jobs use spot instances and a stopping condition that specifies how long SageMaker waits for a job to run using Amazon EC2 Spot instances. Metrics and logs generated during training runs are available in CloudWatch.

Amazon SageMaker automatic model tuning, also known as hyperparameter tuning, can use managed spot training. For more information on automatic model training, see [Perform Automatic Model Tuning with SageMaker \(p. 1745\)](#).

Spot instances can be interrupted, causing jobs to take longer to start or finish. You can configure your managed spot training job to use checkpoints. SageMaker copies checkpoint data from a local path to Amazon S3. When the job is restarted, SageMaker copies the data from Amazon S3 back into the local path. The training job can then resume from the last checkpoint instead of restarting. For more information about checkpointing, see [Use Checkpoints in Amazon SageMaker \(p. 1860\)](#).

**Note**

Unless your training job will complete quickly, we recommend you use checkpointing with managed spot training. SageMaker built-in algorithms and marketplace algorithms that do not checkpoint are currently limited to a `MaxWaitTimeInSeconds` of 3600 seconds (60 minutes).

**Topics**

- [Using Managed Spot Training \(p. 1860\)](#)
- [Managed Spot Training Lifecycle \(p. 1860\)](#)

## Using Managed Spot Training

To use managed spot training, create a training job. Set `EnableManagedSpotTraining` to `True` and specify the `MaxWaitTimeInSeconds`. `MaxWaitTimeInSeconds` must be larger than `MaxRuntimeInSeconds`. For more information about creating a training job, see [DescribeTrainingJob](#).

You can calculate the savings from using managed spot training using the formula  $(1 - (\text{BillableTimeInSeconds} / \text{TrainingTimeInSeconds})) * 100$ . For example, if `BillableTimeInSeconds` is 100 and `TrainingTimeInSeconds` is 500, the savings is 80%.

## Managed Spot Training Lifecycle

You can monitor a training job using `TrainingJobStatus` and `SecondaryStatus` returned by [DescribeTrainingJob](#). The list below shows how `TrainingJobStatus` and `SecondaryStatus` values change depending on the training scenario:

- **Spot instances acquired with no interruption during training**
  1. `InProgress`: Starting → Downloading → Training → Uploading
- **Spot instances interrupted once. Later, enough spot instances were acquired to finish the training job.**
  1. `InProgress`: Starting → Downloading → Training → Interrupted → Starting → Downloading → Training → Uploading
- **Spot instances interrupted twice and `MaxWaitTimeInSeconds` exceeded.**
  1. `InProgress`: Starting → Downloading → Training → Interrupted → Starting → Downloading → Training → Interrupted → Downloading → Training
  2. `Stopping`: Stopping
  3. `Stopped`: `MaxWaitTimeExceeded`
- **Spot instances were never launched.**
  1. `InProgress`: Starting
  2. `Stopping`: Stopping
  3. `Stopped`: `MaxWaitTimeExceeded`

## Use Checkpoints in Amazon SageMaker

Use checkpoints in Amazon SageMaker to save the state of machine learning (ML) models during training. Checkpoints are snapshots of the model and can be configured by the callback functions of ML frameworks. You can use the saved checkpoints to restart a training job from the last saved checkpoint.

The SageMaker training mechanism uses training containers on Amazon EC2 instances, and the checkpoint files are saved under a local directory of the containers. SageMaker provides functionality to copy the checkpoints from the local path to Amazon S3. Using checkpoints, you can do the following:

- Save your model snapshots under training due to an unexpected interruption to the training job or instance.
- Resume training the model in the future from a checkpoint.
- Analyze the model at intermediate stages of training.
- Use checkpoints with SageMaker managed spot training to save on training costs.

If you are using checkpoints with SageMaker managed spot training, SageMaker manages checkpointing your model training on a spot instance and resuming the training job on the next spot instance. With SageMaker managed spot training, you can significantly reduce the billable time for training ML models. For more information, see [Managed Spot Training in Amazon SageMaker \(p. 1859\)](#).

- [Considerations for Checkpointing \(p. 1864\)](#)

## Checkpoints for Frameworks and Algorithms in SageMaker

Use checkpoints to save snapshots of ML models built on your preferred frameworks within SageMaker.

### SageMaker frameworks and algorithms that support checkpointing

SageMaker supports checkpointing for Deep Learning Containers and a subset of built-in algorithms without requiring training script changes. SageMaker saves the checkpoints to the default local path '/opt/ml/checkpoints' and copies them to Amazon S3.

- Deep Learning Containers: [TensorFlow](#), [PyTorch](#), [MXNet](#), and [HuggingFace](#)

#### Note

If you are using the HuggingFace framework estimator, you need to specify a checkpoint output path through hyperparameters. For more information, see [Run training on Amazon SageMaker](#) in the *HuggingFace documentation*.

- Built-in algorithms: [Image Classification](#), [Object Detection](#), [Semantic Segmentation](#), and [XGBoost \(0.90-1 or later\)](#)

#### Note

If you are using the XGBoost algorithm in framework mode (script mode), you need to bring an XGBoost training script with checkpointing that's manually configured. For more information about the XGBoost training methods to save model snapshots, see [Training XGBoost](#) in the *XGBoost Python SDK documentation*.

If a pre-built algorithm that does not support checkpointing is used in a managed spot training job, SageMaker does not allow a maximum wait time greater than an hour for the job in order to limit wasted training time from interrupts.

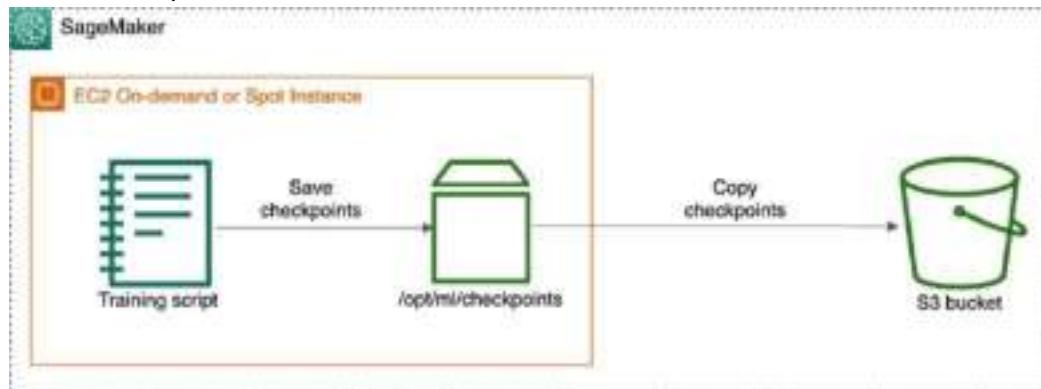

### For custom training containers and other frameworks

If you are using your own training containers, training scripts, or other frameworks not listed in the previous section, you must properly set up your training script using callbacks or training APIs to save

checkpoints to the local path ('/opt/ml/checkpoints') and load from the local path in your training script. SageMaker estimators can sync up with the local path and save the checkpoints to Amazon S3.

## Enable Checkpointing

After you enable checkpointing, SageMaker saves checkpoints to Amazon S3 and syncs your training job with the checkpoint S3 bucket.

The following example shows how to configure checkpoint paths when you construct a SageMaker estimator. To enable checkpointing, add the `checkpoint_s3_uri` and `checkpoint_local_path` parameters to your estimator.

The following example template shows how to create a generic SageMaker estimator and enable checkpointing. You can use this template for the supported algorithms by specifying the `image_uri` parameter. To find Docker image URIs for algorithms with checkpointing supported by SageMaker, see [Docker Registry Paths and Example Code \(p. 725\)](#). You can also replace `estimator` and `Estimator` with other SageMaker frameworks' estimator parent classes and estimator classes, such as [TensorFlow](#), [PyTorch](#), [MXNet](#), [HuggingFace](#) and [XGBoost](#).

```

import sagemaker
from sagemaker.estimator import Estimator

bucket=sagemaker.Session().default_bucket()
base_job_name="sagemaker-checkpoint-test"
checkpoint_in_bucket="checkpoints"

# The S3 URI to store the checkpoints
checkpoint_s3_bucket="s3://{}//{}//{}".format(bucket, base_job_name, checkpoint_in_bucket)

# The local path where the model will save its checkpoints in the training container
checkpoint_local_path="/opt/ml/checkpoints"

estimator = Estimator(
    ...
    image_uri="

```

The following two parameters specify paths for checkpointing:

- `checkpoint_local_path` – Specify the local path where the model saves the checkpoints periodically in a training container. The default path is set to '/opt/ml/checkpoints'. If you are

using other frameworks or bringing your own training container, ensure that your training script's checkpoint configuration specifies the path to '/opt/ml/checkpoints'.

**Note**

We recommend specifying the local paths as '/opt/ml/checkpoints' to be consistent with the default SageMaker checkpoint settings. If you prefer to specify your own local path, make sure you match the checkpoint saving path in your training script and the `checkpoint_local_path` parameter of the SageMaker estimators.

- `checkpoint_s3_uri` – The URI to an S3 bucket where the checkpoints are stored in real time.

To find a complete list of SageMaker estimator parameters, see the [Estimator API](#) in the [Amazon SageMaker Python SDK documentation](#).

## Browse Checkpoint Files

Locate checkpoint files using the SageMaker Python SDK and the Amazon S3 console.

### To find the checkpoint files programmatically

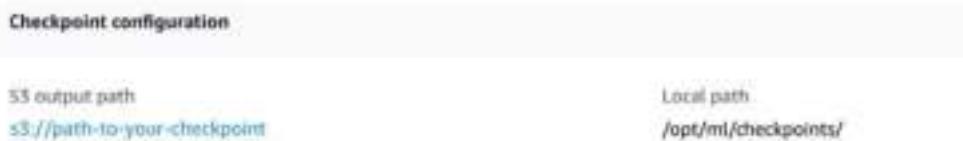

To retrieve the S3 bucket URI where the checkpoints are saved, check the following estimator attribute:

```
estimator.checkpoint_s3_uri
```

This returns the Amazon S3 output path for checkpoints configured while requesting the `CreateTrainingJob` request. To find the saved checkpoint files using the Amazon S3 console, use the following procedure.

### To find the checkpoint files from the Amazon S3 console

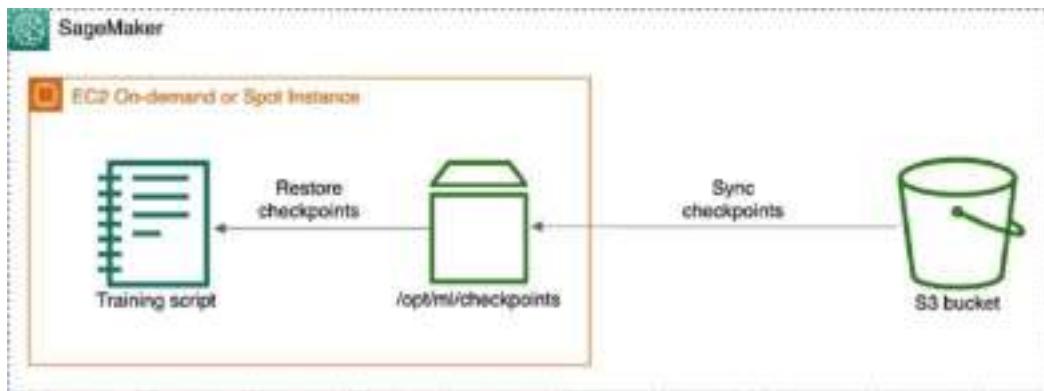

1. Sign in to the Amazon Web Services Management Console and open the SageMaker console at <https://console.amazonaws.cn/sagemaker/>.
2. In the left navigation pane, choose **Training jobs**.
3. Choose the link to the training job with checkpointing enabled to open **Job settings**.
4. On the **Job settings** page of the training job, locate the **Checkpoint configuration** section.

5. Use the link to the S3 bucket to access the checkpoint files.

## Resume Training From a Checkpoint

To resume a training job from a checkpoint, run a new estimator with the same `checkpoint_s3_uri` that you created in the [Enable Checkpointing \(p. 1862\)](#) section. Once the training has resumed, the checkpoints from this S3 bucket are restored to `checkpoint_local_path` in each instance of the new training job. Ensure that the S3 bucket is in the same Region as that of the current SageMaker session.

## Considerations for Checkpointing

Consider the following when using checkpoints in SageMaker.

- To avoid overwrites in distributed training with multiple instances, you must manually configure the checkpoint file names and paths in your training script. The high-level SageMaker checkpoint configuration specifies a single Amazon S3 location without additional suffixes or prefixes to tag checkpoints from multiple instances.
- The SageMaker Python SDK does not support high-level configuration for checkpointing frequency. To control the checkpointing frequency, modify your training script using the framework's model save functions or checkpoint callbacks.
- If you use SageMaker checkpoints with SageMaker Debugger and SageMaker distributed and are facing issues, see the following pages for troubleshooting and considerations.
  - [Considerations for Amazon SageMaker Debugger \(p. 1741\)](#)
  - [Data Parallel Troubleshooting \(p. 1794\)](#)
  - [Model Parallel Troubleshooting \(p. 1817\)](#)

## Provide Dataset Metadata to Training Jobs with an Augmented Manifest File

To include metadata with your dataset in a training job, use an augmented manifest file. When using an augmented manifest file, your dataset must be stored in Amazon Simple Storage Service (Amazon S3) and you must configure your training job to use dataset stored there. You specify the location and format of this dataset for one or more [Channel](#). Augmented manifests can only support Pipe input mode. See the section, [InputMode](#) in [Channel](#) to learn more about pipe input mode.

When specifying a channel's parameters, you specify a path to the file, called a `S3Uri`. Amazon SageMaker interprets this URI based on the specified `S3DataType` in `S3DataSource`. The `AugmentedManifestFile` option defines a manifest format that includes metadata with the input data. Using an augmented manifest file is an alternative to preprocessing when you have labeled data. For training jobs using labeled data, you typically need to preprocess the dataset to combine input data with metadata before training. If your training dataset is large, preprocessing can be time consuming and expensive.

## Augmented Manifest File Format

An augmented manifest file must be formatted in [JSON Lines](#) format. In JSON Lines format, each line in the file is a complete JSON object followed by a newline separator.

During training, SageMaker parses each JSON line and sends some or all of its attributes on to the training algorithm. You specify which attribute contents to pass and the order in which to pass them with the `AttributeNames` parameter of the [CreateTrainingJob](#) API. The `AttributeNames` parameter is an ordered list of attribute names that SageMaker looks for in the JSON object to use as training input.

For example, if you list `["line", "book"]` for `AttributeNames`, the input data must include the attribute names of `line` and `book` in the specified order. For this example, the following augmented manifest file content is valid:

```
{"author": "Herman Melville", "line": "Call me Ishmael", "book": "Moby Dick"}  
{"line": "It was love at first sight.", "author": "Joseph Heller", "book": "Catch-22"}
```

SageMaker ignores unlisted attribute names even if they precede, follow, or are in between listed attributes.

When using augmented manifest files, observe the following guidelines:

- The order of the attributes listed in the `AttributeNames` parameter determines the order of the attributes passed to the algorithm in the training job.
- The listed `AttributeNames` can be a subset of all of the attributes in the JSON line. SageMaker ignores unlisted attributes in the file.
- You can specify any type of data allowed by the JSON format in `AttributeNames`, including text, numerical, data arrays, or objects.
- To include an S3 URI as an attribute name, add the suffix `-ref` to it.

If an attribute name contains the suffix `-ref`, the attribute's value must be an S3 URI to a data file that is accessible to the training job. For example, if `AttributeNames` contains `["image-ref", "is-a-cat"]`, a valid augmented manifest file might contain these lines:

```
{"image-ref": "s3://mybucket/sample01/image1.jpg", "is-a-cat": 1}  
{"image-ref": "s3://mybucket/sample02/image2.jpg", "is-a-cat": 0}
```

For the first line of this manifest, SageMaker retrieves the contents of the S3 object `s3://mybucket/foo/image1.jpg` and streams it to the algorithm for training. The second line is the string representation of the `is-a-cat` attribute `"1"`, which is followed by the contents of the second line.

## Stream Augmented Manifest File Data

Augmented manifest format enables you to do training in Pipe mode using files without needing to create RecordIO files. You need to specify both train and validation channels as values for the `InputDataConfig` parameter of the [CreateTrainingJob](#) request. Augmented manifest files are supported only for channels using Pipe input mode. For each channel, the data is extracted from its augmented manifest file and streamed (in order) to the algorithm through the channel's named pipe. Pipe mode uses the first in first out (FIFO) method, so records are processed in the order in which they are queued. For information about Pipe input mode, see [Input Mode](#).

Attribute names with a `"-ref"` suffix point to preformatted binary data. In some cases, the algorithm knows how to parse the data. In other cases, you might need to wrap the data so that records are delimited for the algorithm. If the algorithm is compatible with [RecordIO-formatted data](#), specifying `RecordIO` for `RecordWrapperType` solves this issue. If the algorithm is not compatible with `RecordIO` format, specify `None` for `RecordWrapperType` and make sure that your data is parsed correctly for your algorithm.

Using the `["image-ref", "is-a-cat"]` example, if you use `RecordIO` wrapping, the following stream of data is sent to the queue:

```
recordio_formatted(s3://mybucket/foo/  
image1.jpg)recordio_formatted("1")recordio_formatted(s3://mybucket/bar/  
image2.jpg)recordio_formatted("0")
```

Images that are not wrapped with RecordIO format, are streamed with the corresponding `is-a-cat` attribute value as one record. This can cause a problem because the algorithm might not delimit the images and attributes correctly. For more information about using augmented manifest files for image classification, see [Train with Augmented Manifest Image Format](#).

With augmented manifest files and Pipe mode in general, size limits of the EBS volume do not apply. This includes settings that otherwise must be within the EBS volume size limit such as `S3DataDistributionType`. For more information about Pipe mode and how to use it, see [Using Your Own Training Algorithms - Input Data Configuration](#).

## Use an Augmented Manifest File (Console)

To complete this procedure, you need:

- The URL of the S3 bucket where you've stored the augmented manifest file.
- To store the data that is listed in the augmented manifest file in an S3 bucket.
- The URL of the S3 bucket where you want to store the output of the job.

### To use an augmented manifest file in a training job (console)

1. Open the Amazon SageMaker console at <https://console.amazonaws.cn/sagemaker/>.
2. In the navigation pane, choose **Training**, then choose **Training jobs**.
3. Choose **Create training job**.
4. Provide a name for the training job. The name must be unique within an Amazon Region in an Amazon account. It can have 1 to 63 characters. Valid characters: a-z, A-Z, 0-9, and . : + = @ \_ % - (hyphen).
5. Choose the algorithm that you want to use. For information about supported built-in algorithms, see [Use Amazon SageMaker Built-in Algorithms \(p. 718\)](#). If you want to use a custom algorithm, make sure that it is compatible with Pipe mode.
6. (Optional) For **Resource configuration**, either accept the default values or, to reduce computation time, increase the resource consumption.
  - a. (Optional) For **Instance type**, choose the ML compute instance type that you want to use. In most cases, **ml.m4.xlarge** is sufficient.
  - b. For **Instance count**, use the default, 1.
  - c. (Optional) For **Additional volume per instance (GB)**, choose the size of the ML storage volume that you want to provision. In most cases, you can use the default, 1. If you are using a large dataset, use a larger size.
7. Provide information about the input data for the training dataset.
  - a. For **Channel name**, either accept the default (**train**) or enter a more meaningful name, such as **training-augmented-manifest-file**.
  - b. For **InputMode**, choose **Pipe**.
  - c. For **S3 data distribution type**, choose **FullyReplicated**. When training incrementally, fully replicating causes each ML compute instance to use a complete copy of the expanded dataset. For neural-based algorithms, such as [Neural Topic Model \(NTM\) Algorithm \(p. 1457\)](#), choose **ShardedByS3Key**.
  - d. If the data specified in the augmented manifest file is uncompressed, set the **Compression type** to **None**. If the data is compressed using gzip, set it to **Gzip**.

- e. (Optional) For **Content type**, specify the appropriate MIME type. Content type is the multipurpose internet mail extension (MIME) type of the data.
- f. For **Record wrapper**, if the dataset specified in the augmented manifest file is saved in RecordIO format, choose **RecordIO**. If your dataset is not saved as a RecordIO-formatted file, choose **None**.
- g. For **S3 data type**, choose **AugmentedManifestFile**.
- h. For **S3 location**, provide the path to the bucket where you stored the augmented manifest file.
- i. For **AugmentedManifestFile attribute names**, specify the name of an attribute that you want to use. The attribute name must be present within the augmented manifest file, and is case-sensitive.
- j. (Optional) To add more attribute names, choose **Add row** and specify another attribute name for each attribute.
- k. (Optional) To adjust the order of attribute names, choose the up or down buttons next to the names. When using an augmented manifest file, the order of the specified attribute names is important.
- l. Choose **Done**.
8. For **Output data configuration**, provide the following information:
  - a. For **S3 location**, type the path to the S3 bucket where you want to store the output data.
  - b. (Optional) You can use your Amazon Key Management Service (Amazon KMS) encryption key to encrypt the output data at rest. For **Encryption key**, provide the key ID or its Amazon Resource Number (ARN). For more information, see [KMS-Managed Encryption Keys](#).
9. (Optional) For **Tags**, add one or more tags to the training job. A **tag** is metadata that you can define and assign to Amazon resources. In this case, you can use tags to help you manage your training jobs. A tag consists of a key and a value, which you define. For example, you might want to create a tag with **Project** as a key and a value that refers to a project that is related to the training job, such as **Home value forecasts**.
10. Choose **Create training job**. SageMaker creates and runs the training job.

After the training job has finished, SageMaker stores the model artifacts in the bucket whose path you provided for **S3 output path** in the **Output data configuration** field. To deploy the model to get predictions, see [Step 5: Deploy the Model to Amazon EC2 \(p. 63\)](#).

## Use an Augmented Manifest File (API)

The following shows how to train a model with an augmented manifest file using the SageMaker high-level Python library:

```
# Create a model object set to using "Pipe" mode.
model = sagemaker.estimator.Estimator(training_image,
                                       role,
                                       instance_count=1,
                                       instance_type='ml.p3.2xlarge',
                                       volume_size = 50,
                                       max_run = 360000,
                                       input_mode = 'Pipe',
                                       output_path=s3_output_location,
                                       sagemaker_session=session)

# Create a train data channel with S3_data_type as 'AugmentedManifestFile' and attribute
# names.
train_data = sagemaker.session.s3_input(your_augmented_manifest_file,
                                         distribution='FullyReplicated',
                                         content_type='application/x-recordio',
                                         s3_data_type='AugmentedManifestFile',
```

```
attribute_names=[ 'source-ref' , 'annotations' ],
input_mode='Pipe',
record_wrapping='RecordIO')

data_channels = {'train': train_data}

# Train a model.
model.fit(inputs=data_channels, logs=True)
```

After the training job has finished, SageMaker stores the model artifacts in the bucket whose path you provided for **S3 output path** in the **Output data configuration** field. To deploy the model to get predictions, see [Step 5: Deploy the Model to Amazon EC2 \(p. 63\)](#).

## Monitor and Analyze Training Jobs Using Metrics

An Amazon SageMaker training job is an iterative process that teaches a model to make predictions by presenting examples from a training dataset. Typically, a training algorithm computes several metrics, such as training error and prediction accuracy. These metrics help diagnose whether the model is learning well and will generalize well for making predictions on unseen data. The training algorithm writes the values of these metrics to logs, which SageMaker monitors and sends to Amazon CloudWatch in real time. To analyze the performance of your training job, you can view graphs of these metrics in CloudWatch. When a training job has completed, you can also get a list of the metric values that it computes in its final iteration by calling the [DescribeTrainingJob](#) operation.

### Topics

- [Defining Training Metrics \(p. 1868\)](#)
- [Monitoring Training Job Metrics \( Console\) \(p. 1871\)](#)
- [Monitoring Training Job Metrics \(SageMaker Console\) \(p. 1871\)](#)
- [Example: Viewing a Training and Validation Curve \(p. 1873\)](#)

## Training Metrics Sample Notebooks

The following sample notebooks show how to view and plot training metrics:

- [An Introduction to the Amazon SageMaker ObjectToVec Model for Sequence-to-sequence Embedding \(object2vec\\_sentence\\_similarity.ipynb\)](#)
- [Regression with the Amazon SageMaker XGBoost Algorithm \(xgboost\\_abalone.ipynb\)](#)

For instructions how to create and access Jupyter notebook instances that you can use to run the examples in SageMaker, see [Example Notebooks \(p. 131\)](#). To see a list of all the SageMaker samples, after creating and opening a notebook instance, choose the **SageMaker Examples** tab. To access the example notebooks that show how to use training metrics, `object2vec_sentence_similarity.ipynb` and `xgboost_abalone.ipynb`, from the **Introduction to Amazon algorithms** section. To open a notebook, choose its **Use** tab, then choose **Create copy**.

## Defining Training Metrics

SageMaker automatically parses the logs for metrics that built-in algorithms emit and sends those metrics to CloudWatch. If you want SageMaker to parse logs from a custom algorithm and send metrics that the algorithm emits to CloudWatch, you have to specify the metrics that you want SageMaker to

send to CloudWatch when you configure the training job. You specify the name of the metrics that you want to send and the regular expressions that SageMaker uses to parse the logs that your algorithm emits to find those metrics.

You can specify the metrics that you want to track with the SageMaker console; the SageMaker Python SDK (<https://github.com/aws/sagemaker-python-sdk>), or the low-level SageMaker API.

### Topics

- [Defining Regular Expressions for Metrics \(p. 1869\)](#)
- [Defining Training Metrics \(Low-level SageMaker API\) \(p. 1869\)](#)
- [Defining Training Metrics \(SageMaker Python SDK\) \(p. 1870\)](#)
- [Define Training Metrics \(Console\) \(p. 1870\)](#)

## Defining Regular Expressions for Metrics

To find a metric, SageMaker searches the logs that your algorithm emits and finds logs that match the regular expression that you specify for that metric. If you are using your own algorithm, do the following:

- Make sure that the algorithm writes the metrics that you want to capture to logs
- Define a regular expression that accurately searches the logs to capture the values of the metrics that you want to send to CloudWatch metrics.

For example, suppose your algorithm emits metrics for training error and validation error by writing logs similar to the following to `stdout` or `stderr`:

```
Train_error=0.138318;  Valid_error = 0.324557;
```

If you want to monitor both of those metrics in CloudWatch, your `AlgorithmSpecification` would look like the following:

```
"AlgorithmSpecification": {  
    "TrainingImage": ContainerName,  
    "TrainingInputMode": "File",  
    "MetricDefinitions" : [  
        {  
            "Name": "train:error",  
            "Regex": "Train_error=(.*?);"  
        },  
        {  
            "Name": "validation:error",  
            "Regex": "Valid_error=(.*?);"  
        }  
    ]  
}
```

In the regex for the `train:error` metric defined above, the first part of the regex finds the exact text "Train\_error=", and the expression `(.*?)`; captures zero or more of any character until the first semicolon character. In this expression, the parenthesis tell the regex to capture what is inside them, . means any character, \* means zero or more, and ? means capture only until the first instance of the ; character.

## Defining Training Metrics (Low-level SageMaker API)

Define the metrics that you want to send to CloudWatch by specifying a list of metric names and regular expressions in the `MetricDefinitions` field of the `AlgorithmSpecification` input parameter

that you pass to the [CreateTrainingJob](#) operation. For example, if you want to monitor both the `train:error` and `validation:error` metrics in CloudWatch, your `AlgorithmSpecification` would look like the following:

```
"AlgorithmSpecification": {
    "TrainingImage": ContainerName,
    "TrainingInputMode": "File",
    "MetricDefinitions" : [
        {
            "Name": "train:error",
            "Regex": "Train_error=(.*?);"
        },
        {
            "Name": "validation:error",
            "Regex": "Valid_error=(.*?);"
        }
    ]
}
```

For more information about defining and running a training job by using the low-level SageMaker API, see [CreateTrainingJob](#).

## Defining Training Metrics (SageMaker Python SDK)

Define the metrics that you want to send to CloudWatch by specifying a list of metric names and regular expressions as the `metric_definitions` argument when you initialize an `Estimator` object. For example, if you want to monitor both the `train:error` and `validation:error` metrics in CloudWatch, your `Estimator` initialization would look like the following:

```
estimator =
    Estimator(image_name=ImageName,
              role='SageMakerRole',
              instance_count=1,
              instance_type='ml.c4.xlarge',
              k=10,
              sagemaker_session=sagemaker_session,
              metric_definitions=[
                  {'Name': 'train:error', 'Regex': 'Train_error=(.*?);'},
                  {'Name': 'validation:error', 'Regex': 'Valid_error=(.*?);'}
              ])

```

For more information about training by using [Amazon SageMaker Python SDK](#) estimators, see <https://github.com/aws/sagemaker-python-sdk#sagemaker-python-sdk-overview>.

## Define Training Metrics (Console)

You can define metrics for a custom algorithm in the console when you create a training job by providing the name and regular expression (regex) for **Metrics**.

For example, if you want to monitor both the `train:error` and `validation:error` metrics in CloudWatch, your metric definitions would look like the following:

```
[
    {
        "Name": "train:error",
        "Regex": "Train_error=(.*?);"
    },
    {
        "Name": "validation:error",
        "Regex": "Valid_error=(.*?);"
    }
]
```

```
{  
    "Name": "validation:error",  
    "Regex": "Valid_error=(.*?);"  
}  
]
```

## Monitoring Training Job Metrics ( Console)

You can monitor the metrics that a training job emits in real time in the CloudWatch console.

### To monitor training job metrics (CloudWatch console)

1. Open the CloudWatch console at <https://console.amazonaws.cn/cloudwatch>.
2. Choose **Metrics**, then choose [/aws/sagemaker/TrainingJobs](#).
3. Choose **TrainingJobName**.
4. On the **All metrics** tab, choose the names of the training metrics that you want to monitor.
5. On the **Graphed metrics** tab, configure the graph options. For more information about using CloudWatch graphs, see [Graph Metrics](#) in the *Amazon CloudWatch User Guide*.

## Monitoring Training Job Metrics (SageMaker Console)

You can monitor the metrics that a training job emits in real time by using the SageMaker console.

### To monitor training job metrics (SageMaker console)

1. Open the SageMaker console at <https://console.amazonaws.cn/sagemaker>.
2. Choose **Training jobs**, then choose the training job whose metrics you want to see.
3. Choose **TrainingJobName**.
4. In the **Monitor** section, you can review the graphs of instance utilization and algorithm metrics.

## Example: Viewing a Training and Validation Curve

Typically, you split the data that you train your model on into training and validation datasets. You use the training set to train the model parameters that are used to make predictions on the training dataset. Then you test how well the model makes predictions by calculating predictions for the validation set. To analyze the performance of a training job, you commonly plot a training curve against a validation curve.

Viewing a graph that shows the accuracy for both the training and validation sets over time can help you to improve the performance of your model. For example, if training accuracy continues to increase over time, but, at some point, validation accuracy starts to decrease, you are likely overfitting your model. To address this, you can make adjustments to your model, such as increasing [regularization](#).

For this example, you can use the [Image-classification-full-training](#) example that is in the [Example notebooks](#) section of your SageMaker notebook instance. If you don't have a SageMaker notebook instance, create one by following the instructions at [Step 1: Create an Amazon SageMaker Notebook Instance \(p. 53\)](#). If you prefer, you can follow along with the [End-to-End Multiclass Image Classification Example](#) in the example notebook on GitHub. You also need an Amazon S3 bucket to store the training data and for the model output.

### To view training and validation error curves

1. Open the SageMaker console at <https://console.amazonaws.cn/sagemaker>.
2. Choose **Notebooks**, and then choose **Notebook instances**.
3. Choose the notebook instance that you want to use, and then choose **Open**.
4. On the dashboard for your notebook instance, choose **SageMaker Examples**.
5. Expand the **Introduction to Amazon Algorithms** section, and then choose **Use** next to **Image-classification-fulltraining.ipynb**.
6. Choose **Create copy**. SageMaker creates an editable copy of the **Image-classification-fulltraining.ipynb** notebook in your notebook instance.
7. Run all of the cells in the notebook up to the **Inference** section. You don't need to deploy an endpoint or get inference for this example.
8. After the training job starts, open the CloudWatch console at <https://console.amazonaws.cn/cloudwatch>.
9. Choose **Metrics**, then choose [/aws/sagemaker/TrainingJobs](#).
10. Choose **TrainingJobName**.
11. On the **All metrics** tab, choose the **train:accuracy** and **validation:accuracy** metrics for the training job that you created in the notebook.
12. On the graph, choose an area that the metric's values to zoom in. You should see something like the following:

## Untitled graph

# Deploy Models for Inference

After you build and train your models, you can deploy them to get predictions in one of two ways:

- To set up a persistent endpoint to get predictions from your models, use Amazon SageMaker hosting services. For an overview on deploying a single model or multiple models with SageMaker hosting services, see [Deploy a Model on SageMaker Hosting Services \(p. 10\)](#).

For an example of how to deploy a model to the SageMaker hosting service, see [Deploy the Model to SageMaker Hosting Services \(p. 63\)](#).

Or, if you prefer, watch the following video tutorial:

[Deploy Your ML Models to Production at Scale with Amazon SageMaker](#)

- To get predictions for an entire dataset, use SageMaker batch transform. For an overview on deploying a model with SageMaker batch transform, see [Get Inferences for an Entire Dataset with Batch Transform \(p. 13\)](#).

For an example of how to deploy a model with batch transform, see [\(Optional\) Make Prediction with Batch Transform \(p. 64\)](#).

Or, if you prefer, watch the following video tutorial:

[Deploy Your ML Models to Production at Scale with Amazon SageMaker](#)

## Prerequisites

These topics assume that you have built and trained one or more machine learning models and are ready to deploy them. If you are new to SageMaker and have not completed these prerequisite tasks, work through the steps in the [Get Started with Amazon SageMaker \(p. 34\)](#) tutorial to familiarize yourself with an example of how SageMaker manages the data science process and how it handles model deployment. For more information about training a model, see [Train Models \(p. 713\)](#).

## What do you want to do?

SageMaker provides features to manage resources and optimize inference performance when deploying machine learning models. For guidance on using inference pipelines, compiling and deploying models with Neo, Elastic Inference, and automatic model scaling, see the following topics.

- To manage data processing and real-time predictions or to process batch transforms in a pipeline, see [Deploy an Inference Pipeline \(p. 1917\)](#).
- If you want to deploy a model on inf1 instances, see [Compile and Deploy Models with Neo \(p. 2021\)](#).
- To train TensorFlow, Apache MXNet, PyTorch, ONNX, and XGBoost models once and optimize them to deploy on ARM, Intel, and Nvidia processors, see [Compile and Deploy Models with Neo \(p. 2021\)](#).
- To preprocess entire datasets quickly or to get inferences from a trained model for large datasets when you don't need a persistent endpoint, see [Use Batch Transform \(p. 1888\)](#).
- To speed up the throughput and decrease the latency of getting real-time inferences from your deep learning models that are deployed as SageMaker hosted models using a GPU instance for your endpoint, see [Use Amazon SageMaker Elastic Inference \(EI\) \(p. 1876\)](#).

- To dynamically adjust the number of instances provisioned in response to changes in your workload, see [Automatically Scale Amazon SageMaker Models \(p. 1931\)](#).
- To create an endpoint that can host multiple models using a shared serving container, see [Host Multiple Models with Multi-Model Endpoints \(p. 1895\)](#).
- To test multiple models in production, see [Test models in production \(p. 1947\)](#).

## Manage Model Deployments

For guidance on managing model deployments, including monitoring, troubleshooting, and best practices, and for information on storage associated with inference hosting instances:

- For tools that can be used to monitor model deployments, see [Monitor Amazon SageMaker \(p. 2523\)](#).
- For troubleshooting model deployments, see [Troubleshoot Amazon SageMaker Model Deployments \(p. 1955\)](#).
- For model deployment best practices, see [Deployment Best Practices \(p. 1956\)](#).
- For information about the size of storage volumes provided for different sizes of hosting instances, see [Host Instance Storage Volumes \(p. 1946\)](#).

## Deploy Your Own Inference Code

For developers that need more advanced guidance on how to run your own inference code:

- To run your own inference code hosting services, see [Use Your Own Inference Code with Hosting Services \(p. 2167\)](#).
- To run your own inference code for batch transforms, see [Use Your Own Inference Code with Batch Transform \(p. 2172\)](#).

## Guide to SageMaker

[What Is Amazon SageMaker? \(p. 1\)](#)

## Use Amazon SageMaker Elastic Inference (EI)

This feature is not available in the China Regions.

By using Amazon Elastic Inference (EI), you can speed up the throughput and decrease the latency of getting real-time inferences from your deep learning models that are deployed as [Amazon SageMaker hosted models](#), but at a fraction of the cost of using a GPU instance for your endpoint. EI allows you to add inference acceleration to a hosted endpoint for a fraction of the cost of using a full GPU instance. Add an EI accelerator in one of the available sizes to a deployable model in addition to a CPU instance type, and then add that model as a production variant to an endpoint configuration that you use to deploy a hosted endpoint. You can also add an EI accelerator to a SageMaker [notebook instance](#) so that you can test and evaluate inference performance when you are building your models.

Elastic Inference is supported in EI-enabled versions of TensorFlow, Apache MXNet, and PyTorch. To use any other deep learning framework, export your model by using ONNX, and then import your model into

MXNet. You can then use your model with EI as an MXNet model. For information about importing an ONNX model into MXNet, see [Importing an ONNX model into MXNet](#).

#### Topics

- [How EI Works \(p. 1877\)](#)
- [Choose an EI Accelerator Type \(p. 1877\)](#)
- [Use EI in a SageMaker Notebook Instance \(p. 1878\)](#)
- [Use EI on a Hosted Endpoint \(p. 1878\)](#)
- [Frameworks that Support EI \(p. 1878\)](#)
- [Use EI with SageMaker Built-in Algorithms \(p. 1879\)](#)
- [EI Sample Notebooks \(p. 1879\)](#)
- [Set Up to Use EI \(p. 1879\)](#)
- [Attach EI to a Notebook Instance \(p. 1882\)](#)
- [Use EI on Amazon SageMaker Hosted Endpoints \(p. 1884\)](#)

## How EI Works

Amazon Elastic Inference accelerators are network attached devices that work along with SageMaker instances in your endpoint to accelerate your inference calls. Elastic Inference accelerates inference by allowing you to attach fractional GPUs to any SageMaker instance. You can select the client instance to run your application and attach an Elastic Inference accelerator to use the right amount of GPU acceleration for your inference needs. Elastic Inference helps you lower your cost when not fully utilizing your GPU instance for inference. We recommend trying Elastic Inference with your model using different CPU instances and accelerator sizes.

The following EI accelerator types are available. You can configure your endpoints or notebook instances with any EI accelerator type.

In the table, the throughput in teraflops (TFLOPS) is listed for both single-precision floating-point (F32) and half-precision floating-point (F16) operations. The memory in GB is also listed.

Accelerator Type	F32 Throughput in TFLOPS	F16 Throughput in TFLOPS	Memory in GB
ml.eia2.medium	1	8	2
ml.eia2.large	2	16	4
ml.eia2.xlarge	4	32	8
ml.eia1.medium	1	8	1
ml.eia1.large	2	16	2
ml.eia1.xlarge	4	32	4

## Choose an EI Accelerator Type

Consider the following factors when choosing an accelerator type for a hosted model:

- Models, input tensors and batch sizes influence the amount of accelerator memory you need. Start with an accelerator type that provides at least as much memory as the file size of your trained model. Factor in that a model might use significantly more memory than the file size at runtime.

- Demands on CPU compute resources, main system memory, and GPU-based acceleration and accelerator memory vary significantly between different kinds of deep learning models. The latency and throughput requirements of the application also determine the amount of compute and acceleration you need. Thoroughly test different configurations of instance types and EI accelerator sizes to make sure you choose the configuration that best fits the performance needs of your application.

For more information on selecting an EI accelerator, see:

- [Amazon Elastic Inference Overview](#)
- [Choosing an Instance and Accelerator Type for Your Model](#)
- [Optimizing costs in Amazon Elastic Inference with TensorFlow](#)

## Use EI in a SageMaker Notebook Instance

Typically, you build and test machine learning models in a SageMaker notebook before you deploy them for production. You can attach EI to your notebook instance when you create the notebook instance. You can set up an endpoint that is hosted locally on the notebook instance by using the local mode supported by TensorFlow, MXNet, and PyTorch estimators and models in the [Amazon SageMaker Python SDK](#) to test inference performance. Elastic Inference enabled PyTorch is not currently supported on notebook instances. For instructions on how to attach EI to a notebook instance and set up a local endpoint for inference, see [Attach EI to a Notebook Instance \(p. 1882\)](#). There are also Elastic Inference-enabled SageMaker Notebook Jupyter kernels for Elastic Inference-enabled versions of TensorFlow and Apache MXNet. For information about using SageMaker notebook instances, see [Use Amazon SageMaker Notebook Instances](#)

## Use EI on a Hosted Endpoint

When you are ready to deploy your model for production to provide inferences, you create a SageMaker hosted endpoint. You can attach EI to the instance where your endpoint is hosted to increase its performance at providing inferences. For instructions on how to attach EI to a hosted endpoint instance, see [Use EI on Amazon SageMaker Hosted Endpoints \(p. 1884\)](#).

## Frameworks that Support EI

Amazon Elastic Inference is designed to be used with Amazon enhanced versions of TensorFlow, Apache MXNet, or PyTorch machine learning frameworks. These enhanced versions of the frameworks are automatically built into containers when you use the Amazon SageMaker Python SDK, or you can download them as binary files and import them in your own Docker containers.

You can download the EI-enabled TensorFlow binary files from the public [amazonei-tensorflow](#) Amazon S3 bucket to the TensorFlow serving containers. For more information about building a container that uses the EI-enabled version of TensorFlow, see [Amazon Elastic Inference with TensorFlow in SageMaker](#).

You can download the EI-enabled MXNet binary files from the public [amazonei-apachemxnet](#) Amazon S3 bucket to the MXNet serving containers. For more information about building a container that uses the EI-enabled version of MXNet, see [Amazon Elastic Inference with MXNet in SageMaker](#).

You can download the EI-enabled PyTorch binary files from the public [amazonei-pytorch](#) Amazon S3 bucket to the PyTorch serving containers. For more information about building a container that uses the EI-enabled version of PyTorch, see [Amazon Elastic Inference with PyTorch in SageMaker](#).

To use Elastic Inference in a hosted endpoint, you can choose any of the following frameworks depending on your needs.

- [SageMaker Python SDK - Deploy TensorFlow models](#)
- [SageMaker Python SDK - Deploy MXNet models](#)
- [SageMaker Python SDK - Deploy PyTorch models](#)

If you need to create a custom container for deploying your model that is complex and requires extensions to a framework that the SageMaker pre-built containers do not support, use [the low-level Amazon SDK for Python \(Boto 3\)](#).

## Use EI with SageMaker Built-in Algorithms

Currently, the [Image Classification Algorithm \(p. 1399\)](#) and [Object Detection Algorithm \(p. 1479\)](#) built-in algorithms support EI. For an example that uses the Image Classification algorithm with EI, see [End-to-End Multiclass Image Classification Example](#).

## EI Sample Notebooks

The following Sample notebooks provide examples of using EI in SageMaker:

- [Using Amazon Elastic Inference with MXNet on Amazon SageMaker](#)
- [Using Amazon Elastic Inference with MXNet on an Amazon SageMaker Notebook Instance](#)
- [Using Amazon Elastic Inference with Neo-compiled TensorFlow model on SageMaker](#)
- [Using Amazon Elastic Inference with a pre-trained TensorFlow Serving model on SageMaker](#)

## Set Up to Use EI

Use the instructions in this topic only if one of the following applies to you:

- You want to use a customized role or permission policy.
- You want to use a VPC for your hosted model or notebook instance.

### Note

If you already have an execution role that has the `AmazonSageMakerFullAccess` managed policy attached (this is true for any IAM role that you create when you create a notebook instance, training job, or model in the console) and you are not connecting to an EI model or notebook instance in a VPC, you do not need to make any of these changes to use EI in Amazon SageMaker.

### Topics

- [Set Up Required Permissions \(p. 1879\)](#)
- [Use a Custom VPC to Connect to EI \(p. 1882\)](#)

## Set Up Required Permissions

To use EI in SageMaker, the role that you use to open a notebook instance or create a deployable model must have a policy with the required permissions attached. You can attach the `AmazonSageMakerFullAccess` managed policy, which contains the required permissions, to the role, or you can add a custom policy that has the required permissions. For information about creating an IAM role, see [Creating a Role for an Amazon Service \(Console\)](#) in the *Amazon Identity and Access Management User Guide*. For information about attaching a policy to a role, see [Adding and Removing IAM Policies](#).

Add these permissions specifically for connecting EI in an IAM policy.

```
{  
    "Effect": "Allow",  
    "Action": [  
        "elastic-inference:Connect",  
        "ec2:DescribeVpcEndpoints"  
    ],  
    "Resource": "*"  
}
```

The following IAM policy is the complete list of required permissions to use EI in SageMaker.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": [  
                "elastic-inference:Connect",  
                "ec2:DescribeVpcEndpoints"  
            ],  
            "Resource": "*"  
        },  
        {  
            "Effect": "Allow",  
            "Action": [  
                "sagemaker:*"  
            ],  
            "Resource": "*"  
        },  
        {  
            "Effect": "Allow",  
            "Action": [  
                "ecr:GetAuthorizationToken",  
                "ecr:GetDownloadUrlForLayer",  
                "ecr:BatchGetImage",  
                "ecr:BatchCheckLayerAvailability",  
                "cloudwatch:PutMetricData",  
                "cloudwatch:PutMetricAlarm",  
                "cloudwatch:DescribeAlarms",  
                "cloudwatch:DeleteAlarms",

]
}

```

## Use a Custom VPC to Connect to EI

To use EI with SageMaker in a VPC, you need to create and configure two security groups, and set up a PrivateLink VPC interface endpoint. EI uses VPC interface endpoint to communicate with SageMaker endpoints in your VPC. The security groups you create are used to connect to the VPC interface endpoint.

### Set up Security Groups to Connect to EI

To use EI within a VPC, you need to create two security groups:

- A security group to control access to the VPC interface endpoint that you will set up for EI.
- A security group that allows SageMaker to call into the first security group.

#### To configure the two security groups

1. Create a security group with no outbound connections. You will attach this to the VPC endpoint interface you create in the next section.
2. Create a second security group with no inbound connections, but with an outbound connection to the first security group.
3. Edit the first security group to allow inbound connections only to the second security group and all outbound connections.

For more information about VPC security groups, see [Security Groups for Your VPC](#) in the *Amazon Virtual Private Cloud User Guide*.

### Set up a VPC Interface Endpoint to Connect to EI

To use EI with SageMaker in a custom VPC, you need to set up a VPC interface endpoint (PrivateLink) for the EI service.

- Set up a VPC interface endpoint (PrivateLink) for the EI. Follow the instructions at [Creating an Interface Endpoint](#). In the list of services, choose **com.amazonaws.<region>.elastic-inference.runtime**. For **Security group**, make sure you select the first security group you created in the previous section to the endpoint.
- When you set up the interface endpoint, choose all of the Availability Zones where EI is available. EI fails if you do not set up at least two Availability Zones. For information about VPC subnets, see [VPCs and Subnets](#).

## Attach EI to a Notebook Instance

To test and evaluate inference performance using EI, you can attach EI to a notebook instance when you create or update a notebook instance. You can then use EI in local mode to host a model at an endpoint hosted on the notebook instance. You should test various sizes of notebook instances and EI accelerators to evaluate the configuration that works best for your use case.

### Set Up to Use EI

To use EI locally in a notebook instance, create a notebook instance with an EI instance.

#### To create a notebook instance with an EI instance

1. Open the Amazon SageMaker console at <https://console.amazonaws.cn/sagemaker/>.

2. In the navigation pane, choose **Notebook instances**.
3. Choose **Create notebook instance**.
4. For **Notebook instance name**, provide a unique name for your notebook instance.
5. For **notebook instance type**, choose a CPU instance such as ml.t2.medium.
6. For **Elastic Inference (EI)**, choose an instance from the list, such as **ml.eia2.medium**.
7. For **IAM role**, choose an IAM role that has the required permissions to use SageMaker and EI.
8. (Optional) For **VPC - Optional**, if you want the notebook instance to use a VPC, choose one from the available list. Otherwise, leave it as **No VPC**. If you use a VPC follow the instructions at [Use a Custom VPC to Connect to EI \(p. 1882\)](#).
9. (Optional) For **Lifecycle configuration - optional**, either leave it as **No configuration** or choose a lifecycle configuration. For more information, see [Customize a Notebook Instance Using a Lifecycle Configuration Script \(p. 124\)](#).
10. (Optional) For **Encryption key - optional**, if you want SageMaker to use an Amazon Key Management Service (Amazon KMS) key to encrypt data in the ML storage volume attached to the notebook instance, specify the key.
11. (Optional) For **Volume Size In GB - optional**, leave the default value of 5.
12. (Optional) For **Tags**, add tags to the notebook instance. A tag is a label you assign to help manage your notebook instances. A tag consists of a key and a value, both of which you define.
13. Choose **Create Notebook Instance**.

After you create your notebook instance with EI attached, you can create a Jupyter notebook and set up an EI endpoint that is hosted locally on the notebook instance.

#### Topics

- [Use EI in Local Mode in SageMaker \(p. 1883\)](#)

## Use EI in Local Mode in SageMaker

To use EI locally in an endpoint hosted on a notebook instance, use local mode with the [Amazon SageMaker Python SDK](#) versions of either the TensorFlow, MXNet, or PyTorch estimators or models. For more information about local mode support in the SageMaker Python SDK, see <https://github.com/aws/sagemaker-python-sdk#sagemaker-python-sdk-overview>.

#### Topics

- [Use EI in Local Mode with SageMaker TensorFlow Estimators and Models \(p. 1883\)](#)
- [Use EI in Local Mode with SageMaker Apache MXNet Estimators and Models \(p. 1884\)](#)
- [Use EI in Local Mode with SageMaker PyTorch Estimators and Models \(p. 1884\)](#)

## Use EI in Local Mode with SageMaker TensorFlow Estimators and Models

To use EI with TensorFlow in local mode, specify `local` for `instance_type` and `local_sagemaker_notebook` for `accelerator_type` when you call the `deploy` method of an estimator or a model object. For more information about [Amazon SageMaker Python SDK](#) TensorFlow estimators and models, see <https://sagemaker.readthedocs.io/en/stable/frameworks/tensorflow/index.html>.

The following code shows how to use local mode with an estimator object. To call the `deploy` method, you must have previously either:

- Trained the model by calling the `fit` method of an estimator.
- Pass a model artifact when you initialize the model object.

```
# Deploys the model to a local endpoint
tf_predictor = tf_model.deploy(initial_instance_count=1,
                               instance_type='local',
                               accelerator_type='local_sagemaker_notebook')
```

## Use EI in Local Mode with SageMaker Apache MXNet Estimators and Models

To use EI with MXNet in local mode, specify `local` for `instance_type` and `local_sagemaker_notebook` for `accelerator_type` when you call the `deploy` method of an estimator or a model object. For more information about [Amazon SageMaker Python SDK](https://sagemaker.readthedocs.io/en/stable/frameworks/mxnet/index.html) MXNet estimators and models, see <https://sagemaker.readthedocs.io/en/stable/frameworks/mxnet/index.html>.

The following code shows how to use local mode with an estimator object. You must have previously called the `fit` method of the estimator to train the model.

```
# Deploys the model to a local endpoint
mxnet_predictor = mxnet_estimator.deploy(initial_instance_count=1,
                                         instance_type='local',
                                         accelerator_type='local_sagemaker_notebook')
```

For a complete example of using EI in local mode with MXNet, see the sample notebook at [https://sagemaker-examples.readthedocs.io/en/latest/sagemaker-python-sdk/mxnet\\_mnist/mxnet\\_mnist\\_elastic\\_inference\\_local.html](https://sagemaker-examples.readthedocs.io/en/latest/sagemaker-python-sdk/mxnet_mnist/mxnet_mnist_elastic_inference_local.html).

## Use EI in Local Mode with SageMaker PyTorch Estimators and Models

To use EI with PyTorch in local mode, when you call the `deploy` method of an estimator or a model object, specify `local` for `instance_type` and `local_sagemaker_notebook` for `accelerator_type`. For more information about [Amazon SageMaker Python SDK](#) PyTorch estimators and models, see [SageMaker PyTorch Estimators and Models](#).

The following code shows how to use local mode with an estimator object. You must have previously called the `fit` method of the estimator to train the model.

```
# Deploys the model to a local endpoint
pytorch_predictor = pytorch_estimator.deploy(initial_instance_count=1,
                                              instance_type='local',
                                              accelerator_type='local_sagemaker_notebook')
```

## Use EI on Amazon SageMaker Hosted Endpoints

To use Elastic Inference (EI) in Amazon SageMaker with a hosted endpoint for real-time inference, specify an EI accelerator when you create the deployable model to be hosted at that endpoint. You can do this in one of the following ways:

- Use the [Amazon SageMaker Python SDK](#) versions of either the TensorFlow, MXNet, or PyTorch and the SageMaker pre-built containers for TensorFlow, MXNet, and PyTorch
- Build your own container, and use the low-level SageMaker API (Boto 3). You will need to import the EI-enabled version of either TensorFlow, MXNet, or PyTorch from the provided Amazon S3 locations into your container, and use one of those versions to write your training script.
- Use either the [Image Classification Algorithm \(p. 1399\)](#) or [Object Detection Algorithm \(p. 1479\)](#) build-in algorithms, and use the Amazon SDK for Python (Boto3) to run your training job and create your deployable model and hosted endpoint.

### Topics

- [Use EI with a SageMaker TensorFlow Container \(p. 1885\)](#)
- [Use EI with a SageMaker MXNet Container \(p. 1885\)](#)
- [Use EI with a SageMaker PyTorch Container \(p. 1886\)](#)
- [Use EI with Your Own Container \(p. 1886\)](#)

## Use EI with a SageMaker TensorFlow Container

To use TensorFlow with EI in SageMaker, you need to call the `deploy` method of either the [Estimator](#) or [Model](#) objects. You then specify an accelerator type using the `accelerator_type` input argument. For information on using TensorFlow in the SageMaker Python SDK, see: <https://sagemaker.readthedocs.io/en/stable/frameworks/tensorflow/index.html>.

SageMaker provides default model training and inference code for your convenience. For custom file formats, you might need to implement custom model training and inference code.

### Use an Estimator Object

To use an estimator object with EI, when you use the `deploy` method, include the `accelerator_type` input argument. The estimator returns a predictor object, which we call its `deploy` method, as shown in the example code.

```
# Deploy an estimator using EI (using the accelerator_type input argument)
predictor = estimator.deploy(initial_instance_count=1,
                             instance_type='ml.m4.xlarge',
                             accelerator_type='ml.eia2.medium')
```

### Use a Model Object

To use a model object with EI, when you use the `deploy` method, include the `accelerator_type` input argument. The estimator returns a predictor object, which we call its `deploy` method, as shown in the example code.

```
# Deploy a model using EI (using the accelerator_type input argument)
predictor = model.deploy(initial_instance_count=1,
                        instance_type='ml.m4.xlarge',
                        accelerator_type='ml.eia2.medium')
```

## Use EI with a SageMaker MXNet Container

To use MXNet with EI in SageMaker, you need to call the `deploy` method of either the [Estimator](#) or [Model](#) objects. You then specify an accelerator type using the `accelerator_type` input argument. For information about using MXNet in the [Amazon SageMaker Python SDK](#), see <https://sagemaker.readthedocs.io/en/stable/frameworks/mxnet/index.html>

For your convenience, SageMaker provides default model training and inference code. For custom file formats, you might need to write custom model training and inference code.

### Use an Estimator Object

To use an estimator object with EI, when you use the `deploy` method, include the `accelerator_type` input argument. The estimator returns a predictor object, which we call its `deploy` method, as shown in the example code.

```
# Deploy an estimator using EI (using the accelerator_type input argument)
```

```
predictor = estimator.deploy(initial_instance_count=1,  
                             instance_type='ml.m4.xlarge',  
                             accelerator_type='ml.eia2.medium')
```

## Use a Model Object

To use a model object with EI, when you use the `deploy` method, include the `accelerator_type` input argument. The estimator returns a predictor object, which we call its `deploy` method, as shown in the example code.

```
# Deploy a model using EI (using the accelerator_type input argument)  
predictor = model.deploy(initial_instance_count=1,  
                         instance_type='ml.m4.xlarge',  
                         accelerator_type='ml.eia2.medium')
```

For a complete example of using EI with MXNet in SageMaker, see the sample notebook at [https://github.com/awslabs/amazon-sagemaker-examples/blob/master/sagemaker-python-sdk/mxnet\\_mnist/mxnet\\_mnist\\_elastic\\_inference.ipynb](https://github.com/awslabs/amazon-sagemaker-examples/blob/master/sagemaker-python-sdk/mxnet_mnist/mxnet_mnist_elastic_inference.ipynb)

## Use EI with a SageMaker PyTorch Container

To use PyTorch with EI in SageMaker, you need to call the `deploy` method of either the [Estimator](#) or [Model](#) objects. You then specify an accelerator type using the `accelerator_type` input argument. For information about using PyTorch in the [Amazon SageMaker Python SDK](#), see [SageMaker PyTorch Estimators and Models](#).

For your convenience, SageMaker provides default model training and inference code. For custom file formats, you might need to write custom model training and inference code.

## Use an Estimator Object

To use an estimator object with EI, when you use the `deploy` method, include the `accelerator_type` input argument. The estimator returns a predictor object, which we call its `deploy` method, as shown in this example code.

```
# Deploy an estimator using EI (using the accelerator_type input argument)  
predictor = estimator.deploy(initial_instance_count=1,  
                             instance_type='ml.m4.xlarge',  
                             accelerator_type='ml.eia2.medium')
```

## Use a Model Object

To use a model object with EI, when you use the `deploy` method, include the `accelerator_type` input argument. The model returns a predictor object, which we call its `deploy` method, as shown in this example code.

```
# Deploy a model using EI (using the accelerator_type input argument)  
predictor = model.deploy(initial_instance_count=1,  
                         instance_type='ml.m4.xlarge',  
                         accelerator_type='ml.eia2.medium')
```

## Use EI with Your Own Container

To use EI with a model in a custom container that you build, use the low-level Amazon SDK for Python (Boto 3), download and import the Amazon EI-enabled versions of TensorFlow, Apache MXNet, or PyTorch machine learning frameworks, and write your training script using those frameworks.

## Import the EI Version of TensorFlow, MXNet, or PyTorch into Your Docker Container

To use EI with your own container, you need to import either the Amazon EI TensorFlow Serving library, the Amazon EI Apache MXNet library, or the Elastic Inference enabled PyTorch library into your container. The EI-enabled versions of TensorFlow and MXNet are currently available as binary files stored in Amazon S3 locations. You can download the EI-enabled binary for TensorFlow from the Amazon S3 bucket at [console.amazonaws.cn/s3/buckets/amazonei-tensorflow](https://console.amazonaws.cn/s3/buckets/amazonei-tensorflow). For information about building a container that uses the EI-enabled version of TensorFlow, see <https://github.com/aws/sagemaker-tensorflow-container#building-the-sagemaker-elastic-inference-tensorflow-serving-container>. You can download the EI-enabled binary for Apache MXNet from the public Amazon S3 bucket at [console.amazonaws.cn/s3/buckets/amazonei-apachemxnet](https://console.amazonaws.cn/s3/buckets/amazonei-apachemxnet). For information about building a container that uses the EI-enabled version of MXNet, see <https://github.com/aws/sagemaker-mxnet-container#building-the-sagemaker-elastic-inference-mxnet-container>. You can download the Elastic Inference enabled binary for PyTorch from the public Amazon S3 bucket at [console.amazonaws.cn/s3/buckets/amazonei-pytorch](https://console.amazonaws.cn/s3/buckets/amazonei-pytorch). For information about building a container that uses the Elastic Inference enabled version of PyTorch, see [Building your image](#).

## Create an EI Endpoint with Amazon SDK for Python (Boto 3)

To create an endpoint by using Amazon SDK for Python (Boto 3), you first create an endpoint configuration. The endpoint configuration specifies one or more models (called production variants) that you want to host at the endpoint. To attach EI to one or more of the production variants hosted at the endpoint, you specify one of the EI instance types as the `AcceleratorType` field for that `ProductionVariant`. You then pass that endpoint configuration when you create the endpoint.

### Create an Endpoint Configuration

To use EI, you need to specify an accelerator type in the endpoint configuration.

```
# Create Endpoint Configuration
from time import gmtime, strftime

endpoint_config_name = 'ImageClassificationEndpointConfig-' + strftime("%Y-%m-%d-%H-%M-%S",
    gmtime())
print(endpoint_config_name)
create_endpoint_config_response = sagemaker.create_endpoint_config(
    EndpointConfigName = endpoint_config_name,
    ProductionVariants=[{
        'InstanceType': 'ml.m4.xlarge',
        'InitialInstanceCount': 1,
        'ModelName': model_name,
        'VariantName': 'AllTraffic',
        'AcceleratorType': 'ml.eia2.medium'}])

print("Endpoint Config Arn: " + create_endpoint_config_response['EndpointConfigArn'])
```

### Create an Endpoint

After you create an endpoint configuration with an accelerator type, you can create an endpoint.

```
endpoint_name = 'ImageClassificationEndpoint-' + strftime("%Y-%m-%d-%H-%M-%S", gmtime())
endpoint_response = sagemaker.create_endpoint(
    EndpointName=endpoint_name,
    EndpointConfigName=endpoint_config_name)
```

After creating the endpoint, you can invoke it using the `invoke_endpoint` method in a Boto3 runtime object, as you would any other endpoint.

# Use Batch Transform

Use batch transform when you need to do the following:

- Preprocess datasets to remove noise or bias that interferes with training or inference from your dataset.
- Get inferences from large datasets.
- Run inference when you don't need a persistent endpoint.
- Associate input records with inferences to assist the interpretation of results.

To filter input data before performing inferences or to associate input records with inferences about those records, see [Associate Prediction Results with Input Records \(p. 1890\)](#). For example, you can filter input data to provide context for creating and interpreting reports about the output data.

For more information about batch transforms, see [Get Inferences for an Entire Dataset with Batch Transform \(p. 13\)](#).

## Topics

- [Use Batch Transform to Get Inferences from Large Datasets \(p. 1888\)](#)
- [Speed up a Batch Transform Job \(p. 1889\)](#)
- [Use Batch Transform to Test Production Variants \(p. 1889\)](#)
- [Batch Transform Errors \(p. 1890\)](#)
- [Batch Transform Sample Notebooks \(p. 1890\)](#)
- [Associate Prediction Results with Input Records \(p. 1890\)](#)

## Use Batch Transform to Get Inferences from Large Datasets

Batch transform automatically manages the processing of large datasets within the limits of specified parameters. For example, suppose that you have a dataset file, `input1.csv`, stored in an S3 bucket. The content of the input file might look like the following.:

```
Record1-Attribute1, Record1-Attribute2, Record1-Attribute3, ..., Record1-AttributeM  
Record2-Attribute1, Record2-Attribute2, Record2-Attribute3, ..., Record2-AttributeM  
Record3-Attribute1, Record3-Attribute2, Record3-Attribute3, ..., Record3-AttributeM  
...  
RecordN-Attribute1, RecordN-Attribute2, RecordN-Attribute3, ..., RecordN-AttributeM
```

When a batch transform job starts, SageMaker initializes compute instances and distributes the inference or preprocessing workload between them. Batch Transform partitions the Amazon S3 objects in the input by key and maps Amazon S3 objects to instances. When you have multiple files, one instance might process `input1.csv`, and another instance might process the file named `input2.csv`.

To keep large payloads below the `MaxPayloadInMB` limit, you can split an input file into several mini-batches. For example, you might create a mini-batch from `input1.csv` by including only two of the records.

```
Record3-Attribute1, Record3-Attribute2, Record3-Attribute3, ..., Record3-AttributeM  
Record4-Attribute1, Record4-Attribute2, Record4-Attribute3, ..., Record4-AttributeM
```

**Note**

SageMaker processes each input file separately. It doesn't combine mini-batches from different input files to comply with the [MaxPayloadInMB](#) limit.

To split input files into mini-batches, when you create a batch transform job, set the [SplitType](#) parameter value to `Line`. If `SplitType` is set to `None` or if an input file can't be split into mini-batches, SageMaker uses the entire input file in a single request.

If the batch transform job successfully processes all of the records in an input file, it creates an output file with the same name and the `.out` file extension. For multiple input files, such as `input1.csv` and `input2.csv`, the output files are named `input1.csv.out` and `input2.csv.out`. The batch transform job stores the output files in the specified location in Amazon S3, such as `s3://awsexamplebucket/output/`.

The predictions in an output file are listed in the same order as the corresponding records in the input file. The output file `input1.csv.out`, based on the input file shown earlier, would look like the following.

```
Inference1-Attribute1, Inference1-Attribute2, Inference1-Attribute3, ..., Inference1-AttributeM
Inference2-Attribute1, Inference2-Attribute2, Inference2-Attribute3, ..., Inference2-AttributeM
Inference3-Attribute1, Inference3-Attribute2, Inference3-Attribute3, ..., Inference3-AttributeM
...
InferenceN-Attribute1, InferenceN-Attribute2, InferenceN-Attribute3, ..., InferenceN-AttributeM
```

To combine the results of multiple output files into a single output file, set the [AssembleWith](#) parameter to `Line`.

When the input data is very large and is transmitted using HTTP chunked encoding, to stream the data to the algorithm, set [MaxPayloadInMB](#) to 0. Amazon SageMaker built-in algorithms don't support this feature.

For information about using the API to create a batch transform job, see the [CreateTransformJob](#) API. For more information about the correlation between batch transform input and output objects, see [OutputDataConfig](#). For an example of how to use batch transform, see [\(Optional\) Make Prediction with Batch Transform \(p. 64\)](#).

## Speed up a Batch Transform Job

If you are using the [CreateTransformJob](#) API, you can reduce the time it takes to complete batch transform jobs by using optimal values for parameters such as [MaxPayloadInMB](#), [MaxConcurrentTransforms](#), or [BatchStrategy](#). If you are using the SageMaker console, you can specify these optimal parameter values in the **Additional configuration** section of the **Batch transform job configuration** page. SageMaker automatically finds the optimal parameter settings for built-in algorithms. For custom algorithms, provide these values through an [execution-parameters](#) endpoint.

## Use Batch Transform to Test Production Variants

To test different models or various hyperparameter settings, create a separate transform job for each new model variant and use a validation dataset. For each transform job, specify a unique model name and location in Amazon S3 for the output file. To analyze the results, use [Inference Pipeline Logs and Metrics \(p. 1924\)](#).

## Batch Transform Errors

SageMaker uses the Amazon S3 [Multipart Upload API](#) to upload results from a batch transform job to Amazon S3. If an error occurs, the uploaded results are removed from Amazon S3. In some cases, such as when a network outage occurs, an incomplete multipart upload might remain in Amazon S3. To avoid incurring storage charges, we recommend that you add the [S3 bucket policy](#) to the S3 bucket lifecycle rules. This policy deletes incomplete multipart uploads that might be stored in the S3 bucket. For more information, see [Object Lifecycle Management](#).

If a batch transform job fails to process an input file because of a problem with the dataset, SageMaker marks the job as `Failed`. If an input file contains a bad record, the transform job doesn't create an output file for that input file because doing so prevents it from maintaining the same order in the transformed data as in the input file. When your dataset has multiple input files, a transform job continues to process input files even if it fails to process one. The processed files still generate useable results.

Exceeding the [MaxPayloadInMB](#) limit causes an error. This might happen with a large dataset if it can't be split, the [SplitType](#) parameter is set to `none`, or individual records within the dataset exceed the limit.

If you are using your own algorithms, you can use placeholder text, such as `ERROR`, when the algorithm finds a bad record in an input file. For example, if the last record in a dataset is bad, the algorithm places the placeholder text for that record in the output file.

## Batch Transform Sample Notebooks

For a sample notebook that uses batch transform with a principal component analysis (PCA) model to reduce data in a user-item review matrix, followed by the application of a density-based spatial clustering of applications with noise (DBSCAN) algorithm to cluster movies, see [Batch Transform with PCA and DBSCAN Movie Clusters](#). For instructions on creating and accessing Jupyter notebook instances that you can use to run the example in SageMaker, see [Use Amazon SageMaker Notebook Instances \(p. 120\)](#). After creating and opening a notebook instance, choose the **SageMaker Examples** tab to see a list of all the SageMaker examples. The topic modeling example notebooks that use the NTM algorithms are located in the **Advanced functionality** section. To open a notebook, choose its **Use** tab, then choose **Create copy**.

## Associate Prediction Results with Input Records

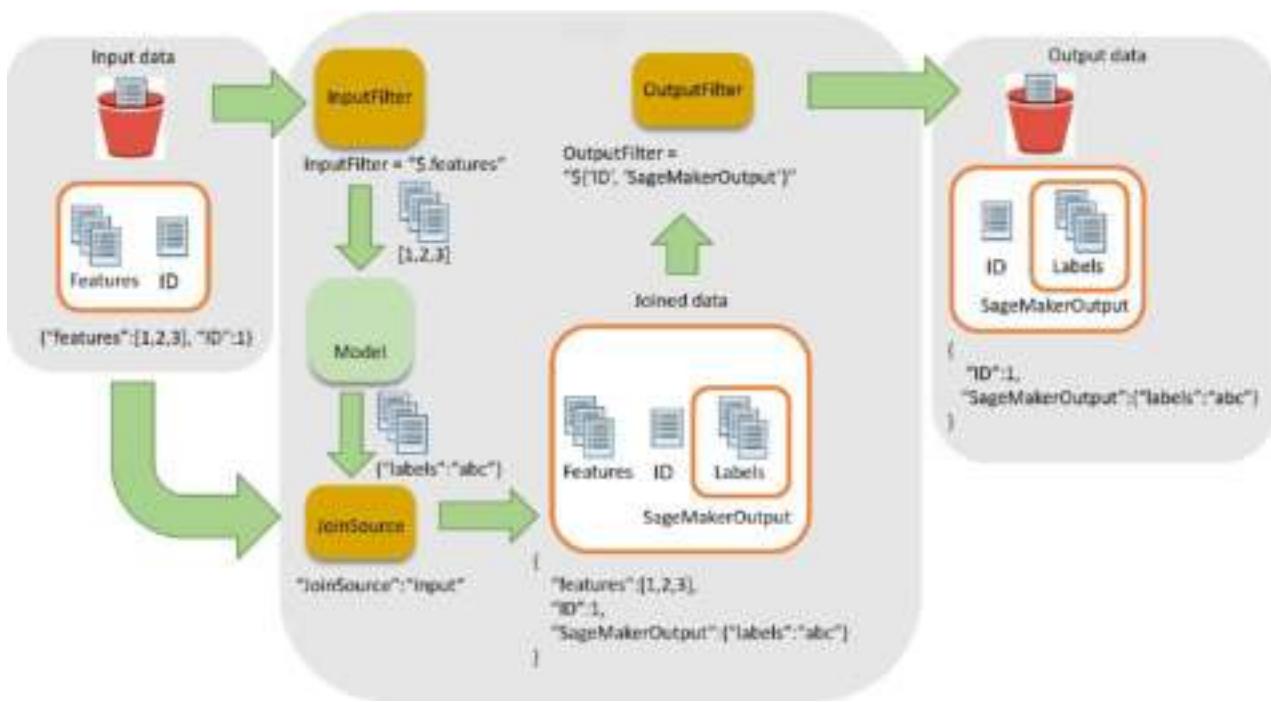

When making predictions on a large dataset, you can exclude attributes that aren't needed for prediction. After the predictions have been made, you can associate some of the excluded attributes with those predictions or with other input data in your report. By using batch transform to perform these data processing steps, you can often eliminate additional preprocessing or postprocessing. You can use input files in JSON and CSV format only.

### Topics

- [Workflow for Associating Inferences with Input Records \(p. 1890\)](#)
- [Use Data Processing in Batch Transform Jobs \(p. 1891\)](#)
- [Supported JSONPath Operators \(p. 1892\)](#)
- [Batch Transform Examples \(p. 1892\)](#)

## Workflow for Associating Inferences with Input Records

The following diagram shows the workflow for associating inferences with input records.

To associate inferences with input data, there are three main steps:

1. Filter the input data that is not needed for inference before passing the input data to the batch transform job. Use the [InputFilter](#) parameter to determine which attributes to use as input for the model.
2. Associate the input data with the inference results. Use the [JoinSource](#) parameter to combine the input data with the inference.
3. Filter the joined data to retain the inputs that are needed to provide context for interpreting the predictions in the reports. Use [OutputFilter](#) to store the specified portion of the joined dataset in the output file.

## Use Data Processing in Batch Transform Jobs

When creating a batch transform job with [CreateTransformJob](#) to process data:

1. Specify the portion of the input to pass to the model with the [InputFilter](#) parameter in the [DataProcessing](#) data structure.
2. Join the raw input data with the transformed data with the [JoinSource](#) parameter.
3. Specify which portion of the joined input and transformed data from the batch transform job to include in the output file with the [OutputFilter](#) parameter.
4. Choose either JSON- or CSV-formatted files for input:
  - For JSON- or JSON Lines-formatted input files, SageMaker either adds the [SageMakerOutput](#) attribute to the input file or creates a new JSON output file with the [SageMakerInput](#) and [SageMakerOutput](#) attributes. For more information, see [DataProcessing](#).
  - For CSV-formatted input files, the joined input data is followed by the transformed data and the output is a CSV file.

If you use an algorithm with the [DataProcessing](#) structure, it must support your chosen format for *both* input and output files. For example, with the [TransformOutput](#) field of the

CreateTransformJob API, you must set both the `Content Type` and `Accept` parameters to one of the following values: `text/csv`, `application/json`, or `application/jsonlines`. The syntax for specifying columns in a CSV file and specifying attributes in a JSON file are different. Using the wrong syntax causes an error. For more information, see [Batch Transform Examples \(p. 1892\)](#). For more information about input and output file formats for built-in algorithms, see [Use Amazon SageMaker Built-in Algorithms \(p. 718\)](#).

The record delimiters for the input and output must also be consistent with your chosen file input. The `SplitType` parameter indicates how to split the records in the input dataset. The `AssembleWith` parameter indicates how to reassemble the records for the output. If you set input and output formats to `text/csv`, you must also set the `SplitType` and `AssemblyType` parameters to `line`. If you set the input and output formats to `application/jsonlines`, you can set both `SplitType` and `AssemblyType` to `line`.

For JSON files, the attribute name `SageMakerOutput` is reserved for output. The JSON input file can't have an attribute with this name. If it does, the data in the input file might be overwritten.

## Supported JSONPath Operators

To filter and join the input data and inference, use a JSONPath subexpression. SageMaker supports only a subset of the defined JSONPath operators. The following table lists the supported JSONPath operators. For CSV data, each row is taken as a JSON array, so only index based JSONPaths can be applied, e.g. `[$[0], $[1 : ]]`. CSV data should also follow [RFC format](#).

JSONPath Operator	Description	Example
<code>\$</code>	The root element to a query. This operator is required at the beginning of all path expressions.	<code>\$</code>
<code>.&lt;name&gt;</code>	A dot-notated child element.	<code>\$.id</code>
<code>*</code>	A wildcard. Use in place of an attribute name or numeric value.	<code>\$.id.*</code>
<code>['&lt;name&gt;' (, '&lt;name&gt;')]</code>	A bracket-notated element or multiple child elements.	<code>\$['id', 'SageMakerOutput']</code>
<code>[&lt;number&gt; (, &lt;number&gt;)]</code>	An index or array of indexes. Negative index values are also supported. A <code>-1</code> index refers to the last element in an array.	<code>\$[1], \$[1, 3, 5]</code>
<code>[&lt;start&gt;:&lt;end&gt;]</code>	An array slice operator. The <code>array slice()</code> method extracts a section of an array and returns a new array. If you omit <code>&lt;start&gt;</code> , SageMaker uses the first element of the array. If you omit <code>&lt;end&gt;</code> , SageMaker uses the last element of the array.	<code>\$[2:5], \$[:5], \$[2:]</code>

When using the bracket-notation to specify multiple child elements of a given field, additional nesting of children within brackets is not supported. For example, `$.field1.[ 'child1', 'child2' ]` is supported while `$.field1.[ 'child1', 'child2.grandchild' ]` is not.

For more information about JSONPath operators, see [JsonPath](#) on GitHub.

## Batch Transform Examples

The following examples show some common ways to join input data with prediction results.

## Topics

- [Example: Output Only Inferences \(p. 1893\)](#)
- [Example: Output Input Data and Inferences \(p. 1893\)](#)
- [Example: Output an ID Column with Results and Exclude the ID Column from the Input \(CSV\) \(p. 1894\)](#)
- [Example: Output an ID Attribute with Results and Exclude the ID Attribute from the Input \(JSON\) \(p. 1894\)](#)

## Example: Output Only Inferences

By default, the `DataProcessing` parameter doesn't join inference results with input. It outputs only the inference results.

If you want to explicitly specify to not join results with input, use the [Amazon SageMaker Python SDK](#) and specify the following settings in a transformer call.

```
sm_transformer = sagemaker.transformer.Transformer(...)  
sm_transformer.transform(..., input_filter="$", join_source= "None", output_filter="$")
```

To output inferences using the Amazon SDK for Python, add the following code to your `CreateTransformJob` request. The following code mimics the default behavior.

```
{  
    "DataProcessing": {  
        "InputFilter": "$",  
        "JoinSource": "None",  
        "OutputFilter": "$"  
    }  
}
```

## Example: Output Input Data and Inferences

If you're using the [Amazon SageMaker Python SDK](#), to combine the input data with the inferences in the output file, specify "Input" for the `JoinSource` parameter in a transformer call.

```
sm_transformer = sagemaker.transformer.Transformer(...)  
sm_transformer.transform(..., join_source= "Input")
```

If you're using the Amazon SDK for Python (Boto 3), join all input data with the inference by adding the following code to your `CreateTransformJob` request.

```
{  
    "DataProcessing": {  
        "JoinSource": "Input"  
    }  
}
```

For JSON or JSON Lines input files, the results are in the `SageMakerOutput` key in the input JSON file. For example, if the input is a JSON file that contains the key-value pair `{"key":1}`, the data transform result might be `{"label":1}`.

SageMaker stores both in the input file in the `SageMakerInput` key.

```
{
  "key":1,
  "SageMakerOutput":{"label":1}
}
```

#### Note

The joined result for JSON must be a key-value pair object. If the input isn't a key-value pair object, SageMaker creates a new JSON file. In the new JSON file, the input data is stored in the `SageMakerInput` key and the results are stored as the `SageMakerOutput` value.

For a CSV file, for example, if the record is [1, 2, 3], and the label result is [1], then the output file would contain [1, 2, 3, 1].

### Example: Output an ID Column with Results and Exclude the ID Column from the Input (CSV)

If you are using the [Amazon SageMaker Python SDK](#), to include results or an ID column in the output, specify indexes of the joined dataset in a transformer call. For example, if your data includes five columns and the first one is the ID column, use the following transformer request.

```
sm_transformer = sagemaker.transformer.Transformer(...)
sm_transformer.transform(..., input_filter="[$[1:]", join_source= "Input", output_filter="$")
```

If you are using the Amazon SDK for Python (Boto 3), add the following code to your [CreateTransformJob](#) request.

```
{
  "DataProcessing": {
    "InputFilter": "$[1:]",
    "JoinSource": "Input",
    "OutputFilter": "$"
  }
}
```

To specify columns in SageMaker, use the index of the array elements. The first column is index 0, the second column is index 1, and the sixth column is index 5.

To exclude the first column from the input, set `InputFilter` to `"[$[1:]"`. The colon (`:`) tells SageMaker to include all of the elements between two values, inclusive. For example, `[$[1:4]` specifies the second through fifth columns.

If you omit the number after the colon, for example, `[5 : ]`, the subset includes all columns from the 6th column through the last column. If you omit the number before the colon, for example, `[:5]`, the subset includes all columns from the first column (index 0) through the sixth column.

### Example: Output an ID Attribute with Results and Exclude the ID Attribute from the Input (JSON)

If you are using the [Amazon SageMaker Python SDK](#), include results of an ID attribute in the output by specifying it in a transformer call. For example, if you store data in the `features` attribute and the record ID in the `ID` attribute, you would use the following transformer request.

```
sm_transformer = sagemaker.transformer.Transformer(...)
sm_transformer.transform(..., input_filter=".features", join_source= "Input",
                      output_filter="['id', 'SageMakerOutput']")
```

If you are using the Amazon SDK for Python (Boto 3), join all input data with the inference by adding the following code to your [CreateTransformJob](#) request.

```
{  
    "DataProcessing": {  
        "InputFilter": "$.features",  
        "JoinSource": "Input",  
        "OutputFilter": "$['id', 'SageMakerOutput']"  
    }  
}
```

**Warning**

If you are using a JSON-formatted input file, the file can't contain the attribute name `SageMakerOutput`. This attribute name is reserved for the output file. If your JSON-formatted input file contains an attribute with this name, values in the input file might be overwritten with the inference.

## Host Multiple Models with Multi-Model Endpoints

To create an endpoint that can host multiple models, use multi-model endpoints. Multi-model endpoints provide a scalable and cost-effective solution to deploying large numbers of models. They use a shared serving container that is enabled to host multiple models. This reduces hosting costs by improving endpoint utilization compared with using single-model endpoints. It also reduces deployment overhead because Amazon SageMaker manages loading models in memory and scaling them based on the traffic patterns to them.

Multi-model endpoints also enable time-sharing of memory resources across your models. This works best when the models are fairly similar in size and invocation latency. When this is the case, multi-model endpoints can effectively use instances across all models. If you have models that have significantly higher transactions per second (TPS) or latency requirements, we recommend hosting them on dedicated endpoints. Multi-model endpoints are also well suited to scenarios that can tolerate occasional cold-start-related latency penalties that occur when invoking infrequently used models.

Multi-model endpoints support A/B testing. They work with Auto Scaling and Amazon PrivateLink. You can use multi-model-enabled containers with serial inference pipelines, but only one multi-model-enabled container can be included in an inference pipeline. You can't use multi-model-enabled containers with Amazon Elastic Inference.

You can use the Amazon SDK for Python (Boto) or the SageMaker console to create a multi-model endpoint. You can use multi-model endpoints with custom-built containers by integrating the [Multi Model Server](#) library.

To use any other framework or algorithm, use the SageMaker inference toolkit to build a container that supports multi-model endpoints. For information, see [Build Your Own Container with Multi Model Server \(p. 1904\)](#).

## Sample Notebooks for Multi-Model Endpoints

For a sample notebook that uses SageMaker to deploy multiple XGBoost models to an endpoint, see the [Multi-Model Endpoint XGBoost Sample Notebook](#). For a sample notebook that shows how to set up and deploy a custom container that supports multi-model endpoints in SageMaker, see the [Multi-Model Endpoint BYOC Sample Notebook](#). For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see [Use Amazon SageMaker Notebook Instances \(p. 120\)](#). After you've created a notebook instance and opened it, choose the **SageMaker Examples** tab to see a list of all the SageMaker samples. The Multi-Model Endpoint notebook is located in the **ADVANCED FUNCTIONALITY** section. To open a notebook, choose its **Use** tab and choose **Create copy**.

## How Multi-Model Endpoints Work

SageMaker manages the lifecycle of models hosted on multi-model endpoints in the container's memory. Instead of downloading all of the models from an Amazon S3 bucket to the container when you create the endpoint, SageMaker dynamically loads them when you invoke them. When SageMaker receives an invocation request for a particular model, it does the following:

1. Routes the request to an instance behind the endpoint.
2. Downloads the model from the S3 bucket to that instance's storage volume.
3. Loads the model to the container's memory on that instance. If the model is already loaded in the container's memory, invocation is faster because SageMaker doesn't need to download and load it.

SageMaker continues to route requests for a model to the instance where the model is already loaded. However, if the model receives many invocation requests, and there are additional instances for the multi-model endpoint, SageMaker routes some requests to another instance to accommodate the traffic. If the model isn't already loaded on the second instance, the model is downloaded to that instance's storage volume and loaded into the container's memory.

When an instance's memory utilization is high and SageMaker needs to load another model into memory, it unloads unused models from that instance's container to ensure that there is enough

memory to load the model. Models that are unloaded remain on the instance's storage volume and can be loaded into the container's memory later without being downloaded again from the S3 bucket. If the instance's storage volume reaches its capacity, SageMaker deletes any unused models from the storage volume.

To delete a model, stop sending requests and delete it from the S3 bucket. SageMaker provides multi-model endpoint capability in a serving container. Adding models to, and deleting them from, a multi-model endpoint doesn't require updating the endpoint itself. To add a model, you upload it to the S3 bucket and invoke it. You don't need code changes to use it.

When you update a multi-model endpoint, invocation requests on the endpoint might experience higher latencies as traffic is directed to the instances in the updated endpoint.

## Setting SageMaker Multi-Model Endpoint Model Caching Behavior

By default, multi-model endpoints cache frequently used models in memory and on disk to provide low latency inference. The cached models are unloaded and/or deleted from disk only when a container runs out of memory or disk space to accommodate a newly targeted model.

You can change the caching behavior of a multi-model endpoint and explicitly enable or disable model caching by setting the parameter `ModelCacheSetting` when you call `create_model`.

We recommend setting the value of the `ModelCacheSetting` parameter to `Disabled` for use cases that do not benefit from model caching. For example, when a large number of models need to be served from the endpoint but each model is invoked only once (or very infrequently). For such use cases, setting the value of the `ModelCacheSetting` parameter to `Disabled` allows higher transactions per second (TPS) for `invoke_endpoint` requests compared to the default caching mode. Higher TPS in these use cases is because SageMaker does the following after the `invoke_endpoint` request:

- Asynchronously unloads the model from memory and deletes it from disk immediately after it is invoked.
- Provides higher concurrency for downloading and loading models in the inference container. The concurrency is a factor of the number of vCPUs of the container instance.

For guidelines on choosing a SageMaker ML instance type for a multi-model endpoint, see [Instance Recommendations for Multi-Model Endpoint Deployments \(p. 1897\)](#).

## Instance Recommendations for Multi-Model Endpoint Deployments

There are several items to consider when selecting a SageMaker ML instance type for a multi-model endpoint. Provision sufficient [Amazon Elastic Block Store \(Amazon EBS\)](#) capacity for all of the models that need to be served. Balance performance (minimize cold starts) and cost (don't over-provision instance capacity). For information about the size of the storage volume that SageMaker attaches for each instance type for an endpoint and for a multi-model endpoint, see [Host Instance Storage Volumes \(p. 1946\)](#). For a container configured to run in `MultiModel` mode, the storage volume provisioned for its instances has more memory. This allows more models to be cached on the instance storage volume.

When choosing a SageMaker ML instance type, consider the following:

- Multi-model endpoints are not supported on GPU instance types.

- The traffic distribution (access patterns) to the models that you want to host behind the multi-model endpoint, along with the model size (how many models could be loaded in memory on the instance):
  - Think of the amount of memory on an instance as the cache space for models to be loaded. Think of the number of vCPUs as the concurrency limit to perform inference on the loaded models (assuming that invoking a model is bound to CPU).
  - A higher amount of instance memory enables you to have more models loaded and ready to serve inference requests. You don't need to waste time loading the model.
  - A higher amount of vCPUs enables you to invoke more unique models concurrently (again assuming that inference is bound to CPU).
  - Have some "slack" memory available so that unused models can be unloaded, and especially for multi-model endpoints with multiple instances. If an instance or an Availability Zone fails, the models on those instances will be rerouted to other instances behind the endpoint.
- Tolerance to loading/downloading times:
  - d instance type families (for example, m5d, c5d, or r5d) come with an NVMe (non-volatile memory express) SSD, which offers high I/O performance and might reduce the time it takes to download models to the storage volume and for the container to load the model from the storage volume.
  - Because d instance types come with an NVMe SSD storage, SageMaker does not attach an Amazon EBS storage volume to these ML compute instances that hosts the multi-model endpoint. Auto scaling works best when the models are similarly sized and homogenous, that is when they have similar inference latency and resource requirements.

In some cases, you might opt to reduce costs by choosing an instance type that can't hold all of the targeted models in memory at once. SageMaker dynamically unloads models when it runs out of memory to make room for a newly targeted model. For infrequently requested models, you are going to pay a price with the dynamic load latency. In cases with more stringent latency needs, you might opt for larger instance types or more instances. Investing time up front for proper performance testing and analysis will pay great dividends in successful production deployments.

You can use the `Average` statistic of the `ModelCacheHit` metric to monitor the ratio of requests where the model is already loaded. You can use the `SampleCount` statistic for the `ModelUnloadingTime` metric to monitor the number of unload requests sent to the container during a time period. If models are unloaded too frequently (an indicator of thrashing, where models are being unloaded and loaded again because there is insufficient cache space for the working set of models), consider using a larger instance type with more memory or increasing the number of instances behind the multi-model endpoint. For multi-model endpoints with multiple instances, be aware that a model might be loaded on more than 1 instance.

SageMaker multi-model endpoints fully supports Auto Scaling, which manages replicas of models to ensure models scale based on traffic patterns. We recommend that you configure your multi-model endpoint and the size of your instances by considering all of the above and also set up auto scaling for your endpoint. The invocation rates used to trigger an auto-scale event is based on the aggregate set of predictions across the full set of models served by the endpoint.

## Create a Multi-Model Endpoint

You can use Amazon SDK for Python (Boto) or Amazon SageMaker to create a multi-model endpoint.

### Topics

- [Create a Multi-Model Endpoint \(Console\) \(p. 1898\)](#)
- [Create a Multi-Model Endpoint \(Amazon SDK for Python \(Boto\)\) \(p. 1901\)](#)

## Create a Multi-Model Endpoint (Console)

**To create a multi-model endpoint (console)**

1. Open the Amazon SageMaker console at <https://console.amazonaws.cn/sagemaker/>.
2. Choose **Model**, and then from the **Inference** group, choose **Create model**.
3. For **Model name**, enter a name.
4. For **IAM role**, choose or create an IAM role that has the AmazonSageMakerFullAccess IAM policy attached.
5. In the **Container definition** section, for **Provide model artifacts and inference image options** choose **Use multiple models**.

The screenshot shows the 'Create model' page in the Amazon SageMaker console. At the top, there's a navigation bar with the Amazon logo, 'Services' dropdown, and 'Resource Groups'. Below that, a breadcrumb trail shows 'Amazon SageMaker > Models > Create model'. The main title 'Create model' is displayed prominently. A sub-section title 'Model settings' is visible. Under 'Model name', the value 'mml-test-model' is entered, with a note below stating 'Maximum of 63 alphanumeric characters. Can include your account in an Region.' Under 'IAM role', it says 'Amazon SageMaker requires permissions to call other services. Create a role that has the [AmazonSageMakerFullAccess](#) policy.' A specific role name 'AmazonSageMaker-ExecutionRole- XXXXX' is listed. At the bottom, there's a section titled 'Container definition 1'.

Services ▾ Resource Groups

Amazon SageMaker > Models > Create model

# Create model

To deploy a model to Amazon SageMaker, first upload inference code. See [Deploying a Model on Amazon SageMaker](#).

## Model settings

Model name

mml-test-model

Maximum of 63 alphanumeric characters. Can include your account in an Region.

IAM role

Amazon SageMaker requires permissions to call other services. Create a role that has the [AmazonSageMakerFullAccess](#) policy.

AmazonSageMaker-ExecutionRole- XXXXX

## Container definition 1

6. Choose **Create model**.
7. Deploy your multi-model endpoint as you would a single model endpoint. For instructions, see [Deploy the Model to SageMaker Hosting Services \(p. 63\)](#).

## Create a Multi-Model Endpoint (Amazon SDK for Python (Boto))

You create a multi-model endpoint using the Amazon SageMaker `create_model`, `create_endpoint_config`, and `create_endpoint` APIs just as you would create a single model endpoint, but with two changes. When defining the model container, you need to pass a new `Mode` parameter value, `MultiModel`. You also need to pass the `ModelDataUrl` field that specifies the prefix in Amazon S3 where the model artifacts are located, instead of the path to a single model artifact, as you would when deploying a single model.

For a sample notebook that uses SageMaker to deploy multiple XGBoost models to an endpoint, see [Multi-Model Endpoint XGBoost Sample Notebook](#).

The following procedure outlines the key steps used in that sample to create a multi-model endpoint.

### To deploy the model (Amazon SDK for Python (Boto 3))

1. Get a container with an image that supports deploying multi-model endpoints. For a list of built-in algorithms and framework containers that support multi-model endpoints, see [Supported Algorithms and Frameworks \(p. 1896\)](#). For this example, we use the [K-Nearest Neighbors \(k-NN\) Algorithm \(p. 1428\)](#) built-in algorithm. We call the [SageMaker Python SDK](#) utility function `image_uris.retrieve()` to get the address for the K-Nearest Neighbors built-in algorithm image.

```
import sagemaker
region = sagemaker_session.boto_region_name
image = sagemaker.image_uris.retrieve("knn", region=region)
container = { 'Image': image,
              'ModelDataUrl': 's3://my-bucket/path/to/artifacts/',
              'Mode': 'MultiModel'
            }
```

2. Get a Boto 3 SageMaker client and create the model that uses this container.

```
import boto3
sm_client = boto3.client('sagemaker')
response = sm_client.create_model(
    ModelName = 'my-multi-model-name',
    ExecutionRoleArn = role,
    Containers = [container])
```

3. (Optional) If you are using a serial inference pipeline, get the additional container(s) to include in the pipeline, and include it in the `Containers` argument of `CreateModel`:

```
preprocessor_container = { 'Image': '123456789012.dkr.ecr.us-
east-1.amazonaws.com/mypreprocessorimage:mytag'
}

multi_model_container = { 'Image': '763104351884.dkr.ecr.us-
east-1.amazonaws.com/myimage:mytag',
                         'ModelDataUrl': 's3://my-bucket/path/to/artifacts/',
                         'Mode': 'MultiModel'
}

response = sm_client.create_model(
    ModelName = 'my-multi-model-name',
```

```
ExecutionRoleArn = role,
Containers      = [preprocessor_container, multi_model_container])
```

4. (Optional) If your use case does not benefit from model caching, set the value of the ModelCacheSetting field of the MultiModelConfig parameter to Disabled, and include it in the Container argument of the call to `create_model`. The value of the ModelCacheSetting field is Enabled by default.

```
container = {
    'Image': image,
    'ModelDataURL': 's3://my-bucket/path/to/artifacts/',
    'Mode': 'MultiModel',
    'MultiModelConfig': {
        // Default value is 'Enabled'
        'ModelCacheSetting': 'Disabled'
    }
}

response = sm_client.create_model(
    ModelName      = 'my-multi-model-name',
    ExecutionRoleArn = role,
    Containers     = [container])
```

5. Configure the multi-model endpoint for the model. We recommend configuring your endpoints with at least two instances. This allows SageMaker to provide a highly available set of predictions across multiple Availability Zones for the models.

```
response = sm_client.create_endpoint_config(
    EndpointConfigName = 'my-epc',
    ProductionVariants=[{
        'InstanceType':           'ml.m4.xlarge',
        'InitialInstanceCount':  2,
        'InitialVariantWeight':  1,
        'ModelName':              'my-multi-model-name',
        'VariantName':            'AllTraffic'}])
```

#### Note

You can use only one multi-model-enabled endpoint in a serial inference pipeline.

6. Create the multi-model endpoint using the `EndpointName` and `EndpointConfigName` parameters.

```
response = sm_client.create_endpoint(
    EndpointName      = 'my-endpoint',
    EndpointConfigName = 'my-epc')
```

## Invoke a Multi-Model Endpoint

To invoke a multi-model endpoint, use the [invoke\\_endpoint](#) from the SageMaker Runtime just as you would invoke a single model endpoint, with one change. Pass a new `TargetModel` parameter that specifies which of the models at the endpoint to target. The SageMaker Runtime `InvokeEndpoint` request supports `X-Amzn-SageMaker-Target-Model` as a new header that takes the relative path of the model specified for invocation. The SageMaker system constructs the absolute path of the model by combining the prefix that is provided as part of the `CreateModel` API call with the relative path of the model.

The following example prediction request uses the [Amazon SDK for Python \(Boto 3\)](#) in the sample notebook.

```
response = runtime_sm_client.invoke_endpoint(
```

```
EndpointName = 'my-endpoint',
ContentType = 'text/csv',
TargetModel = 'Houston_TX.tar.gz',
Body = body)
```

The multi-model endpoint dynamically loads target models as needed. You can observe this when running the [MME Sample Notebook](#) as it iterates through random invocations against multiple target models hosted behind a single endpoint. The first request against a given model takes longer because the model has to be downloaded from Amazon Simple Storage Service (Amazon S3) and loaded into memory. (This is called a cold start.) Subsequent calls finish faster because there's no additional overhead after the model has loaded.

## Retry Requests on ModelNotReadyException Errors

The first time you call `invoke_endpoint` for a model, the model is downloaded from Amazon Simple Storage Service and loaded into the inference container. This makes the first call take longer to return. Subsequent calls to the same model finish faster, because the model is already loaded.

SageMaker returns a response for a call to `invoke_endpoint` within 60 seconds. Some models are too large to download within 60 seconds. If the model does not finish loading before the 60 second timeout limit, the request to `invoke_endpoint` returns with the error code `ModelNotReadyException`, and the model continues to download and load into the inference container for up to 360 seconds. If you get a `ModelNotReadyException` error code for an `invoke_endpoint` request, retry the request. By default, the Amazon SDKs for Python (Boto 3) (using [Legacy retry mode](#)) and Java retry `invoke_endpoint` requests that result in `ModelNotReadyException` errors. You can configure the retry strategy to continue retrying the request for up to 360 seconds. If you expect your model to take longer than 60 seconds to download and load into the container, set the SDK socket timeout to 70 seconds. For more information about configuring the retry strategy for Boto 3, see [Configuring a retry mode](#). The following code shows an example that configures the retry strategy to retry calls to `invoke_endpoint` for up to 180 seconds.

```
import boto3
from botocore.config import Config

# This example retry strategy sets the retry attempts to 2.
# With this setting, the request can attempt to download and/or load the model
# for upto 180 seconds: 1 orginal request (60 seconds) + 2 retries (120 seconds)
config = Config(
    read_timeout=70,
    retries={
        'max_attempts': 2 # This value can be adjusted to 5 to go up to the 360s max
    timeout
    }
)
runtime_sm_client = boto3.client('sagemaker-runtime', config=config)
```

## Add or Remove Models

You can deploy additional models to a multi-model endpoint and invoke them through that endpoint immediately. When adding a new model, you don't need to update or bring down the endpoint, so you avoid the cost of creating and running a separate endpoint for each new model.

SageMaker unloads unused models from the container when the instance is reaching memory capacity and more models need to be downloaded into the container. SageMaker also deletes unused model artifacts from the instance storage volume when the volume is reaching capacity and new models need to be downloaded. The first invocation to a newly added model takes longer because the endpoint takes time to download the model from S3 to the container's memory in instance hosting the endpoint

With the endpoint already running, copy a new set of model artifacts to the Amazon S3 location there you store your models.

```
# Add an AdditionalModel to the endpoint and exercise it
aws s3 cp AdditionalModel.tar.gz s3://my-bucket/path/to/artifacts/
```

**Important**

To update a model, proceed as you would when adding a new model. Use a new and unique name. Don't overwrite model artifacts in Amazon S3 because the old version of the model might still be loaded in the containers or on the storage volume of the instances on the endpoint. Invocations to the new model could then invoke the old version of the model.

Client applications can request predictions from the additional target model as soon as it is stored in S3.

```
response = runtime_sm_client.invoke_endpoint(
    EndpointName='endpoint_name',
    ContentType='text/csv',
    TargetModel='AdditionalModel.tar.gz',
    Body=body)
```

To delete a model from a multi-model endpoint, stop invoking the model from the clients and remove it from the S3 location where model artifacts are stored.

## Build Your Own Container with Multi Model Server

Custom Elastic Container Registry (ECR) images deployed in Amazon SageMaker are expected to adhere to the basic contract described in [Use Your Own Inference Code with Hosting Services \(p. 2167\)](#) that govern how SageMaker interacts with a Docker container that runs your own inference code. For a container to be capable of loading and serving multiple models concurrently, there are additional APIs and behaviors that must be followed. This additional contract includes new APIs to load, list, get, and unload models, and a different API to invoke models. There are also different behaviors for error scenarios that the APIs need to abide by. To indicate that the container complies with the additional requirements, you can add the following command to your Docker file:

```
LABEL com.amazonaws.sagemaker.capabilities.multi-models=true
```

SageMaker also injects an environment variable into the container

```
SAGEMAKER_MULTI_MODEL=true
```

If you are creating a multi-model endpoint for a serial inference pipeline, your Docker file must have the required labels for both multi-models and serial inference pipelines. For more information about serial information pipelines, see [Run Real-time Predictions with an Inference Pipeline \(p. 1921\)](#).

To help you implement these requirements for a custom container, two libraries are available:

- [Multi Model Server](#) is an open source framework for serving machine learning models that can be installed in containers to provide the front end that fulfills the requirements for the new multi-model endpoint container APIs. It provides the HTTP front end and model management capabilities required by multi-model endpoints to host multiple models within a single container, load models into and unload models out of the container dynamically, and performs inference on a specified loaded model. It also provides a pluggable backend that supports a pluggable custom backend handler where you can implement your own algorithm.
- [SageMaker Inference Toolkit](#) is a library that bootstraps Multi Model Server with a configuration and settings that make it compatible with SageMaker multi-model endpoints. It also allows you to tweak important performance parameters, such as the number of workers per model, depending on the needs of your scenario.

## Use the SageMaker Inference Toolkit

Currently, the only pre-built containers that support multi-model endpoints are the MXNet inference container and the PyTorch inference container. If you want to use any other framework or algorithm, you need to build a container. The easiest way to do this is to use the [SageMaker Inference Toolkit](#) to extend an existing pre-built container. The SageMaker inference toolkit is an implementation for the multi-model server (MMS) that creates endpoints that can be deployed in SageMaker. For a sample notebook that shows how to set up and deploy a custom container that supports multi-model endpoints in SageMaker, see the [Multi-Model Endpoint BYOC Sample Notebook](#).

### Note

The SageMaker inference toolkit supports only Python model handlers. If you want to implement your handler in any other language, you must build your own container that implements the additional multi-model endpoint APIs. For information, see [Contract for Custom Containers to Serve Multiple Models \(p. 1906\)](#).

### To extend a container by using the SageMaker inference toolkit

1. Create a model handler. MMS expects a model handler, which is a Python file that implements functions to pre-process, get predictions from the model, and process the output in a model handler. For an example of a model handler, see [model\\_handler.py](#) from the sample notebook.
2. Import the inference toolkit and use its `model_server.start_model_server` function to start MMS. The following example is from the `dockerd-entrypoint.py` file from the sample notebook. Notice that the call to `model_server.start_model_server` passes the model handler described in the previous step:

```
import subprocess
import sys
import shlex
import os
from retrying import retry
from subprocess import CalledProcessError
from sagemaker_inference import model_server

def _retry_if_error(exception):
    return isinstance(exception, CalledProcessError or OSError)

@retry(stop_max_delay=1000 * 50,
       retry_on_exception=_retry_if_error)
def _start_mms():
    # by default the number of workers per model is 1, but we can configure it through
    # the
    # environment variable below if desired.
    # os.environ['SAGEMAKER_MODEL_SERVER_WORKERS'] = '2'
    model_server.start_model_server(handler_service='/home/model-server/
model_handler.py:handle')

def main():
    if sys.argv[1] == 'serve':
        _start_mms()
    else:
        subprocess.check_call(shlex.split(' '.join(sys.argv[1:])))

    # prevent docker exit
    subprocess.call(['tail', '-f', '/dev/null'])

main()
```

3. In your Dockerfile, copy the model handler from the first step and specify the Python file from the previous step as the entrypoint in your Dockerfile. The following lines are from the [Dockerfile](#) used in the sample notebook:

```
# Copy the default custom service file to handle incoming data and inference requests
COPY model_handler.py /home/model-server/model_handler.py

# Define an entrypoint script for the docker image
ENTRYPOINT [ "python", "/usr/local/bin/dockerd-entrypoint.py" ]
```

4. Build and register your container. The following shell script from the sample notebook builds the container and uploads it to an Amazon Elastic Container Registry repository in your Amazon account:

```
%%sh

# The name of our algorithm
algorithm_name=demo-sagemaker-multimodel

cd container

account=$(aws sts get-caller-identity --query Account --output text)

# Get the region defined in the current configuration (default to us-west-2 if none
# defined)
region=$(aws configure get region)
region=${region:-us-west-2}

fullname="${account}.dkr.ecr.${region}.amazonaws.com/${algorithm_name}:latest"

# If the repository doesn't exist in ECR, create it.
aws ecr describe-repositories --repository-names "${algorithm_name}" > /dev/null 2>&1

if [ $? -ne 0 ]
then
    aws ecr create-repository --repository-name "${algorithm_name}" > /dev/null
fi

# Get the login command from ECR and execute it directly
$(aws ecr get-login --region ${region} --no-include-email)

# Build the docker image locally with the image name and then push it to ECR
# with the full name.

docker build -q -t ${algorithm_name} .
docker tag ${algorithm_name} ${fullname}

docker push ${fullname}
```

You can now use this container to deploy multi-model endpoints in SageMaker.

#### Topics

- [Contract for Custom Containers to Serve Multiple Models \(p. 1906\)](#)

## Contract for Custom Containers to Serve Multiple Models

To handle multiple models, your container must support a set of APIs that enable Amazon SageMaker to communicate with the container for loading, listing, getting, and unloading models as required. The `model_name` is used in the new set of APIs as the key input parameter. The customer container is expected to keep track of the loaded models using `model_name` as the mapping key. Also, the `model_name` is an opaque identifier and is not necessarily the value of the `TargetModel` parameter passed into the `InvokeEndpoint` API. The original `TargetModel` value in the `InvokeEndpoint`

request is passed to container in the APIs as a `X-Amzn-SageMaker-Target-Model` header that can be used for logging purposes.

### Topics

- [Load Model API \(p. 1907\)](#)
- [List Model API \(p. 1907\)](#)
- [Get Model API \(p. 1908\)](#)
- [Unload Model API \(p. 1908\)](#)
- [Invoke Model API \(p. 1908\)](#)

## Load Model API

Instructs the container to load a particular model present in the `url` field of the body into the memory of the customer container and to keep track of it with the assigned `model_name`. After a model is loaded, the container should be ready to serve inference requests using this `model_name`.

```
POST /models HTTP/1.1
Content-Type: application/json
Accept: application/json

{
    "model_name" : "{model_name}",
    "url" : "/opt/ml/models/{model_name}/model",
}
```

### Note

If `model_name` is already loaded, this API should return 409. Any time a model cannot be loaded due to lack of memory or to any other resource, this API should return a 507 HTTP status code to SageMaker, which then initiates unloading unused models to reclaim.

## List Model API

Returns the list of models loaded into the memory of the customer container.

```
GET /models HTTP/1.1
Accept: application/json

Response =
{
    "models": [
        {
            "modelName" : "{model_name}",
            "modelUrl" : "/opt/ml/models/{model_name}/model",
        },
        {
            "modelName" : "{model_name}",
            "modelUrl" : "/opt/ml/models/{model_name}/model",
        },
        ...
    ]
}
```

This API also supports pagination.

```
GET /models HTTP/1.1
Accept: application/json

Response =
```

```
{
  "models": [
    {
      "modelName" : "{model_name}",
      "modelUrl" : "/opt/ml/models/{model_name}/model",
    },
    {
      "modelName" : "{model_name}",
      "modelUrl" : "/opt/ml/models/{model_name}/model",
    },
    ...
  ]
}
```

SageMaker can initially call the List Models API without providing a value for `next_page_token`. If a `nextPageToken` field is returned as part of the response, it will be provided as the value for `next_page_token` in a subsequent List Models call. If a `nextPageToken` is not returned, it means that there are no more models to return.

## Get Model API

This is a simple read API on the `model_name` entity.

```
GET /models/{model_name} HTTP/1.1
Accept: application/json

{
  "modelName" : "{model_name}",
  "modelUrl" : "/opt/ml/models/{model_name}/model",
}
```

### Note

If `model_name` is not loaded, this API should return 404.

## Unload Model API

Instructs the SageMaker platform to instruct the customer container to unload a model from memory. This initiates the eviction of a candidate model as determined by the platform when starting the process of loading a new model. The resources provisioned to `model_name` should be reclaimed by the container when this API returns a response.

```
DELETE /models/{model_name}
```

### Note

If `model_name` is not loaded, this API should return 404.

## Invoke Model API

Makes a prediction request from the particular `model_name` supplied. The SageMaker Runtime `InvokeEndpoint` request supports `X-Amzn-SageMaker-Target-Model` as a new header that takes the relative path of the model specified for invocation. The SageMaker system constructs the absolute path of the model by combining the prefix that is provided as part of the `CreateModel` API call with the relative path of the model.

```
POST /models/{model_name}/invoke HTTP/1.1
Content-Type: ContentType
Accept: Accept
X-Amzn-SageMaker-Custom-Attributes: CustomAttributes
X-Amzn-SageMaker-Target-Model: [relativePath]/[artifactName].tar.gz
```

**Note**

If `model_name` is not loaded, this API should return 404.

## Multi-Model Endpoint Security

Models and data in a multi-model endpoint are co-located on instance storage volume and in container memory. All instances for Amazon SageMaker endpoints run on a single tenant container that you own. Only your models can run on your multi-model endpoint. It's your responsibility to manage the mapping of requests to models and to provide access for users to the correct target models. SageMaker uses [IAM roles](#) to provide IAM identity-based policies that you use to specify allowed or denied actions and resources and the conditions under which actions are allowed or denied.

By default, an IAM principal with `InvokeEndpoint` permissions on a multi-model endpoint can invoke any model at the address of the S3 prefix defined in the `CreateModel` operation, provided that the IAM Execution Role defined in operation has permissions to download the model. If you need to restrict `InvokeEndpoint` access to a limited set of models in S3, you can do one of the following:

- Restrict `InvokeEndpoint` calls to specific models hosted at the endpoint by using the `sagemaker:TargetModel` IAM condition key. For example, the following policy allows `InvokeEndpoint` requests only when the value of the `TargetModel` field matches one of the specified regular expressions:

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Action": [  
                "sagemaker:InvokeEndpoint"  
            ],  
            "Effect": "Allow",  
            "Resource":  
                "arn:aws:sagemaker:region:account-id:endpoint/endpoint_name",  
            "Condition": {  
                // TargetModel provided must be from this set of values  
                "StringLike": {  
                    "sagemaker:TargetModel": ["company_a/*", "common/*"]  
                }  
            }  
        },  
    ]  
}
```

For information about SageMaker condition keys, see [Condition Keys for Amazon SageMaker](#) in the [Amazon Identity and Access Management User Guide](#).

- Create multi-model endpoints with more restrictive S3 prefixes.

For more information about how SageMaker uses roles to manage access to endpoints and perform operations on your behalf, see [SageMaker Roles \(p. 2447\)](#). Your customers might also have certain data isolation requirements dictated by their own compliance requirements that can be satisfied using IAM identities.

## CloudWatch Metrics for Multi-Model Endpoint Deployments

Amazon SageMaker provides metrics for endpoints so you can monitor the cache hit rate, the number of models loaded, and the model wait times for loading, downloading, and uploading at a multi-

model endpoint. For information, see **Multi-Model Endpoint Model Loading Metrics** and **Multi-Model Endpoint Model Instance Metrics** in [Monitor Amazon SageMaker with Amazon CloudWatch \(p. 2523\)](#). Per-model metrics aren't supported.

## Deploy multi-container endpoints

SageMaker multi-container endpoints enable customers to deploy multiple containers to deploy different models on a SageMaker endpoint. The containers can be run in a sequence as an inference pipeline, or each container can be accessed individually by using direct invocation to improve endpoint utilization and optimize costs.

For information about invoking the containers in a multi-container endpoint in sequence, see [Deploy an Inference Pipeline \(p. 1917\)](#).

For information about invoking a specific container in a multi-container endpoint, see [Use a multi-container endpoint with direct invocation \(p. 1911\)](#)

### Topics

- [Create a multi-container endpoint \(Boto 3\) \(p. 1910\)](#)
- [Update a multi-container endpoint \(p. 1911\)](#)
- [Delete a multi-container endpoint \(p. 1911\)](#)
- [Use a multi-container endpoint with direct invocation \(p. 1911\)](#)
- [Deploy an Inference Pipeline \(p. 1917\)](#)

## Create a multi-container endpoint (Boto 3)

Create a Multi-container endpoint by calling `create_model`, `create_endpoint_config`, and `create_endpoint` APIs as you would to create any other endpoints. You can run these containers sequentially as an inference pipeline, or run each individual container by using direct invocation. Multi-container endpoints have the following requirements when you call `create_model`:

- Use the `Containers` parameter instead of `PrimaryContainer`, and include more than one container in the `Containers` parameter.
- The `ContainerHostname` parameter is required for each container in a multi-container endpoint with direct invocation.
- Set the `Mode` parameter of the `InferenceExecutionConfig` field to `Direct` for direct invocation of each container, or `Serial` to use containers as an inference pipeline. The default mode is `Serial`.

### Note

Currently there is a limit of up to 5 containers supported on a multi-container endpoint.

The following example creates a multi-container model for direct invocation.

1. Create container elements and `InferenceExecutionConfig` with direct invocation.

```
container1 = { 'Image':           '123456789012.dkr.ecr.us-east-1.amazonaws.com/'  
              'myimage1:mytag',  
              'ContainerHostname': 'firstContainer'}  
  
container2 = { 'Image':           '123456789012.dkr.ecr.us-east-1.amazonaws.com/'  
              'myimage2:mytag',  
              'ContainerHostname': 'secondContainer'  
            }  
inferenceExecutionConfig = {'Mode': 'Direct'}
```

}

2. Create the model with the container elements and set the `InferenceExecutionConfig` field.

```
import boto3
sm_client = boto3.Session().client('sagemaker')

response = sm_client.create_model(
    ModelName      = 'my-direct-mode-model-name',
    InferenceExecutionConfig = inferenceExecutionConfig,
    ExecutionRoleArn = role,
    Containers     = [container1, container2])
```

To create an endpoint, you would then call `create_endpoint_config` and `create_endpoint` as you would to create any other endpoint.

## Update a multi-container endpoint

To update a multi-container endpoint, complete the following steps.

1. Call `create_model` to create a new model with a new value for the `Mode` parameter in the `InferenceExecutionConfig` field.
2. Call `create_endpoint_config` to create a new endpoint config with a different name by using the new model you created in the previous step.
3. Call `update_endpoint` to update the endpoint with the new endpoint config you created in the previous step.

## Delete a multi-container endpoint

To delete an endpoint, call `delete_endpoint`, and provide the name of the endpoint you want to delete as the `EndpointName` parameter.

## Use a multi-container endpoint with direct invocation

SageMaker multi-container endpoints enable customers to deploy multiple containers to deploy different models on a SageMaker endpoint. You can host up to 5 different inference containers on a single endpoint. By using direct invocation, you can send a request to a specific inference container hosted on a multi-container endpoint.

### Topics

- [Invoke a multi-container endpoint with direct invocation \(p. 1911\)](#)
- [Security with multi-container endpoints with direct invocation \(p. 1912\)](#)
- [Metrics for multi-container endpoints with direct invocation \(p. 1913\)](#)
- [Autoscale multi-container endpoints \(p. 1916\)](#)
- [Troubleshoot multi-container endpoints \(p. 1916\)](#)

## Invoke a multi-container endpoint with direct invocation

To invoke a multi-container endpoint with direct invocation, call `invoke_endpoint` as you would invoke any other endpoint, and specify which container you want to invoke by using the `TargetContainerHostname` parameter.

The following example directly invokes the `secondContainer` of a multi-container endpoint to get a prediction.

```
import boto3
runtime_sm_client = boto3.Session().client('sagemaker-runtime')

response = runtime_sm_client.invoke_endpoint(
    EndpointName ='my-endpoint',
    ContentType = 'text/csv',
    TargetContainerHostname='secondContainer',
    Body = body)
```

For each direct invocation request to a multi-container endpoint, only the container with the `TargetContainerHostname` processes the invocation request. You will get validation errors if you do any of the following:

- Specify a `TargetContainerHostname` that does not exist in the endpoint
- Do not specify a value for `TargetContainerHostname` in a request to an endpoint configured for direct invocation
- Specify a value for `TargetContainerHostname` in a request to an endpoint that is not configured for direct invocation.

## Security with multi-container endpoints with direct invocation

For multi-container endpoints with direct invocation, there are multiple containers hosted in a single instance by sharing memory and a storage volume. It's your responsibility to use secure containers, maintain the correct mapping of requests to target containers, and provide users with the correct access to target containers. SageMaker uses IAM roles to provide IAM identity-based policies that you use to specify whether access to a resource is allowed or denied to that role, and under what conditions. For information about IAM roles, see [IAM roles in the Amazon Identity and Access Management User Guide](#). For information about identity-based policies, see [Identity-based policies and resource-based policies](#).

By default, an IAM principal with `InvokeEndpoint` permissions on a multi-container endpoint with direct invocation can invoke any container inside the endpoint with the endpoint name that you specify when you call `invoke_endpoint`. If you need to restrict `invoke_endpoint` access to a limited set of containers inside a multi-container endpoint, use the `sagemaker:TargetContainerHostname` IAM condition key. The following policies show how to limit calls to specific containers within an endpoint.

The following policy allows `invoke_endpoint` requests only when the value of the `TargetContainerHostname` field matches one of the specified regular expressions.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Action": [
                "sagemaker:InvokeEndpoint"
            ],
            "Effect": "Allow",
            "Resource": "arn:aws:sagemaker:region:account-id:endpoint/endpoint_name",
            "Condition": {
                "StringLike": {
                    "sagemaker:TargetContainerHostname": ["customIps*", "common*"]
                }
            }
        ]
    ]
}
```

The following policy denies `invoke_endpoint` requests when the value of the `TargetContainerHostname` field matches one of the specified regular expressions in the `Deny` statement.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Action": [
                "sagemaker:InvokeEndpoint"
            ],
            "Effect": "Allow",
            "Resource": "arn:aws:sagemaker:region:account-id:endpoint/endpoint_name",
            "Condition": {
                "StringLike": {
                    "sagemaker:TargetContainerHostname": ["*"]
                }
            }
        },
        {
            "Action": [
                "sagemaker:InvokeEndpoint"
            ],
            "Effect": "Deny",
            "Resource": "arn:aws:sagemaker:region:account-id:endpoint/endpoint_name",
            "Condition": {
                "StringLike": {
                    "sagemaker:TargetContainerHostname": ["special*"]
                }
            }
        }
    ]
}
```

For information about SageMaker condition keys, see [Condition Keys for SageMaker](#) in the *Amazon Identity and Access Management User Guide*.

## Metrics for multi-container endpoints with direct invocation

In addition to the endpoint metrics that are listed in [Monitor Amazon SageMaker with Amazon CloudWatch \(p. 2523\)](#), SageMaker also provides per-container metrics.

Per-container metrics for multi-container endpoints with direct invocation are located in CloudWatch and categorized into two namespaces: `AWS/SageMaker` and `aws/sagemaker/Endpoints`. The `AWS/SageMaker` namespace includes invocation-related metrics, and the `aws/sagemaker/Endpoints` namespace includes memory and CPU utilization metrics.

The following table lists the per-container metrics for multi-container endpoints with direct invocation. All the metrics use the `[EndpointName, VariantName, ContainerName]` dimension, which filters metrics at a specific endpoint, for a specific variant and corresponding to a specific container. These metrics share the same metric names as in those for inference pipelines, but at a per-container level `[EndpointName, VariantName, ContainerName]`.

Metric Name	Description	Dimension	NameSpace
<b>Invocations</b>	The number of <code>InvokeEndpoint</code> requests sent to a container inside an	<code>EndpointName,</code> <code>VariantName,</code> <code>ContainerName</code>	<code>AWS/SageMaker</code>

	endpoint. To get the total number of requests sent to that container, use the Sum statistic. Units: None Valid statistics: Sum, Sample Count		
Invocation4XX Errors	The number of InvokeEndpoint requests that the model returned a 4xx HTTP response code for on a specific container. For each 4xx response, SageMaker sends a 1. Units: None Valid statistics: Average, Sum	EndpointName, VariantName, ContainerName	AWS/SageMaker
Invocation5XX Errors	The number of InvokeEndpoint requests that the model returned a 5xx HTTP response code for on a specific container. For each 5xx response, SageMaker sends a 1. Units: None Valid statistics: Average, Sum	EndpointName, VariantName, ContainerName	AWS/SageMaker
ContainerLatency	The time it took for the target container to respond as viewed from SageMaker. ContainerLatency includes the time it took to send the request, to fetch the response from the model's container, and to complete inference in the container. Units: Microseconds Valid statistics: Average, Sum, Min, Max, Sample Count	EndpointName, VariantName, ContainerName	AWS/SageMaker

OverheadLatency	The time added to the time taken to respond to a client request by SageMaker for overhead. OverheadLatency is measured from the time that SageMaker receives the request until it returns a response to the client, minus theModelLatency. Overhead latency can vary depending on request and response payload sizes, request frequency, and authentication or authorization of the request, among other factors. Units: Microseconds Valid statistics: Average, Sum, Min, Max, `Sample Count`	EndpointName, VariantName, ContainerName	AWS/SageMaker
CPUUtilization	The percentage of CPU units that are used by each container running on an instance. The value ranges from 0% to 100%, and is multiplied by the number of CPUs. For example, if there are four CPUs, CPUUtilization can range from 0% to 400%. For endpoints with direct invocation, the number of CPUUtilization metrics equals the number of containers in that endpoint. Units: Percent	EndpointName, VariantName, ContainerName	aws/sagemaker/Endpoints

<code>MemoryUtilizaton</code>	The percentage of memory that is used by each container running on an instance. This value ranges from 0% to 100%. Similar as <code>CPUUtilization</code> , in endpoints with direct invocation, the number of <code>MemoryUtilization</code> metrics equals the number of containers in that endpoint. Units: Percent	<code>EndpointName</code> , <code>VariantName</code> , <code>ContainerName</code>	<code>aws/sagemaker/Endpoints</code>
-------------------------------	--	---	--------------------------------------

All the metrics in the previous table are specific to multi-container endpoints with direct invocation. Besides these special per-container metrics, there are also metrics at the variant level with dimension [`EndpointName`, `VariantName`] for all the metrics in the table expect `ContainerLatency`.

## Autoscale multi-container endpoints

If you want to configure automatic scaling for a multi-container endpoint using the `InvocationsPerInstance` metric, we recommend that the model in each container exhibits similar CPU utilization and latency on each inference request. This is recommended because if traffic to the multi-container endpoint shifts from a high CPU utilization model to a low CPU utilization model, but the overall call volume remains the same, the endpoint does not scale out and there may not be enough instances to handle all the requests to the high CPU utilization model. For information about automatically scaling endpoints, see [Automatically Scale Amazon SageMaker Models \(p. 1931\)](#).

## Troubleshoot multi-container endpoints

The following sections can help you troubleshoot errors with multi-container endpoints.

### Ping Health Check Errors

With multiple containers, endpoint memory and CPU are under higher pressure during endpoint creation. Specifically, the `MemoryUtilization` and `CPUUtilization` metrics are higher than for single-container endpoints, because utilization pressure is proportional to the number of containers. Because of this, we recommend that you choose instance types with enough memory and CPU to ensure that there is enough memory on the instance to have all the models loaded (the same guidance applies to deploying an inference pipeline). Otherwise, your endpoint creation might fail with an error such as `XXX did not pass the ping health check`.

### Missing accept-bind-to-port=true Docker label

The containers in a multi-container endpoints listen on the port specified in the `SAGEMAKER_BIND_TO_PORT` environment variable instead of port 8080. When a container runs in a multi-container endpoint, SageMaker automatically provides this environment variable to the container. If this environment variable isn't present, containers default to using port 8080. To indicate that your container complies with this requirement, use the following command to add a label to your Dockerfile:

```
LABEL com.amazonaws.sagemaker.capabilities.accept-bind-to-port=true
```

Otherwise, You will see an error message such as `Your Ecr Image XXX does not contain required com.amazonaws.sagemaker.capabilities.accept-bind-to-port=true Docker label(s).`

If your container needs to listen on a second port, choose a port in the range specified by the `SAGEMAKER_SAFE_PORT_RANGE` environment variable. Specify the value as an inclusive range in the format `XXXX-YYYY`, where XXXX and YYYY are multi-digit integers. SageMaker provides this value automatically when you run the container in a multi-container endpoint.

## Deploy an Inference Pipeline

An *inference pipeline* is a Amazon SageMaker model that is composed of a linear sequence of two to five containers that process requests for inferences on data. You use an inference pipeline to define and deploy any combination of pretrained SageMaker built-in algorithms and your own custom algorithms packaged in Docker containers. You can use an inference pipeline to combine preprocessing, predictions, and post-processing data science tasks. Inference pipelines are fully managed.

You can add SageMaker Spark ML Serving and scikit-learn containers that reuse the data transformers developed for training models. The entire assembled inference pipeline can be considered as a SageMaker model that you can use to make either real-time predictions or to process batch transforms directly without any external preprocessing.

Within an inference pipeline model, SageMaker handles invocations as a sequence of HTTP requests. The first container in the pipeline handles the initial request, then the intermediate response is sent as a request to the second container, and so on, for each container in the pipeline. SageMaker returns the final response to the client.

When you deploy the pipeline model, SageMaker installs and runs all of the containers on each Amazon Elastic Compute Cloud (Amazon EC2) instance in the endpoint or transform job. Feature processing and inferences run with low latency because the containers are co-located on the same EC2 instances. You define the containers for a pipeline model using the [CreateModel](#) operation or from the console. Instead of setting one `PrimaryContainer`, you use the `Containers` parameter. to set the containers that make up the pipeline You also specify the order in which the containers are executed.

A pipeline model is immutable, but you can update an inference pipeline by deploying a new one using the [UpdateEndpoint](#) operation. This modularity supports greater flexibility during experimentation.

There are no additional costs for using this feature. You pay only for the instances running on an endpoint.

## Sample Notebooks for Inference Pipelines

For a sample notebook that uploads and processes a dataset, trains a model, and builds a pipeline model, see the [Inference Pipelines with Spark ML and XGBoost on Abalone](#) notebook. This notebook shows how you can build your machine learning pipeline by using Spark feature Transformers and the

SageMaker XGBoost algorithm. After training the model, the sample shows how to deploy the pipeline (feature Transformer and XGBoost) for real-time predictions and also performs a batch transform job using the same pipeline.

For an example that shows how to do both pre-processing and post-processing by using an inference pipeline, see [Deploy Apache Spark pre-processing and post-processing with XGBoost for real-time prediction requests in Amazon SageMaker using Inference Pipelines](#)

For more examples that show how to create and deploy inference pipelines, see the [Inference Pipelines with SparkML and BlazingText on DBpedia](#) and [Training using SparkML on EMR and hosting on SageMaker](#) sample notebooks. For instructions on creating and accessing Jupyter notebook instances that you can use to run the example in SageMaker, see [Use Amazon SageMaker Notebook Instances \(p. 120\)](#).

To see a list of all the SageMaker samples, after creating and opening a notebook instance, choose the **SageMaker Examples** tab. There are three inference pipeline notebooks. The first two inference pipeline notebooks just described are located in the advanced\_functionality folder and the third notebook is in the sagemaker-python-sdk folder. To open a notebook, choose its **Use** tab, then choose **Create copy**.

## Feature Processing with Spark ML and Scikit-learn

Before training a model with either Amazon SageMaker built-in algorithms or custom algorithms, you can use Spark and scikit-learn preprocessors to transform your data and engineer features.

### Feature Processing with Spark ML

You can run Spark ML jobs with [Amazon Glue](#), a serverless ETL (extract, transform, load) service, from your SageMaker notebook. You can also connect to existing EMR clusters to run Spark ML jobs with [Amazon EMR](#). To do this, you need an Amazon Identity and Access Management (IAM) role that grants permission for making calls from your SageMaker notebook to Amazon Glue.

#### Note

To see which Python and Spark versions Amazon Glue supports, refer to [Amazon Glue Release Notes](#).

After engineering features, you package and serialize Spark ML jobs with MLeap into MLeap containers that you can add to an inference pipeline. You don't need to use externally managed Spark clusters. With this approach, you can seamlessly scale from a sample of rows to terabytes of data. The same transformers work for both training and inference, so you don't need to duplicate preprocessing and feature engineering logic or develop a one-time solution to make the models persist. With inference pipelines, you don't need to maintain outside infrastructure, and you can make predictions directly from data inputs.

When you run a Spark ML job on Amazon Glue, a Spark ML pipeline is serialized into [MLeap](#) format. Then, you can use the job with the [SparkML Model Serving Container](#) in a SageMaker Inference Pipeline. [MLeap](#) is a serialization format and execution engine for machine learning pipelines. It supports Spark, Scikit-learn, and TensorFlow for training pipelines and exporting them to a serialized pipeline called an MLeap Bundle. You can deserialize Bundles back into Spark for batch-mode scoring or into the MLeap runtime to power real-time API services.

### Feature Processing with Sci-kit Learn

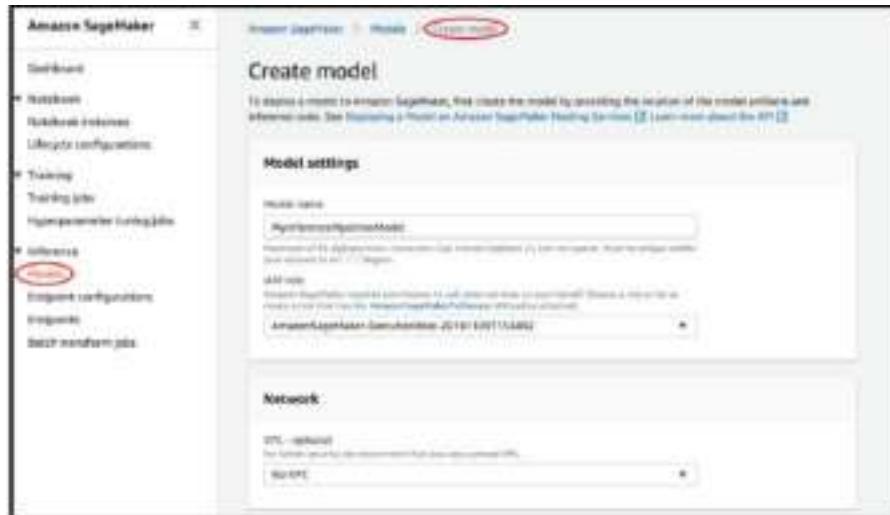

You can run and package scikit-learn jobs into containers directly in Amazon SageMaker. For an example of Python code for building a scikit-learn featurizer model that trains on [Fisher's Iris flower data set](#) and predicts the species of Iris based on morphological measurements, see [IRIS Training and Prediction with Sagemaker Scikit-learn](#).

## Create a Pipeline Model

To create a pipeline model that can be deployed to an endpoint or used for a batch transform job, use the Amazon SageMaker console or the `CreateModel` operation.

### To create an inference pipeline (console)

1. Open the Amazon SageMaker console at <https://console.amazonaws.cn/sagemaker/>.
2. Choose **Models**, and then choose **Create models** from the **Inference** group.
3. On the **Create model** page, provide a model name, choose an IAM role, and, if you want to use a private VPC, specify VPC values.

4. To add information about the containers in the inference pipeline, choose **Add container**, then choose **Next**.
5. Complete the fields for each container in the order that you want to execute them, up to the maximum of five. Complete the **Container input options**, **Location of inference code image**, and, optionally, **Location of model artifacts**, **Container host name**, and **Environmental variables** fields.

**Container definition 1**

\* Container input options

Provide model artifacts and inference image.

\* Provide model artifacts and inference image

Location of inference code image

The required code when my inference code image is served in Amazon ECR.

Location of model artifacts - optional

The URL for the S3 location where model artifacts are stored.

The path must point to a single zip component for inference image artifacts.

Container host name - optional

The DNS host name for the container.

Metadata of ET attachments (Resource, Data, Model, Pipeline, Job) is saved within your account from AWS Regions.

\* Environment variables - optional

Key	Value	Remove
key1	value1	<input type="button" value="Remove"/>
key2	value2	<input type="button" value="Remove"/>

Add environment variable

**Container definition 2 - optional**

\* Container input options

Provide model artifacts and inference image.

\* Provide model artifacts and inference image

Location of inference code image

The required code when my inference code image is served in Amazon ECR.

Location of model artifacts - optional

The URL for the S3 location where model artifacts are stored.

The path must point to a single zip component for inference image artifacts.

Container host name - optional

The DNS host name for the container.

Metadata of ET attachments (Resource, Data, Model, Pipeline, Job) is saved within your account from AWS Regions.

\* Environment variables - optional

Key	Value	Remove
		<input type="button" value="Remove"/>

Add environment variable

**Container definition 3 - optional**

\* Container input options

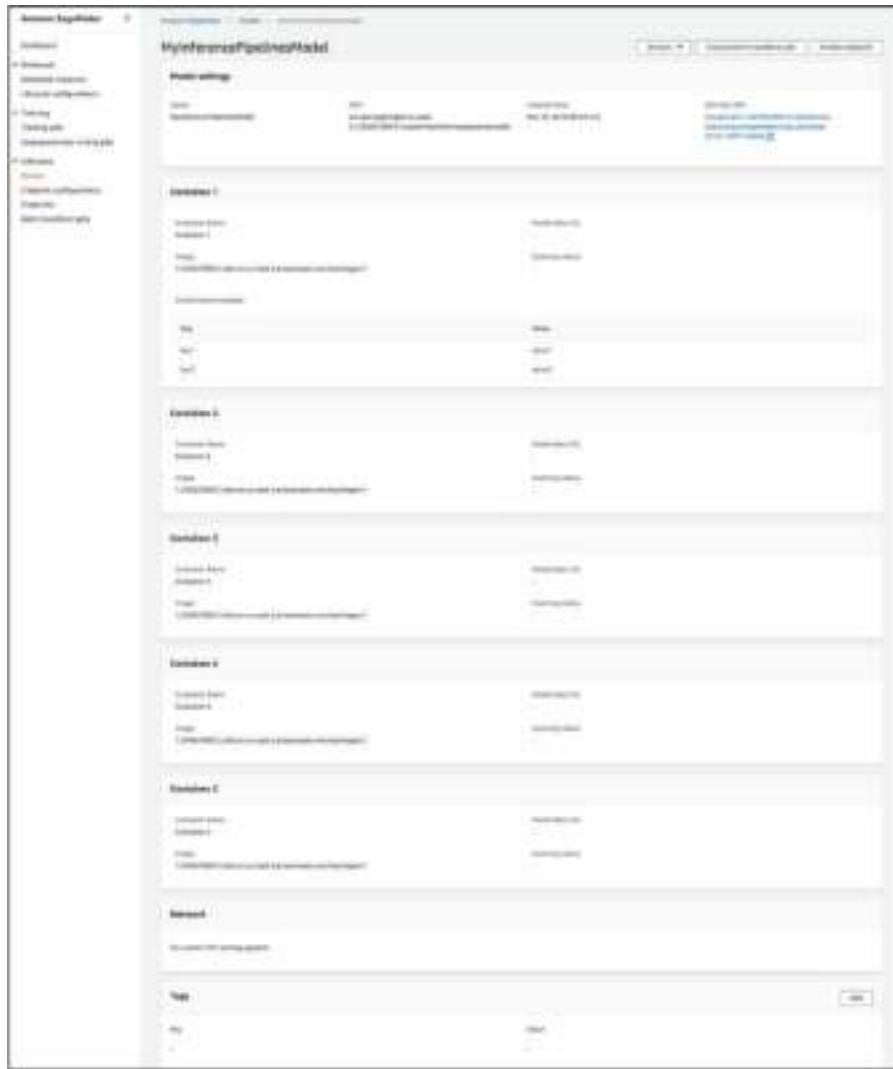

Provide model artifacts and inference image.

\* Provide model artifacts and inference image

Location of inference code image

The required code when my inference code image is served in Amazon ECR.

The **MyInferencePipelineModel** page summarizes the settings for the containers that provide input for the model. If you provided the environment variables in a corresponding container definition, SageMaker shows them in the **Environment variables** field.

## Run Real-time Predictions with an Inference Pipeline

You can use trained models in an inference pipeline to make real-time predictions directly without performing external preprocessing. When you configure the pipeline, you can choose to use the built-in feature transformers already available in Amazon SageMaker. Or, you can implement your own transformation logic using just a few lines of scikit-learn or Spark code.

[MLeap](#), a serialization format and execution engine for machine learning pipelines, supports Spark, scikit-learn, and TensorFlow for training pipelines and exporting them to a serialized pipeline called an MLeap Bundle. You can deserialize Bundles back into Spark for batch-mode scoring or into the MLeap runtime to power real-time API services.

The containers in a pipeline listen on the port specified in the `SAGEMAKER_BIND_TO_PORT` environment variable (instead of 8080). When running in an inference pipeline, SageMaker automatically provides this environment variable to containers. If this environment variable isn't present, containers default to using

port 8080. To indicate that your container complies with this requirement, use the following command to add a label to your Dockerfile:

```
LABEL com.amazonaws.sagemaker.capabilities.accept-bind-to-port=true
```

If your container needs to listen on a second port, choose a port in the range specified by the `SAGEMAKER_SAFE_PORT_RANGE` environment variable. Specify the value as an inclusive range in the format "`XXXX-YYYY`", where `XXXX` and `YYYY` are multi-digit integers. SageMaker provides this value automatically when you run the container in a multicontainer pipeline.

**Note**

To use custom Docker images in a pipeline that includes [SageMaker built-in algorithms](#), you need an [Amazon Elastic Container Registry \(Amazon ECR\) policy](#). Your Amazon ECR repository must grant SageMaker permission to pull the image. For more information, see [Troubleshoot Amazon ECR Permissions for Inference Pipelines \(p. 1929\)](#).

## Create and Deploy an Inference Pipeline Endpoint

The following code creates and deploys a real-time inference pipeline model with SparkML and XGBoost models in series using the SageMaker SDK.

```
from sagemaker.model import Model
from sagemaker.pipeline_model import PipelineModel
from sagemaker.sparkml.model import SparkMLModel

sparkml_data = 's3://{{}/{}}'.format(s3_model_bucket, s3_model_key_prefix, 'model.tar.gz')
sparkml_model = SparkMLModel(model_data=sparkml_data)
xgb_model = Model(model_data=xgb_model.model_data, image=training_image)

model_name = 'serial-inference-' + timestamp_prefix
endpoint_name = 'serial-inference-ep-' + timestamp_prefix
sm_model = PipelineModel(name=model_name, role=role, models=[sparkml_model, xgb_model])
sm_model.deploy(initial_instance_count=1, instance_type='ml.c4.xlarge',
    endpoint_name=endpoint_name)
```

## Request Real-Time Inference from an Inference Pipeline Endpoint

The following example shows how to make real-time predictions by calling an inference endpoint and passing a request payload in JSON format:

```
import sagemaker
from sagemaker.predictor import json_serializer, json_deserializer, Predictor

payload = {
    "input": [
        {
            "name": "Pclass",
            "type": "float",
            "val": "1.0"
        },
        {
            "name": "Embarked",
            "type": "string",
            "val": "Q"
        },
        {
            "name": "Age",
            "type": "double",
            "val": "48.0"
        }
    ]
}
```

```

        "name": "Fare",
        "type": "double",
        "val": "100.67"
    },
    {
        "name": "SibSp",
        "type": "double",
        "val": "1.0"
    },
    {
        "name": "Sex",
        "type": "string",
        "val": "male"
    }
],
"output": [
    {
        "name": "features",
        "type": "double",
        "struct": "vector"
    }
]
}

predictor = Predictor(endpoint=endpoint_name, sagemaker_session=sagemaker.Session(),
    serializer=json_serializer,
    content_type='text/csv', accept='application/json'

print(predictor.predict(payload))

```

The response you get from `predictor.predict(payload)` is the model's inference result.

### Realtime inference pipeline example

You can run this [example notebook using the SKLearn predictor](#) that shows how to deploy an endpoint, run an inference request, then deserialize the response. Find this notebook and more examples in the [Amazon SageMaker example GitHub repository](#).

## Run Batch Transforms with Inference Pipelines

To get inferences on an entire dataset you run a batch transform on a trained model. To run inferences on a full dataset, you can use the same inference pipeline model created and deployed to an endpoint for real-time processing in a batch transform job. To run a batch transform job in a pipeline, you download the input data from Amazon S3 and send it in one or more HTTP requests to the inference pipeline model. For an example that shows how to prepare data for a batch transform, see the "Preparing Data for Batch Transform" section of the [ML Pipeline with SparkML and XGBoost - Training and Inference sample notebook](#). For information about Amazon SageMaker batch transforms, see [Get Inferences for an Entire Dataset with Batch Transform \(p. 13\)](#).

#### Note

To use custom Docker images in a pipeline that includes [Amazon SageMaker built-in algorithms](#), you need an [Amazon Elastic Container Registry \(ECR\) policy](#). Your Amazon ECR repository must grant SageMaker permission to pull the image. For more information, see [Troubleshoot Amazon ECR Permissions for Inference Pipelines \(p. 1929\)](#).

The following example shows how to run a transform job using the [Amazon SageMaker Python SDK](#). In this example, `model1_name` is the inference pipeline that combines SparkML and XGBoost models (created in previous examples). The Amazon S3 location specified by `input_data_path` contains the input data, in CSV format, to be downloaded and sent to the Spark ML model. After the transform job has finished, the Amazon S3 location specified by `output_data_path` contains the output data returned by the XGBoost model in CSV format.

```

import sagemaker
input_data_path = 's3://{}//{}//{}'.format(default_bucket, 'key', 'file_name')

```

```

output_data_path = 's3://{}{}'.format(default_bucket, 'key')
transform_job = sagemaker.transformer.Transformer(
    model_name = model_name,
    instance_count = 1,
    instance_type = 'ml.m4.xlarge',
    strategy = 'SingleRecord',
    assemble_with = 'Line',
    output_path = output_data_path,
    base_transform_job_name='inference-pipelines-batch',
    sagemaker_session=sagemaker.Session(),
    accept = CONTENT_TYPE_CSV)
transform_job.transform(data = input_data_path,
                       content_type = CONTENT_TYPE_CSV,
                       split_type = 'Line')

```

## Inference Pipeline Logs and Metrics

Monitoring is important for maintaining the reliability, availability, and performance of Amazon SageMaker resources. To monitor and troubleshoot inference pipeline performance, use Amazon CloudWatch logs and error messages. For information about the monitoring tools that SageMaker provides, see [Monitor Amazon SageMaker \(p. 2523\)](#).

### Use Metrics to Monitor Multi-container Models

To monitor the multi-container models in Inference Pipelines, use Amazon CloudWatch. CloudWatch collects raw data and processes it into readable, near real-time metrics. SageMaker training jobs and endpoints write CloudWatch metrics and logs in the AWS/SageMaker namespace.

The following tables list the metrics and dimensions for the following:

- Endpoint invocations
- Training jobs, batch transform jobs, and endpoint instances

A *dimension* is a name/value pair that uniquely identifies a metric. You can assign up to 10 dimensions to a metric. For more information on monitoring with CloudWatch, see [Monitor Amazon SageMaker with Amazon CloudWatch \(p. 2523\)](#).

#### Endpoint Invocation Metrics

The AWS/SageMaker namespace includes the following request metrics from calls to [InvokeEndpoint](#).

Metrics are reported at a 1-minute intervals.

Metric	Description
<code>Invocation4XXErrors</code>	The number of <code>InvokeEndpoint</code> requests that the model returned a 4xx HTTP response code for. For each 4xx response, SageMaker sends a 1.  Units: None  Valid statistics: Average, Sum
<code>Invocation5XXErrors</code>	The number of <code>InvokeEndpoint</code> requests that the model returned a 5xx HTTP response code for. For each 5xx response, SageMaker sends a 1.  Units: None  Valid statistics: Average, Sum

Metric	Description
Invocations	<p>The number of <code>InvokeEndpoint</code> requests sent to a model endpoint.</p> <p>To get the total number of requests sent to a model endpoint, use the <code>Sum</code> statistic.</p> <p>Units: None</p> <p>Valid statistics: <code>Sum</code>, <code>Sample Count</code></p>
InvocationsPerInstance	<p>The number of endpoint invocations sent to a model, normalized by <code>InstanceCount</code> in each <code>ProductionVariant</code>. SageMaker sends <math>1/\text{numberOfInstances}</math> as the value for each request, where <code>numberOfInstances</code> is the number of active instances for the <code>ProductionVariant</code> at the endpoint at the time of the request.</p> <p>Units: None</p> <p>Valid statistics: <code>Sum</code></p>
ModelLatency	<p>The time the model or models took to respond. This includes the time it took to send the request, to fetch the response from the model container, and to complete the inference in the container. <code>ModelLatency</code> is the total time taken by all containers in an inference pipeline.</p> <p>Units: Microseconds</p> <p>Valid statistics: <code>Average</code>, <code>Sum</code>, <code>Min</code>, <code>Max</code>, <code>Sample Count</code></p>
OverheadLatency	<p>The time added to the time taken to respond to a client request by SageMaker for overhead. <code>OverheadLatency</code> is measured from the time that SageMaker receives the request until it returns a response to the client, minus the <code>ModelLatency</code>. Overhead latency can vary depending on request and response payload sizes, request frequency, and authentication or authorization of the request, among other factors.</p> <p>Units: Microseconds</p> <p>Valid statistics: <code>Average</code>, <code>Sum</code>, <code>Min</code>, <code>Max</code>, <code>Sample Count</code></p>
ContainerLatency	<p>The time it took for an Inference Pipelines container to respond as viewed from SageMaker. <code>ContainerLatency</code> includes the time it took to send the request, to fetch the response from the model's container, and to complete inference in the container.</p> <p>Units: Microseconds</p> <p>Valid statistics: <code>Average</code>, <code>Sum</code>, <code>Min</code>, <code>Max</code>, <code>Sample Count</code></p>

#### Dimensions for Endpoint Invocation Metrics

Dimension	Description
<code>EndpointName</code> , <code>VariantName</code> , <code>ContainerName</code>	Filters endpoint invocation metrics for a <code>ProductionVariant</code> at the specified endpoint and for the specified variant.

For an inference pipeline endpoint, CloudWatch lists per-container latency metrics in your account as **Endpoint Container Metrics** and **Endpoint Variant Metrics** in the **SageMaker** namespace, as follows. The **ContainerLatency** metric appears only for inferences pipelines.

For each endpoint and each container, latency metrics display names for the container, endpoint, variant, and metric.

#### Training Job, Batch Transform Job, and Endpoint Instance Metrics

The namespaces `/aws/sagemaker/TrainingJobs`, `/aws/sagemaker/TransformJobs`, and `/aws/sagemaker/Endpoints` include the following metrics for training jobs and endpoint instances.

Metrics are reported at a 1-minute intervals.

Metric	Description
CPUUtilization	<p>The percentage of CPU units that are used by the containers running on an instance. The value ranges from 0% to 100%, and is multiplied by the number of CPUs. For example, if there are four CPUs, <b>CPUUtilization</b> can range from 0% to 400%.</p> <p>For training jobs, <b>CPUUtilization</b> is the CPU utilization of the algorithm container running on the instance.</p> <p>For batch transform jobs, <b>CPUUtilization</b> is the CPU utilization of the transform container running on the instance.</p> <p>For multi-container models, <b>CPUUtilization</b> is the sum of CPU utilization by all containers running on the instance.</p> <p>For endpoint variants, <b>CPUUtilization</b> is the sum of CPU utilization by all of the containers running on the instance.</p> <p>Units: Percent</p>
MemoryUtilization	<p>The percentage of memory that is used by the containers running on an instance. This value ranges from 0% to 100%.</p> <p>For training jobs, <b>MemoryUtilization</b> is the memory used by the algorithm container running on the instance.</p> <p>For batch transform jobs, <b>MemoryUtilization</b> is the memory used by the transform container running on the instance.</p>

Metric	Description
	<p>For multi-container models, <code>MemoryUtilization</code> is the sum of memory used by all containers running on the instance.</p> <p>For endpoint variants, <code>MemoryUtilization</code> is the sum of memory used by all of the containers running on the instance.</p> <p>Units: Percent</p>
<code>GPUUtilization</code>	<p>The percentage of GPU units that are used by the containers running on an instance. <code>GPUUtilization</code> ranges from 0% to 100% and is multiplied by the number of GPUs. For example, if there are four GPUs, <code>GPUUtilization</code> can range from 0% to 400%.</p> <p>For training jobs, <code>GPUUtilization</code> is the GPU used by the algorithm container running on the instance.</p> <p>For batch transform jobs, <code>GPUUtilization</code> is the GPU used by the transform container running on the instance.</p> <p>For multi-container models, <code>GPUUtilization</code> is the sum of GPU used by all containers running on the instance.</p> <p>For endpoint variants, <code>GPUUtilization</code> is the sum of GPU used by all of the containers running on the instance.</p> <p>Units: Percent</p>
<code>GPUMemoryUtilization</code>	<p>The percentage of GPU memory used by the containers running on an instance. <code>GPUMemoryUtilization</code> ranges from 0% to 100% and is multiplied by the number of GPUs. For example, if there are four GPUs, <code>GPUMemoryUtilization</code> can range from 0% to 400%.</p> <p>For training jobs, <code>GPUMemoryUtilization</code> is the GPU memory used by the algorithm container running on the instance.</p> <p>For batch transform jobs, <code>GPUMemoryUtilization</code> is the GPU memory used by the transform container running on the instance.</p> <p>For multi-container models, <code>GPUMemoryUtilization</code> is sum of GPU used by all containers running on the instance.</p> <p>For endpoint variants, <code>GPUMemoryUtilization</code> is the sum of the GPU memory used by all of the containers running on the instance.</p> <p>Units: Percent</p>
<code>DiskUtilization</code>	<p>The percentage of disk space used by the containers running on an instance. <code>DiskUtilization</code> ranges from 0% to 100%. This metric is not supported for batch transform jobs.</p> <p>For training jobs, <code>DiskUtilization</code> is the disk space used by the algorithm container running on the instance.</p> <p>For endpoint variants, <code>DiskUtilization</code> is the sum of the disk space used by all of the provided containers running on the instance.</p> <p>Units: Percent</p>

### Dimensions for Training Job, Batch Transform Job, and Endpoint Instance Metrics

Dimension	Description
Host	<p>For training jobs, Host has the format [training-job-name]/algo-[instance-number-in-cluster]. Use this dimension to filter instance metrics for the specified training job and instance. This dimension format is present only in the /aws/sagemaker/TrainingJobs namespace.</p> <p>For batch transform jobs, Host has the format [transform-job-name]/[instance-id]. Use this dimension to filter instance metrics for the specified batch transform job and instance. This dimension format is present only in the /aws/sagemaker/TransformJobs namespace.</p> <p>For endpoints, Host has the format [endpoint-name]/[production-variant-name]/[instance-id]. Use this dimension to filter instance metrics for the specified endpoint, variant, and instance. This dimension format is present only in the /aws/sagemaker/Endpoints namespace.</p>

To help you debug your training jobs, endpoints, and notebook instance lifecycle configurations, SageMaker also sends anything an algorithm container, a model container, or a notebook instance lifecycle configuration sends to `stdout` or `stderr` to Amazon CloudWatch Logs. You can use this information for debugging and to analyze progress.

### Use Logs to Monitor an Inference Pipeline

The following table lists the log groups and log streams SageMaker sends to Amazon CloudWatch

A *log stream* is a sequence of log events that share the same source. Each separate source of logs into CloudWatch makes up a separate log stream. A *log group* is a group of log streams that share the same retention, monitoring, and access control settings.

#### Logs

Log Group Name	Log Stream Name
/aws/sagemaker/TrainingJobs	[training-job-name]/algo-[instance-number-in-cluster]-[epoch_timestamp]
/aws/sagemaker/Endpoints/[EndpointName]	[production-variant-name]/[instance-id] [production-variant-name]/[instance-id] [production-variant-name]/[instance-id]/[container-name provided in the SageMaker model] (For Inference Pipelines) For Inference Pipelines logs, if you don't provide container names, CloudWatch uses **container-1, container-2**, and so on, in the order that containers are provided in the model.
/aws/sagemaker/NotebookInstances	[notebook-instance-name]/[LifecycleConfigHook]
/aws/sagemaker/TransformJobs	[transform-job-name]/[instance-id]-[epoch_timestamp] [transform-job-name]/[instance-id]-[epoch_timestamp]/data-log

Log Group Name	Log Stream Name
	[transform-job-name]/[instance-id]-[epoch_timestamp]/[container-name provided in the SageMaker model] (For Inference Pipelines) For Inference Pipelines logs, if you don't provide container names, CloudWatch uses **container-1, container-2**, and so on, in the order that containers are provided in the model.

**Note**

SageMaker creates the /aws/sagemaker/NotebookInstances log group when you create a notebook instance with a lifecycle configuration. For more information, see [Customize a Notebook Instance Using a Lifecycle Configuration Script \(p. 124\)](#).

For more information about SageMaker logging, see [Log Amazon SageMaker Events with Amazon CloudWatch \(p. 2534\)](#).

## Troubleshoot Inference Pipelines

To troubleshoot inference pipeline issues, use CloudWatch logs and error messages. If you are using custom Docker images in a pipeline that includes Amazon SageMaker built-in algorithms, you might also encounter permissions problems. To grant the required permissions, create an Amazon Elastic Container Registry (Amazon ECR) policy.

**Topics**

- [Troubleshoot Amazon ECR Permissions for Inference Pipelines \(p. 1929\)](#)
- [Use CloudWatch Logs to Troubleshoot SageMaker Inference Pipelines \(p. 1929\)](#)
- [Use Error Messages to Troubleshoot Inference Pipelines \(p. 1930\)](#)

## Troubleshoot Amazon ECR Permissions for Inference Pipelines

When you use custom Docker images in a pipeline that includes [SageMaker built-in algorithms](#), you need an [Amazon ECR policy](#). The policy allows your Amazon ECR repository to grant permission for SageMaker to pull the image. The policy must add the following permissions:

```
{
    "Version": "2008-10-17",
    "Statement": [
        {
            "Sid": "allowSageMakerToPull",
            "Effect": "Allow",
            "Principal": {
                "Service": "sagemaker.amazonaws.com"
            },
            "Action": [
                "ecr:GetDownloadUrlForLayer",
                "ecr:BatchGetImage",
                "ecr:BatchCheckLayerAvailability"
            ]
        }
    ]
}
```

## Use CloudWatch Logs to Troubleshoot SageMaker Inference Pipelines

SageMaker publishes the container logs for endpoints that deploy an inference pipeline to Amazon CloudWatch at the following path for each container.

```
/aws/sagemaker/Endpoints/{EndpointName}/{Variant}/{InstanceId}/{ContainerHostname}
```

For example, logs for this endpoint are published to the following log groups and streams:

```
EndpointName: MyInferencePipelinesEndpoint
Variant: MyInferencePipelinesVariant
InstanceId: i-0179208609ff7e488
ContainerHostname: MyContainerName1 and MyContainerName2
```

```
logGroup: /aws/sagemaker/Endpoints/MyInferencePipelinesEndpoint
logStream: MyInferencePipelinesVariant/i-0179208609ff7e488/MyContainerName1
logStream: MyInferencePipelinesVariant/i-0179208609ff7e488/MyContainerName2
```

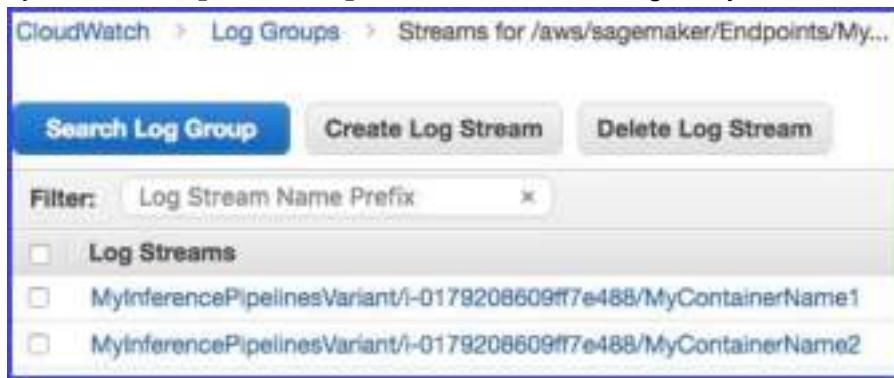

A *log stream* is a sequence of log events that share the same source. Each separate source of logs into CloudWatch makes up a separate log stream. A *log group* is a group of log streams that share the same retention, monitoring, and access control settings.

### To see the log groups and streams

1. Open the CloudWatch console at <https://console.amazonaws.cn/cloudwatch/>.
2. In the navigation page, choose **Logs**.
3. In **Log Groups**, filter on **MyInferencePipelinesEndpoint**:

4. To see the log streams, on the CloudWatch **Log Groups** page, choose **MyInferencePipelinesEndpoint**, and then **Search Log Group**.

For a list of the logs that SageMaker publishes, see [Inference Pipeline Logs and Metrics \(p. 1924\)](#).

### Use Error Messages to Troubleshoot Inference Pipelines

The inference pipeline error messages indicate which containers failed.

If an error occurs while SageMaker is invoking an endpoint, the service returns a `ModelError` (error code 424), which indicates which container failed. If the request payload (the response from the previous container) exceeds the limit of 5 MB, SageMaker provides a detailed error message, such as:

Received response from MyContainerName1 with status code 200. However, the request payload from MyContainerName1 to MyContainerName2 is 6000000 bytes, which has exceeded the maximum limit of 5 MB.

If a container fails the ping health check while SageMaker is creating an endpoint, it returns a `ClientError` and indicates all of the containers that failed the ping check in the last health check.

# Automatically Scale Amazon SageMaker Models

Amazon SageMaker supports automatic scaling (autoscaling) for your hosted models. *Autoscaling* dynamically adjusts the number of instances provisioned for a model in response to changes in your workload. When the workload increases, autoscaling brings more instances online. When the workload decreases, autoscaling removes unnecessary instances so that you don't pay for provisioned instances that you aren't using.

## Topics

- [Prerequisites \(p. 1931\)](#)
- [Configure model autoscaling with the console \(p. 1934\)](#)
- [Register a model \(p. 1935\)](#)
- [Define a scaling policy \(p. 1936\)](#)
- [Apply a scaling policy \(p. 1938\)](#)
- [Edit a scaling policy \(p. 1939\)](#)
- [Delete a scaling policy \(p. 1940\)](#)
- [Query Endpoint Autoscaling History \(p. 1942\)](#)
- [Update or delete endpoints that use automatic scaling \(p. 1943\)](#)
- [Load testing your autoscaling configuration \(p. 1945\)](#)
- [Use Amazon CloudFormation to update autoscaling policies \(p. 1946\)](#)

## Prerequisites

Before you can use autoscaling, must have already created a Amazon SageMaker model deployment. Deployed models are referred to as a [production variant](#). This includes information about the model and the resources used to host it.

For more information about deploying a model endpoint, see [Deploy the Model to SageMaker Hosting Services \(p. 63\)](#).

To enable autoscaling for a model, you can use the console, the Amazon CLI, or the Application Auto Scaling API. It is recommended to try to [Configure model autoscaling with the console \(p. 1934\)](#) to get familiar with the requirements and to test your first autoscaling configuration. When using the Amazon CLI or Application Auto Scaling the flow is to register the model, define the scaling policy, then apply it. The following overview provides further details on the prerequisites and components used with autoscaling.

## Autoscaling policy overview

To use automatic scaling, you define and apply a scaling policy that uses Amazon CloudWatch metrics and target values that you assign. Automatic scaling uses the policy to increase or decrease the number of instances in response to actual workloads.

You can use the Amazon Web Services Management Console to apply a scaling policy based on a predefined metric. A *predefined metric* is defined in an enumeration so that you can specify it by name in code or use it in the Amazon Web Services Management Console. Alternatively, you can use either the Amazon Command Line Interface (Amazon CLI) or the Application Auto Scaling API to apply a scaling policy based on a predefined or custom metric.

There are two types of supported scaling policies: target-tracking scaling and step scaling. It is recommended to use target-tracking scaling policies for your autoscaling configuration. You configure the *target-tracking scaling policy* by specifying a predefined or custom metric and a target value for the metric. For more information about using Application Auto Scaling target-tracking scaling policies, see [Target Tracking Scaling Policies](#).

You can use step scaling when you require an advanced configuration, such as specifying how many instances to deploy under what conditions. Otherwise, using target-tracking scaling is preferred as it will be fully automated. For more information about using Application Auto Scaling step scaling policies, see [Step Scaling Policies](#).

A scaling policy has the following components:

- A target metric—The Amazon CloudWatch metric that SageMaker automatic scaling uses to determine when and how much to scale.
- Minimum and maximum capacity—The minimum and maximum number of instances to use for scaling.
- A cool down period—The amount of time, in seconds, after a scale-in or scale-out activity completes before another scale-out activity can start.
- Required permissions—Permissions that are required to perform automatic scaling actions.
- A service-linked role—An Amazon Identity and Access Management (IAM) role that is linked to a specific Amazon service. A service-linked role includes all of the permissions that the service requires to call other Amazon services on your behalf. SageMaker automatic scaling automatically generates this role, `AWSServiceRoleForApplicationAutoScaling_SageMakerEndpoint`, for you.

## Target metric for autoscaling

Amazon CloudWatch alarms trigger the scaling policy, which calculate how to adjust scaling based on the metric and target value that you set. The scaling policy adds or removes endpoint instances as required to keep the metric at, or close to, the specified target value. In addition, a scaling policy also adjusts to fluctuations in the metric when a workload changes. The scaling policy minimizes rapid fluctuations in the number of available instances for your model.

For example, a scaling policy that uses the predefined `InvocationsPerInstance` metric with a target value of 70 can keep `InvocationsPerInstance` at, or close to 70.

## Minimum and maximum capacity

You may specify the maximum number of endpoint instances for the model. The maximum value must be equal to or greater than the value specified for the minimum number of endpoint instances. SageMaker automatic scaling does not enforce a limit for this value.

You must also specify the minimum number of instances for the model. This value must be at least 1, and equal to or less than the value specified for the maximum number of endpoint instances.

To determine the minimum and maximum number of instances that you need for typical traffic, test your autoscaling configuration with the expected rate of traffic to your model.

### Important

Scaling-in occurs when there is no traffic: if a variant's traffic becomes zero, SageMaker automatically scales in to the minimum number of instances specified. In this case, SageMaker emits metrics with a value of zero. Minimum instance count is required to be 1 or higher.

## Cooldown period

Tune the responsiveness of your scaling policy by adding a cooldown period. A *cooldown period* controls when your model is scaled-in (by reducing instances) or scaled-out (by increasing instances). It does this

by blocking subsequent scale-in or scale-out requests until the period expires. This slows the deletion of instances for scale-in requests, and the creation of instances for scale-out requests. A cooldown period helps to ensure that the scaling policy doesn't launch or terminate additional instances before the previous scaling activity takes effect. After automatic scaling dynamically scales using a scaling policy, it waits for the cooldown period to complete before resuming scaling activities.

You configure the cooldown period in your automatic scaling policy. You can specify the following cooldown periods:

- A scale-in activity reduces the number of instances. A scale-in cooldown period specifies the amount of time, in seconds, after a scale-in activity completes before another scale-in activity can start.
- A scale-out activity increases the number of instances. A scale-out cooldown period specifies the amount of time, in seconds, after a scale-out activity completes before another scale-out activity can start.

If you don't specify a scale-in or a scale-out cooldown period automatic scaling use the default, which is 300 seconds for each.

If instances are being added or removed too quickly when you test your automatic scaling configuration, consider increasing this value. You can see this behavior if the traffic to your model has a lot of spikes, or if you have multiple automatic scaling policies defined for a variant.

If instances are not being added quickly enough to address increased traffic, consider decreasing this value.

## Permissions

The `SagemakerFullAccessPolicy` IAM policy has all of the IAM permissions required to perform autoscaling. For more information about SageMaker IAM permissions, see [SageMaker Roles \(p. 2447\)](#).

If you are using a custom permission policy, you must include the following permissions:

```
{
    "Effect": "Allow",
    "Action": [
        "sagemaker:DescribeEndpoint",
        "sagemaker:DescribeEndpointConfig",
        "sagemaker:UpdateEndpointWeightsAndCapacities"
    ],
    "Resource": "*"
}
{
    "Action": [
        "application-autoscaling:)"
    ],
    "Effect": "Allow",
    "Resource": "*"
}

{
    "Action": "iam:CreateServiceLinkedRole",
    "Effect": "Allow",
    "Resource": "arn:aws:iam::*:role/aws-service-role/sagemaker.application-autoscaling.amazonaws.com/
AWSServiceRoleForApplicationAutoScaling_SageMakerEndpoint",
    "Condition": {
        "StringLike": { "iam:AWSServiceName": "sagemaker.application-
autoscaling.amazonaws.com" }
    }
}
```

```
        }
      {
        "Effect": "Allow",
        "Action": [
          "cloudwatch:PutMetricAlarm",
          "cloudwatch:DescribeAlarms",
          "cloudwatch:DeleteAlarms"
        ],
        "Resource": "*"
      }
```

## Service-linked role

Autoscaling uses the `AWSServiceRoleForApplicationAutoScaling_SageMakerEndpoint` service-linked role; it created for you automatically. A service-linked role is a unique type of IAM role that is linked directly to an Amazon service. Service-linked roles are predefined by the service and include all of the permissions that the service requires to call other Amazon services on your behalf. For more information, see [Service-Linked Roles](#).

## Configure model autoscaling with the console

### To configure autoscaling for a model using the console

1. Open the Amazon SageMaker console at <https://console.amazonaws.cn/sagemaker/>.
2. In the navigation pane, choose **Endpoints**.
3. Choose the endpoint that you want to configure.
4. For **Endpoint runtime settings**, choose the model variant that you want to configure.
5. For **Endpoint runtime settings**, choose **Configure autoscaling**.

The **Configure variant automatic scaling** page appears.

6. For **Minimum capacity**, type the minimum number of instances that you want the scaling policy to maintain. At least 1 instance is required.
7. For **Maximum capacity**, type the maximum number of instances that you want the scaling policy to maintain.
8. For the **target value**, type the average number of invocations per instance per minute for the model. To determine this value, follow the guidelines in [Load testing \(p. 1945\)](#).

Application Auto Scaling adds or removes instances to keep the metric close to the value that you specify.

9. For **Scale-in cool down (seconds)** and **Scale-out cool down (seconds)**, type the number seconds for each cool down period. Assuming that the order in the list is based on either most important to less important of first applied to last applied.
10. Select **Disable scale in** to prevent the scaling policy from deleting variant instances if you want to ensure that your variant scales out to address increased traffic, but are not concerned with removing instances to reduce costs when traffic decreases, disable scale-in activities.

Scale-out activities are always enabled so that the scaling policy can create endpoint instances as needed.

11. Choose **Save**.

This procedure registers a model as a scalable target with Application Auto Scaling. When you register a model, Application Auto Scaling performs validation checks to ensure the following:

- The model exists

- The permissions are sufficient
- You aren't registering a variant with an instance that is a burstable performance instance such as T2

**Note**

SageMaker doesn't support autoscaling for burstable instances such as T2, because they already allow for increased capacity under increased workloads. For information about burstable performance instances, see [Amazon EC2 Instance Types](#).

## Register a model

You can add autoscaling for a model with the Amazon CLI or the Application Auto Scaling API. You first must register the model, then you must define an autoscaling policy.

### Register a model with the Amazon CLI

With the Amazon CLI, you can configure autoscaling based on either a predefined or a custom metric.

To register your endpoint, use the `register-scalable-target` Amazon CLI command with the following parameters:

- `--service-namespace`—Set this value to `sagemaker`.
- `--resource-id`—The resource identifier for the model (specifically, the production variant). For this parameter, the resource type is `endpoint` and the unique identifier is the name of the production variant. For example, `endpoint/MyEndPoint/variant/MyVariant`.
- `--scalable-dimension`—Set this value to `sagemaker:variant:DesiredInstanceCount`.
- `--min-capacity`—The minimum number of instances that for this model. Set `min-capacity` to at least 1. It must be equal to or less than the value specified for `max-capacity`.
- `--max-capacity`—The maximum number of instances that Application Auto Scaling should manage. Set `max-capacity` to a minimum of 1, It must be equal to or greater than the value specified for `min-capacity`.

#### Example

The following example shows how to register a model named `MyVariant` that is dynamically scaled to have one to eight instances:

```
aws application-autoscaling register-scalable-target \
--service-namespace sagemaker \
--resource-id endpoint/MyEndPoint/variant/MyVariant \
--scalable-dimension sagemaker:variant:DesiredInstanceCount \
--min-capacity 1 \
--max-capacity 8
```

### Register a model with the Application Auto Scaling API

To define the scaling limits for the model, register your model with Application Auto Scaling. Application Auto Scaling dynamically scales the number of production variant instances.

To register your model with Application Auto Scaling, use the `RegisterScalableTarget` Application Auto Scaling API action with the following parameters:

- `ServiceNamespace`—Set this value to `sagemaker`.
- `ResourceId`—The resource identifier for the production variant. For this parameter, the resource type is `endpoint` and the unique identifier is the name of the variant, for example `endpoint/MyEndPoint/variant/MyVariant`.

- **ScalableDimension**—Set this value to `sagemaker:variant:DesiredInstanceCount`.
- **MinCapacity**—The minimum number of instances to be managed by Application Auto Scaling. This value must be set to at least 1 and must be equal to or less than the value specified for **MaxCapacity**.
- **MaxCapacity**—The maximum number of instances to be managed by Application Auto Scaling. This value must be set to at least 1 and must be equal to or greater than the value specified for **MinCapacity**.

### Example

The following example shows how to register a SageMaker production variant that is dynamically scaled to use one to eight instances:

```
POST / HTTP/1.1
Host: autoscaling.us-east-2.amazonaws.com
Accept-Encoding: identity
X-Amz-Target: AnyScaleFrontendService.RegisterScalableTarget
X-Amz-Date: 20160506T182145Z
User-Agent: aws-cli/1.10.23 Python/2.7.11 Darwin/15.4.0 botocore/1.4.8
Content-Type: application/x-amz-json-1.1
Authorization: AUTHPARAMS

{
    "ServiceNamespace": "sagemaker",
    "ResourceId": "endpoint/MyEndPoint/variant/MyVariant",
    "ScalableDimension": "sagemaker:variant:DesiredInstanceCount",
    "MinCapacity": 1,
    "MaxCapacity": 8
}
```

## Define a scaling policy

To specify the metrics and target values for a scaling policy, you configure a target-tracking scaling policy. You can use either a predefined metric or a custom metric.

Scaling policy configuration is represented by a JSON block. You save your scaling policy configuration as a JSON block in a text file. You use that text file when invoking the Amazon CLI or the Application Auto Scaling API. For more information about policy configuration syntax, see [TargetTrackingScalingPolicyConfiguration](#) in the *Application Auto Scaling API Reference*.

The following options are available for defining a target-tracking scaling policy configuration.

### Use a predefined metric

To quickly define a target-tracking scaling policy for a variant, use the `SageMakerVariantInvocationsPerInstance` predefined metric.

`SageMakerVariantInvocationsPerInstance` is the average number of times per minute that each instance for a variant is invoked. We strongly recommend using this metric.

To use a predefined metric in a scaling policy, create a target tracking configuration for your policy. In the target tracking configuration, include a `PredefinedMetricSpecification` for the predefined metric and a `TargetValue` for the target value of that metric.

### Example

The following example is a typical policy configuration for target-tracking scaling for a variant. In this configuration, we use the `SageMakerVariantInvocationsPerInstance` predefined metric to adjust the number of variant instances so that each instance has a `InvocationsPerInstance` metric of 70.

```
{  
    "TargetValue": 70.0,  
    "PredefinedMetricSpecification":  
    {  
        "PredefinedMetricType": "SageMakerVariantInvocationsPerInstance"  
    }  
}
```

## Use a custom metric

If you need to define a target-tracking scaling policy that meets your custom requirements, define a custom metric. You can define a custom metric based on any production variant metric that changes in proportion to scaling.

Not all SageMaker metrics work for target tracking. The metric must be a valid utilization metric, and it must describe how busy an instance is. The value of the metric must increase or decrease in inverse proportion to the number of variant instances. That is, the value of the metric should decrease when the number of instances increases.

**Important**

Before deploying automatic scaling in production, you must test automatic scaling with your custom metric.

### Example

The following example is a target-tracking configuration for a scaling policy. In this configuration, for a variant named `my-variant`, a custom metric adjusts the variant based on an average CPU utilization of 50 percent across all instances.

```
{  
    "TargetValue": 50,  
    "CustomizedMetricSpecification":  
    {  
        "MetricName": "CPUUtilization",  
        "Namespace": "/aws/sagemaker/Endpoints",  
        "Dimensions": [  
            {"Name": "EndpointName", "Value": "my-endpoint"},  
            {"Name": "VariantName", "Value": "my-variant"}  
        ],  
        "Statistic": "Average",  
        "Unit": "Percent"  
    }  
}
```

## Add a cooldown period

To add a cooldown period for scaling-out your model, specify a value, in seconds, for `ScaleOutCooldown`. Similarly, to add a cooldown period for scaling-in your model, add a value, in seconds, for `ScaleInCooldown`. For more information about `ScaleInCooldown` and `ScaleOutCooldown`, see [TargetTrackingScalingPolicyConfiguration](#) in the *Application Auto Scaling API Reference*.

### Example

The following is an example target-tracking configuration for a scaling policy. In this configuration, the `SageMakerVariantInvocationsPerInstance` predefined metric is used to adjust scaling based on an average of 70 across all instances of that variant. The configuration provides a scale-in cooldown period of 10 minutes and a scale-out cooldown period of 5 minutes.

```
{  
    "TargetValue": 70.0,  
    "PredefinedMetricSpecification":  
    {  
        "PredefinedMetricType": "SageMakerVariantInvocationsPerInstance"  
    },  
    "ScaleInCooldown": 600,  
    "ScaleOutCooldown": 300  
}
```

## Apply a scaling policy

After registering your model and defining a scaling policy, apply the scaling policy to the registered model. To apply a scaling policy, you can use the Amazon CLI or the Application Auto Scaling API.

### Apply a scaling policy (Amazon CLI)

To apply a scaling policy to your model, use the [put-scaling-policy](#) Amazon CLI command with the following parameters:

- **--policy-name**—The name of the scaling policy.
- **--policy-type**—Set this value to `TargetTrackingScaling`.
- **--resource-id**—The resource identifier for the variant. For this parameter, the resource type is `endpoint` and the unique identifier is the name of the variant. For example `endpoint/MyEndpoint/variant/MyVariant`.
- **--service-namespace**—Set this value to `sagemaker`.
- **--scalable-dimension**—Set this value to `sagemaker:variant:DesiredInstanceCount`.
- **--target-tracking-scaling-policy-configuration**—The target-tracking scaling policy configuration to use for the model.

#### Example

The following example uses with Application Auto Scaling to apply a target-tracking scaling policy named `myscalablepolicy` to a model (variant) named `myscalablevariant`. The policy configuration is saved in a file named `config.json`.

```
aws application-autoscaling put-scaling-policy \  
    --policy-name myscalablepolicy \  
    --policy-type TargetTrackingScaling \  
    --resource-id endpoint/MyEndpoint/variant/MyVariant \  
    --service-namespace sagemaker \  
    --scalable-dimension sagemaker:variant:DesiredInstanceCount \  
    --target-tracking-scaling-policy-configuration file://config.json
```

### Apply a scaling policy (Application Auto Scaling API)

To apply a scaling policy to a variant with the Application Auto Scaling API, use the [PutScalingPolicy](#) Application Auto Scaling API action with the following parameters:

- **PolicyName**—The name of the scaling policy.
- **ServiceNamespace**—Set this value to `sagemaker`.
- **ResourceID**—The resource identifier for the variant. For this parameter, the resource type is `endpoint` and the unique identifier is the name of the variant. For example, `endpoint/MyEndpoint/variant/MyVariant`.
- **ScalableDimension**—Set this value to `sagemaker:variant:DesiredInstanceCount`.

- **PolicyType**—Set this value to `TargetTrackingScaling`.
- **TargetTrackingScalingPolicyConfiguration**—The target-tracking scaling policy configuration to use for the variant.

### Example

The following example uses Application Auto Scaling to apply a target-tracking scaling policy named `mscalablepolicy` to a variant named `mscalablevariant`. It uses a policy configuration based on the `SageMakerVariantInvocationsPerInstance` predefined metric.

```
POST / HTTP/1.1
Host: autoscaling.us-east-2.amazonaws.com
Accept-Encoding: identity
X-Amz-Target: AnyScaleFrontendService.
X-Amz-Date: 20160506T182145Z
User-Agent: aws-cli/1.10.23 Python/2.7.11 Darwin/15.4.0 botocore/1.4.8
Content-Type: application/x-amz-json-1.1
Authorization: AUTHPARAMS

{
    "PolicyName": "mscalablepolicy",
    "ServiceNamespace": "sagemaker",
    "ResourceId": "endpoint/MyEndpoint/variant/MyVariant",
    "ScalableDimension": "sagemaker:variant:DesiredInstanceCount",
    "PolicyType": "TargetTrackingScaling",
    "TargetTrackingScalingPolicyConfiguration": {
        "TargetValue": 70.0,
        "PredefinedMetricSpecification":
        {
            "PredefinedMetricType": "SageMakerVariantInvocationsPerInstance"
        }
    }
}
```

## Edit a scaling policy

You can edit an autoscaling policy with the Amazon Web Services Management Console, the Amazon CLI, or the Application Auto Scaling API.

### Scale-in

Scaling-in occurs when there is no traffic: if a variant's traffic becomes zero, SageMaker automatically scales in to the minimum number of instances specified. In this case, SageMaker emits metrics with a value of zero. Minimum instance count is required to be 1 or higher.

### Disable scale-in activity

You can prevent the target-tracking scaling policy configuration from scaling in your variant by disabling scale-in activity. Disabling scale-in activity prevents the scaling policy from deleting instances, while still allowing it to create them as needed.

To enable or disable scale-in activity for your model, specify a Boolean value for `DisableScaleIn`. For more information about `DisableScaleIn`, see [TargetTrackingScalingPolicyConfiguration](#) in the *Application Auto Scaling API Reference*.

### Example

The following is an example of a target-tracking configuration for a scaling policy where it will scale-out, but not scale-in. In this configuration, the `SageMakerVariantInvocationsPerInstance` predefined

metric will scale-out based on an average of 70 invocations (inference requests) across all instances the model is on. The configuration also disables scale-in activity for the scaling policy.

```
{  
    "TargetValue": 70.0,  
    "PredefinedMetricSpecification":  
    {  
        "PredefinedMetricType": "SageMakerVariantInvocationsPerInstance"  
    },  
    "DisableScaleIn": true  
}
```

## Scale-out

To manually scale-out, adjust the minimum capacity. You can use the console to update this value. Alternatively, use the Amazon CLI with the `--min-capacity` argument, or use the Application Auto Scaling API's `MinCapacity` parameter.

### Disable scale-out activity

To prevent scale-out, adjust the maximum capacity. You can use the console to update this value. Alternatively, use the Amazon CLI with the `--max-capacity` argument, or use the Application Auto Scaling API's `MaxCapacity` parameter.

## Edit a scaling policy (Console)

To edit a scaling policy with the Amazon Web Services Management Console, use the same procedure that you used to [Configure model autoscaling with the console \(p. 1934\)](#).

## Edit a scaling policy (Amazon CLI or Application Auto Scaling API)

You can use the Amazon CLI or the Application Auto Scaling API to edit a scaling policy in the same way that you apply a scaling policy:

- With the Amazon CLI, specify the name of the policy that you want to edit in the `--policy-name` parameter. Specify new values for the parameters that you want to change.
- With the Application Auto Scaling API, specify the name of the policy that you want to edit in the `PolicyName` parameter. Specify new values for the parameters that you want to change.

For more information, see [Apply a scaling policy \(p. 1938\)](#).

## Delete a scaling policy

You can delete a scaling policy with the Amazon Web Services Management Console, the Amazon CLI, or the Application Auto Scaling API. You must delete a scaling policy if you wish to update a model's endpoint.

## Delete a scaling policy (Console)

### To delete an automatic scaling policy (console)

- Open the Amazon SageMaker console at <https://console.amazonaws.cn/sagemaker/>.

2. In the navigation pane, choose **Endpoints**.
3. Choose the endpoint for which you want to delete automatic scaling.
4. For **Endpoint runtime settings**, choose the variant that you want to configure.
5. Choose **Configure auto scaling**.
6. Choose **Deregister auto scaling**.

## Delete a scaling policy (Amazon CLI or Application Auto Scaling API)

You can use the Amazon CLI or the Application Auto Scaling API to delete a scaling policy from a variant.

### Delete a scaling policy (Amazon CLI)

To delete a scaling policy from a variant, use the [delete-scaling-policy](#) Amazon CLI command with the following parameters:

- **--policy-name**—The name of the scaling policy.
- **--resource-id**—The resource identifier for the variant. For this parameter, the resource type is `endpoint` and the unique identifier is the name of the variant. For example, `endpoint/MyEndpoint/variant/MyVariant`.
- **--service-namespace**—Set this value to `sagemaker`.
- **--scalable-dimension**—Set this value to `sagemaker:variant:DesiredInstanceCount`.

### Example

The following example deletes a target-tracking scaling policy named `mscalablepolicy` from a variant named `mscalablevariant`.

```
aws application-autoscaling delete-scaling-policy \
  --policy-name mscalablepolicy \
  --resource-id endpoint/MyEndpoint/variant/MyVariant \
  --service-namespace sagemaker \
  --scalable-dimension sagemaker:variant:DesiredInstanceCount
```

### Delete a scaling policy (Application Auto Scaling API)

To delete a scaling policy from your variant, use the [DeleteScalingPolicy](#) Application Auto Scaling API action with the following parameters:

- **PolicyName**—The name of the scaling policy.
- **ServiceNamespace**—Set this value to `sagemaker`.
- **ResourceID**—The resource identifier for the variant. For this parameter, the resource type is `endpoint` and the unique identifier is the name of the variant., For example, `endpoint/MyEndpoint/variant/MyVariant`.
- **ScalableDimension**—Set this value to `sagemaker:variant:DesiredInstanceCount`.

### Example

The following example uses the Application Auto Scaling API to delete a target-tracking scaling policy named `mscalablepolicy` from a variant named `mscalablevariant`.

```
POST / HTTP/1.1
Host: autoscaling.us-east-2.amazonaws.com
Accept-Encoding: identity
X-Amz-Target: AnyScaleFrontendService.DeleteScalingPolicy
X-Amz-Date: 20160506T182145Z
User-Agent: aws-cli/1.10.23 Python/2.7.11 Darwin/15.4.0 botocore/1.4.8
Content-Type: application/x-amz-json-1.1
Authorization: AUTHPARAMS

{
    "PolicyName": "myscalablepolicy",
    "ServiceNamespace": "sagemaker",
    "ResourceId": "endpoint/MyEndpoint/variant/MyVariant",
    "ScalableDimension": "sagemaker:variant:DesiredInstanceCount"
}
```

## Query Endpoint Autoscaling History

You can view the status of scaling activities from your endpoint using [DescribeScalingActivities](#). `DescribeScalingActivities` provides descriptive information about the scaling activities in the specified namespace from the previous six weeks.

### How To Query Endpoint Autoscaling Actions

Query your autoscaling endpoints with `DescribeScalingActivities`. To do so, specify `ServiceNameSpace` parameter. `ServiceNameSpace` is the name of the Amazon service that provides the resource.

Valid service name values include the following:

```
ecs | elasticmapreduce | ec2 | appstream | dynamodb | rds | sagemaker | custom-
resource | comprehend | lambda | cassandra
```

In this situation you need to set `ServiceNameSpace` to `sagemaker`.

Use the following Amazon CLI command to view details about all of your `sagemaker` endpoints that have a scaling policy:

```
aws application-autoscaling describe-scaling-activities \
--service-namespace sagemaker
```

You can search for a specific endpoint using `ResourceId`:

```
aws application-autoscaling describe-scaling-activities \
--service-namespace sagemaker \
--resource-id endpoint/<endpoint_name>/variant/<variant_name>
```

When you run this command, it returns the following output:

```
{
    "ActivityId": "activity-id",
    "ServiceNamespace": "sagemaker",
    "ResourceId": "endpoint/<endpoint_name>/variant/<variant_name>",
    "ScalableDimension": "sagemaker:variant:DesiredInstanceCount",
    "Description": "string",
    "Cause": "string",
    "StartTime": timestamp,
```

```
        "EndTime": timestamp,  
        "StatusCode": "string",  
        "StatusMessage": "string"  
    }
```

## How to Identify Blocked AutoScaling Due to Instance Quotas

When you scale out or add more instances, you might reach your account-level instance quota. You can use `DescribeScalingActivities` to check whether you have reached your instance quota. When you exceed your quota, automatic scaling is blocked.

To check if you have reached your instance quota, use the Amazon CLI command as shown in the proceeding example where you specified the `ResourceId`:

```
aws application-autoscaling describe-scaling-activities \  
  --service-namespace sagemaker \  
  --resource-id endpoint/<endpoint_name>/variant/<variant_name>
```

Within the return syntax, check the `StatusCode` and `StatusMessage` keys and their associated values. `StatusCode` returns `Failed`. Within `StatusMessage` there is a message indicating that the account-level service quota was reached. The following is an example of what that message might look like:

```
{  
    "ActivityId": "activity-id",  
    "ServiceNamespace": "sagemaker",  
    "ResourceId": "endpoint/<endpoint_name>/variant/<variant_name>",  
    "ScalableDimension": "sagemaker:variant:DesiredInstanceCount",  
    "Description": "string",  
    "Cause": "minimum capacity was set to 110",  
    "StartTime": timestamp,  
    "EndTime": timestamp,  
    "StatusCode": "Failed",  
    "StatusMessage": "Failed to set desired instance count to 110. Reason: The account-level service limit 'ml.xx.xxxxxxx for endpoint usage' is 1000 Instances, with current utilization of 997 Instances and a request delta of 20 Instances. Please contact Amazon support to request an increase for this limit. (Service: AmazonSageMaker; Status Code: 400; Error Code: ResourceLimitExceeded; Request ID: request-id)."  
}
```

## Update or delete endpoints that use automatic scaling

### Topics

- [Update endpoints that use automatic scaling \(p. 1943\)](#)
- [Delete endpoints configured for automatic scaling \(p. 1944\)](#)

## Update endpoints that use automatic scaling

When you update an endpoint, Application Auto Scaling checks to see whether any of the models on that endpoint are targets for automatic scaling. If the update would change the instance type for any model that is a target for automatic scaling, the update fails.

In the Amazon Web Services Management Console, you see a warning that you must deregister the model from automatic scaling before you can update it. If you are trying to update the endpoint by

calling the [UpdateEndpoint](#) API, the call fails. Before you update the endpoint, delete any scaling policies configured for it by calling the [DeleteScalingPolicy](#) Application Auto Scaling API action, then call [DeregisterScalableTarget](#) to deregister the variant as a scalable target. After you update the endpoint, you can register the variant as a scalable target and attach an automatic scaling policy to the updated variant.

There is one exception. If you change the model for a variant that is configured for automatic scaling, Amazon SageMaker automatic scaling allows the update. This is because changing the model doesn't typically affect performance enough to change automatic scaling behavior. If you do update a model for a variant configured for automatic scaling, ensure that the change to the model doesn't significantly affect performance and automatic scaling behavior.

When you update SageMaker endpoints that have automatic scaling applied, complete the following steps:

### To update an endpoint that has automatic scaling applied

1. Deregister the endpoint as a scalable target by calling [DeregisterScalableTarget](#).
2. Because automatic scaling is blocked while the update operation is in progress (or if you turned off automatic scaling in the previous step), you might want to take the additional precaution of increasing the number of instances for your endpoint during the update. To do this, update the instance counts for the production variants hosted at the endpoint by calling [UpdateEndpointWeightsAndCapacities](#).
3. Call [DescribeEndpoint](#) repeatedly until the value of the `EndpointStatus` field of the response is `InService`.
4. Call [DescribeEndpointConfig](#) to get the values of the current endpoint config.
5. Create a new endpoint config by calling [CreateEndpointConfig](#). For the production variants where you want to keep the existing instance count or weight, use the same variant name from the response from the call to [DescribeEndpointConfig](#) in the previous step. For all other values, use the values that you got as the response when you called [DescribeEndpointConfig](#) in the previous step.
6. Update the endpoint by calling [UpdateEndpoint](#). Specify the endpoint config you created in the previous step as the `EndpointConfig` field. If you want to retain the variant properties like instance count or weight, set the value of the `RetainAllVariantProperties` parameter to `True`. This specifies that production variants with the same name will be updated with the most recent `DesiredInstanceCount` from the response from the call to [DescribeEndpoint](#), regardless of the values of the `InitialInstanceCount` field in the new `EndpointConfig`.
7. (Optional) Re-enable automatic scaling by calling [RegisterScalableTarget](#).

#### Note

Steps 1 and 7 are required only if you are updating an endpoint with the following changes:

- Changing the instance type for a production variant that has automatic scaling configured
- Removing a production variant that has automatic scaling configured.

## Delete endpoints configured for automatic scaling

If you delete an endpoint, Application Auto Scaling checks to see whether any of the models on that endpoint are targets for automatic scaling. If any are and you have permission to deregister the model, Application Auto Scaling deregisters those models as scalable targets without notifying you. If you use a custom permission policy that doesn't provide permission for the [DeleteScalingPolicy](#) and [DeregisterScalableTarget](#) actions, you must delete automatic scaling policies and deregister scalable targets and before deleting the endpoint.

**Note**

You, as an IAM user, might not have sufficient permission to delete an endpoint if another IAM user configured automatic scaling for a variant on that endpoint.

## Load testing your autoscaling configuration

Perform load tests to choose an automatic scaling configuration that works the way you want.

For an example of load testing to optimize automatic scaling for an Amazon SageMaker endpoint, see [Load test and optimize an Amazon SageMaker endpoint using automatic scaling](#).

The following guidelines for load testing assume you are using an automatic scaling policy that uses the predefined target metric `SageMakerVariantInvocationsPerInstance`.

**Topics**

- [Determine the performance characteristics \(p. 1945\)](#)
- [Calculate the target load \(p. 1945\)](#)

## Determine the performance characteristics

Perform load testing to find the peak `InvocationsPerInstance` that your model's production variant can handle, and the latency of requests, as concurrency increases.

This value depends on the instance type chosen, payloads that clients of your model typically send, and the performance of any external dependencies your model has.

### To find the peak requests-per-second (RPS) your model's production variant can handle and latency of requests

1. Set up an endpoint with your model using a single instance. For information about how to set up an endpoint, see [Deploy the Model to SageMaker Hosting Services \(p. 63\)](#).
2. Use a load testing tool to generate an increasing number of parallel requests, and monitor the RPS and model latency in the output of the load testing tool.

**Note**

You can also monitor requests-per-minute instead of RPS. In that case don't multiply by 60 in the equation to calculate `SageMakerVariantInvocationsPerInstance` shown below.

When the model latency increases or the proportion of successful transactions decreases, this is the peak RPS that your model can handle.

## Calculate the target load

After you find the performance characteristics of the variant, you can determine the maximum RPS we should allow to be sent to an instance. The threshold used for scaling must be less than this maximum value. Use the following equation in combination with load testing to determine the correct value for the `SageMakerVariantInvocationsPerInstance` target metric in your automatic scaling configuration.

```
SageMakerVariantInvocationsPerInstance = (MAX_RPS * SAFETY_FACTOR) * 60
```

Where `MAX_RPS` is the maximum RPS that you determined previously, and `SAFETY_FACTOR` is the safety factor that you chose to ensure that your clients don't exceed the maximum RPS. Multiply by 60 to convert from RPS to invocations-per-minute to match the per-minute CloudWatch metric that SageMaker uses to implement automatic scaling (you don't need to do this if you measured requests-per-minute instead of requests-per-second).

**Note**

SageMaker recommends that you start testing with a `SAFETY_FACTOR` of 0.5. Test your automatic scaling configuration to ensure it operates in the way you expect with your model for both increasing and decreasing customer traffic on your endpoint.

## Use Amazon CloudFormation to update autoscaling policies

The following is an example for how to enable autoscaling on an endpoint using Amazon CloudFormation.

```
Endpoint:  
  Type: "AWS::SageMaker::Endpoint"  
  Properties:  
    EndpointName: yourEndpointName  
    EndpointConfigName: yourEndpointConfigName  
  
  ScalingTarget:  
    Type: "AWS::ApplicationAutoScaling::ScalableTarget"  
    Properties:  
      MaxCapacity: 10  
      MinCapacity: 2  
      ResourceId: endpoint/MyEndPoint/variant/MyVariant  
      RoleARN: arn  
      ScalableDimension: sagemaker:variant:DesiredInstanceCount  
      ServiceNamespace: sagemaker  
  
  ScalingPolicy:  
    Type: "AWS::ApplicationAutoScaling::ScalingPolicy"  
    Properties:  
      PolicyName: myscalablepolicy  
      PolicyType: TargetTrackingScaling  
      ScalingTargetId:  
        Ref: ScalingTarget  
      TargetTrackingScalingPolicyConfiguration:  
        TargetValue: 75.0  
        ScaleInCooldown: 600  
        ScaleOutCooldown: 30  
      PredefinedMetricSpecification:  
        PredefinedMetricType: SageMakerVariantInvocationsPerInstance
```

For more details, refer to CloudFront's [AutoScalingPlans API reference](#).

## Host Instance Storage Volumes

When you create an endpoint, Amazon SageMaker attaches an Amazon Elastic Block Store (Amazon EBS) storage volume to Amazon EC2 instances that hosts the endpoint. The size of the storage volume is scalable, and storage options are divided into two categories: SSD-backed storage and HDD-backed storage.

For more information about Amazon EBS storages and features, see the following pages.

- [Amazon EBS Features](#)
- [Amazon EBS User Guide](#)

For a full list of the host instance storage volumes, see [Host Instance Storage Volumes Table](#)

# Test models in production

In production ML workflows, data scientists and engineers frequently try to improve their models in various ways, such as by performing [Perform Automatic Model Tuning with SageMaker \(p. 1745\)](#), training on additional or more-recent data, and improving feature selection. Performing A/B testing between a new model and an old model with production traffic can be an effective final step in the validation process for a new model. In A/B testing, you test different variants of your models and compare how each variant performs. If the newer version of the model delivers better performance than the previously-existing version, replace the old version of the model with the new version in production.

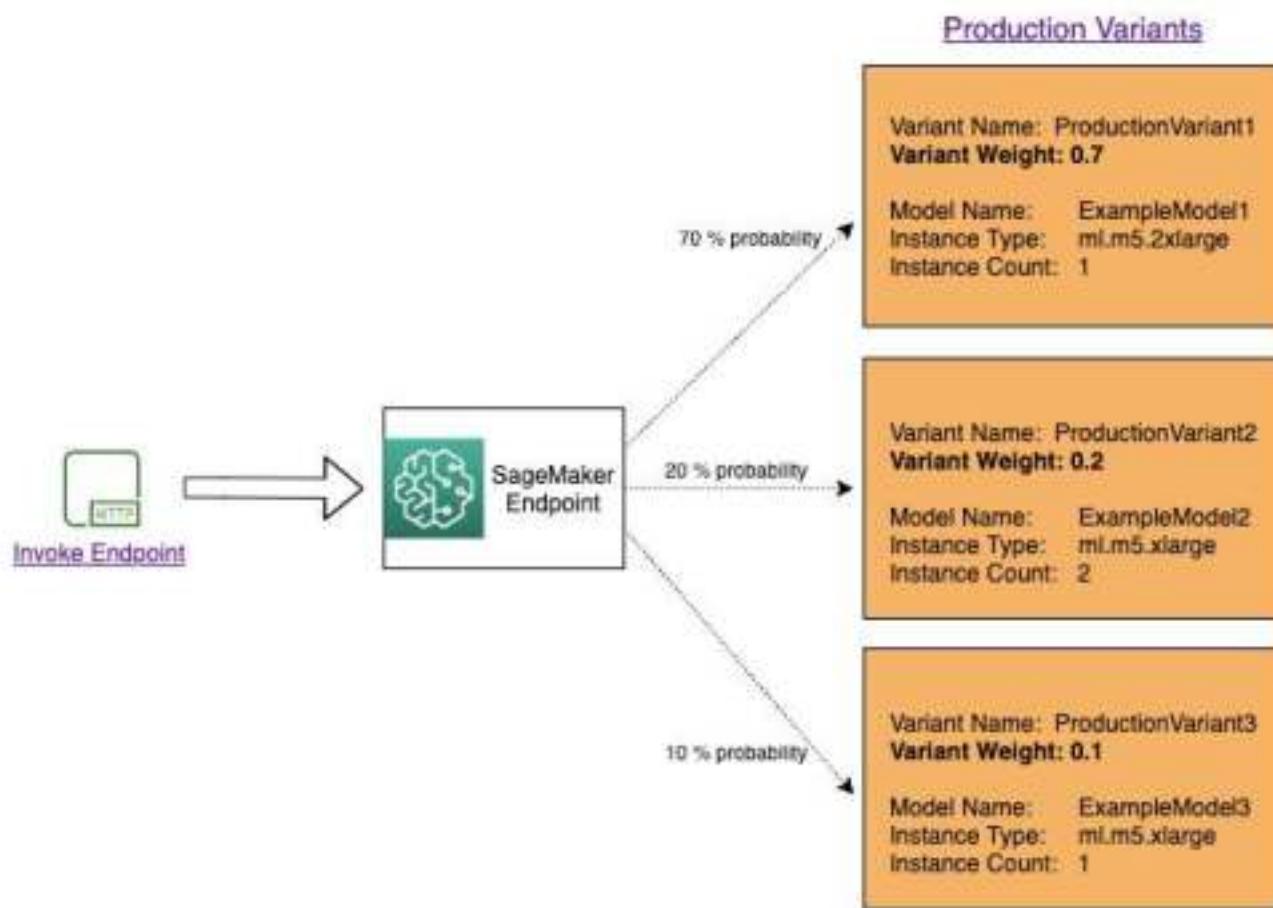

Amazon SageMaker enables you to test multiple models or model versions behind the same endpoint using production variants. Each production variant identifies a machine learning (ML) model and the resources deployed for hosting the model. By using production variants, you can test ML models that have been trained using different datasets, trained using different algorithms and ML frameworks, or are deployed to different instance type, or any combination of all of these. You can distribute endpoint invocation requests across multiple production variants by providing the traffic distribution for each variant, or you can invoke a specific variant directly for each request. In this topic, we look at both methods for testing ML models.

## Topics

- [Test models by specifying traffic distribution \(p. 1947\)](#)
- [Test models by invoking specific variants \(p. 1948\)](#)
- [Model A/B test example \(p. 1949\)](#)

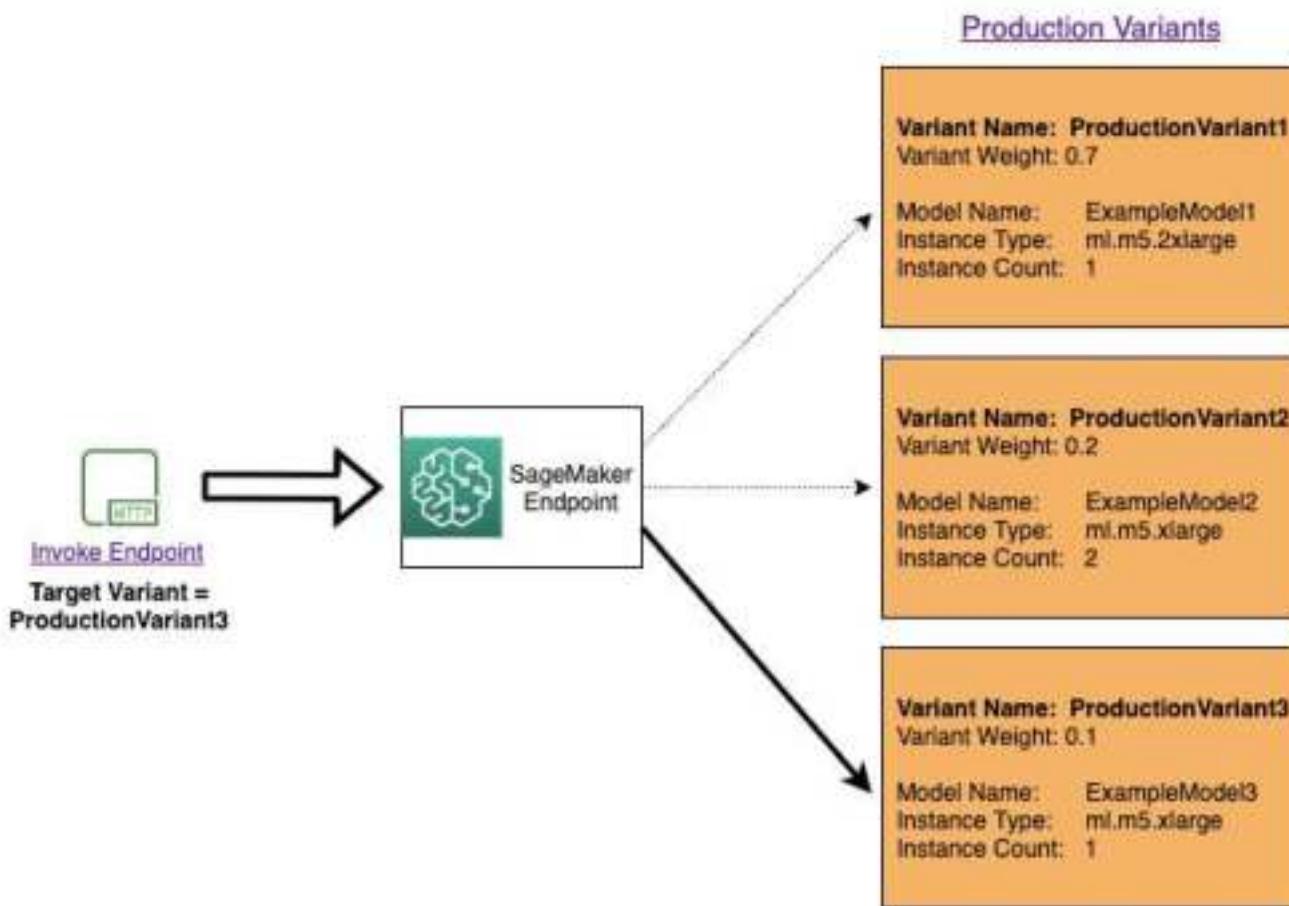

## Test models by specifying traffic distribution

To test multiple models by distributing traffic between them, specify the percentage of the traffic that gets routed to each model by specifying the weight for each production variant in the endpoint configuration. For information, see [CreateEndpointConfig](#). The following diagram shows how this works in more detail.

## Test models by invoking specific variants

To test multiple models by invoking specific models for each request, specify the specific version of the model you want to invoke by providing a value for the `TargetVariant` parameter when you call [InvokeEndpoint](#). SageMaker ensures that the request is processed by the production variant you specify. If you have already provided traffic distribution and specify a value for the `TargetVariant` parameter, the targeted routing overrides the random traffic distribution. The following diagram shows how this works in more detail.

## Model A/B test example

The following example shows how to perform A/B model testing. For a sample notebook that implements this example, see ["A/B Testing ML models in production."](#)

### Step 1: Create and deploy models

First, we define where our models are located in Amazon S3. These locations are used when we deploy our models in subsequent steps:

```
model_url = f"s3://{path_to_model_1}"
model_url2 = f"s3://{path_to_model_2}"
```

Next, we create the model objects with the image and model data. These model objects are used to deploy production variants on an endpoint. The models are developed by training ML models on different data sets, different algorithms or ML frameworks, and different hyperparameters:

```
from sagemaker.amazon.amazon_estimator import get_image_uri
model_name = f"DEMO-xgb-churn-pred-{datetime.now():%Y-%m-%d-%H-%M-%S}"
model_name2 = f"DEMO-xgb-churn-pred2-{datetime.now():%Y-%m-%d-%H-%M-%S}"
```

```

image_uri = get_image_uri(boto3.Session().region_name, 'xgboost', '0.90-1')
image_uri2 = get_image_uri(boto3.Session().region_name, 'xgboost', '0.90-2')

sm_session.create_model(name=model_name, role=role, container_defs={
    'Image': image_uri,
    'ModelDataUrl': model_url
})

sm_session.create_model(name=model_name2, role=role, container_defs={
    'Image': image_uri2,
    'ModelDataUrl': model_url2
})

```

We now create two production variants, each with its own different model and resource requirements (instance type and counts). This enables you to also test models on different instance types.

We set an initial\_weight of 1 for both variants. This means that 50% of requests go to Variant1, and the remaining 50% of requests to Variant2. The sum of weights across both variants is 2 and each variant has weight assignment of 1. This means that each variant receives 1/2, or 50%, of the total traffic.

```

from sagemaker.session import production_variant

variant1 = production_variant(model_name=model_name,
                               instance_type="ml.m5.xlarge",
                               initial_instance_count=1,
                               variant_name='Variant1',
                               initial_weight=1)

variant2 = production_variant(model_name=model_name2,
                               instance_type="ml.m5.xlarge",
                               initial_instance_count=1,
                               variant_name='Variant2',
                               initial_weight=1)

```

Finally we're ready to deploy these production variants on a SageMaker endpoint.

```

endpoint_name = f"DEMO-xgb-churn-pred-{datetime.now():%Y-%m-%d-%H-%M-%S}"
print(f"EndpointName={endpoint_name}")

sm_session.endpoint_from_production_variants(
    name=endpoint_name,
    production_variants=[variant1, variant2]
)

```

## Step 2: Invoke the deployed models

Now we send requests to this endpoint to get inferences in real time. We use both traffic distribution and direct targeting.

First, we use traffic distribution that we configured in the previous step. Each inference response contains the name of the production variant that processes the request, so we can see that traffic to the two production variants is roughly equal.

```

# get a subset of test data for a quick test
!tail -120 test_data/test-dataset-input-cols.csv > test_data/
test_sample_tail_input_cols.csv
print(f"Sending test traffic to the endpoint {endpoint_name}. \nPlease wait...")

```

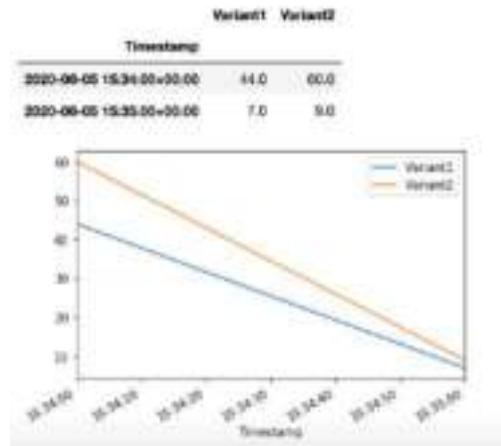

```

with open('test_data/test_sample_tail_input_cols.csv', 'r') as f:
    for row in f:
        print(".", end="", flush=True)
        payload = row.rstrip('\n')
        sm_runtime.invoke_endpoint(EndpointName=endpoint_name,
                                    ContentType="text/csv",
                                    Body=payload)
        time.sleep(0.5)

print("Done!")

```

SageMaker emits metrics such as Latency and Invocations for each variant in Amazon CloudWatch. For a complete list of metrics that SageMaker emits, see [Monitor Amazon SageMaker with Amazon CloudWatch \(p. 2523\)](#). Let's query CloudWatch to get the number of invocations per variant, to show how invocations are split across variants by default:

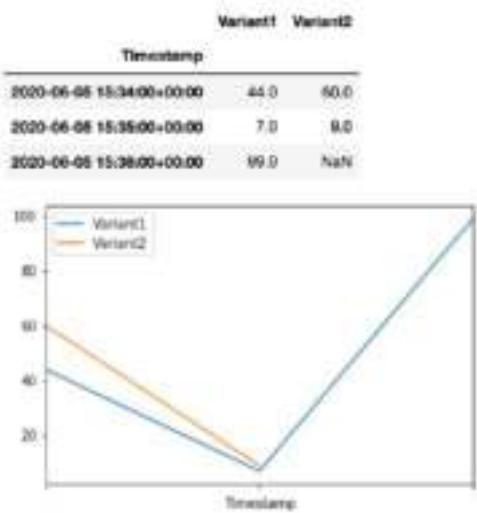

Now let's invoke a specific version of the model by specifying `Variant1` as the `TargetVariant` in the call to `invoke_endpoint`.

```

print(f"Sending test traffic to the endpoint {endpoint_name}. \nPlease wait...")
with open('test_data/test_sample_tail_input_cols.csv', 'r') as f:
    for row in f:
        print(".", end="", flush=True)
        payload = row.rstrip('\n')
        sm_runtime.invoke_endpoint(EndpointName=endpoint_name,
                                    ContentType="text/csv",
                                    Body=payload,
                                    *TargetVariant="Variant1") # Notice the new parameter
        time.sleep(0.5)

```

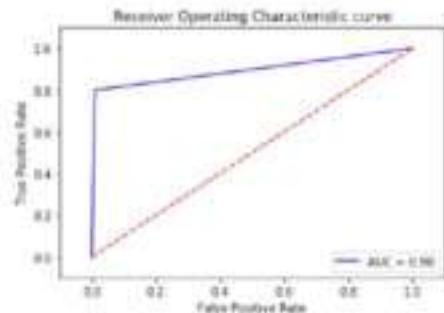

To confirm that all new invocations were processed by `Variant1`, we can query CloudWatch to get the number of invocations per variant. We see that for the most recent invocations (latest timestamp), all requests were processed by `Variant1`, as we had specified. There were no invocations made for `Variant2`.

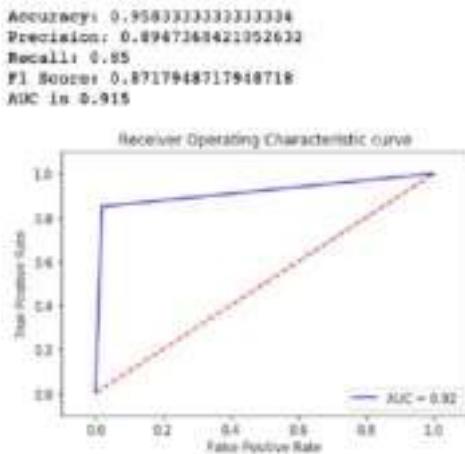

## Step 3: Evaluate model performance

To see which model version performs better, let's evaluate the accuracy, precision, recall, F1 score, and Receiver operating characteristic/Area under the curve for each variant. First, let's look at these metrics for Variant1:

```
Accuracy: 0.9533333333333334
Precision: 0.8111764705882751
Recall: 0.8
F1 Score: 0.8666666666666667
AUC is 0.895
```

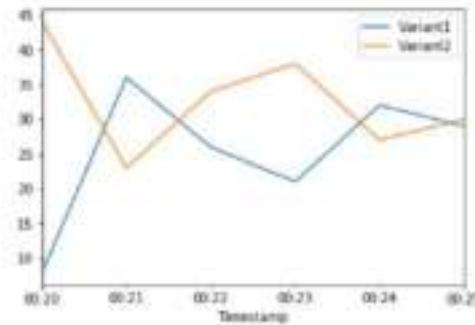

Now let's look at the metrics for Variant2:

For most of our defined metrics, Variant2 is performing better, so this is the one that we want to use in production.

## Step 4: Increase traffic to the best model

Now that we have determined that Variant2 performs better than Variant1, we shift more traffic to it. We can continue to use `TargetVariant` to invoke a specific model variant, but a simpler approach is to update the weights assigned to each variant by calling [UpdateEndpointWeightsAndCapacities](#). This changes the traffic distribution to your production variants without requiring updates to your endpoint. Recall from the setup section that we set variant weights to split traffic 50/50. The CloudWatch metrics for the total invocations for each variant below show us the invocation patterns for each variant:

Now we shift 75% of the traffic to Variant2 by assigning new weights to each variant using `UpdateEndpointWeightsAndCapacities`. SageMaker now sends 75% of the inference requests to Variant2 and remaining 25% of requests to Variant1.

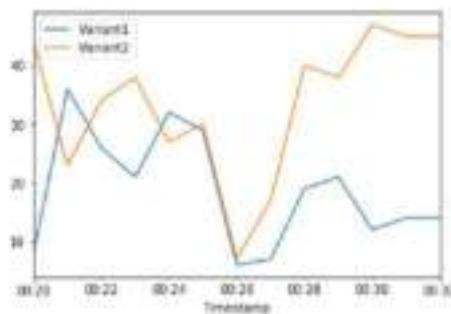

```

sm.update_endpoint_weights_and_capacities(
    EndpointName=endpoint_name,
    DesiredWeightsAndCapacities=[
        {
            "DesiredWeight": 25,
            "VariantName": variant1["VariantName"]
        },
        {
            "DesiredWeight": 75,
            "VariantName": variant2["VariantName"]
        }
    ]
)

```

)

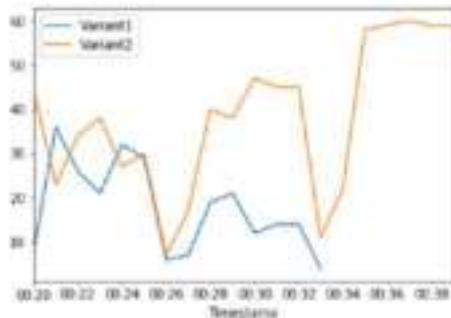

The CloudWatch metrics for total invocations for each variant shows us higher invocations for Variant2 than for Variant1:

We can continue to monitor our metrics, and when we're satisfied with a variant's performance, we can route 100% of the traffic to that variant. We use `UpdateEndpointWeightsAndCapacities` to update the traffic assignments for the variants. The weight for Variant1 is set to 0 and the weight for Variant2 is set to 1. SageMaker now sends 100% of all inference requests to Variant2.

```
sm.update_endpoint_weights_and_capacities(  
    EndpointName=endpoint_name,  
    DesiredWeightsAndCapacities=[  
        {  
            "DesiredWeight": 0,  
            "VariantName": variant1["VariantName"]  
        },  
        {  
            "DesiredWeight": 1,  
            "VariantName": variant2["VariantName"]  
        }  
    ]  
)
```

The CloudWatch metrics for the total invocations for each variant show that all inference requests are being processed by Variant2 and there are no inference requests processed by Variant1.

You can now safely update your endpoint and delete Variant1 from your endpoint. You can also continue testing new models in production by adding new variants to your endpoint and following steps 2 - 4.

# Troubleshoot Amazon SageMaker Model Deployments

If you encounter an issue when deploying machine learning models in Amazon SageMaker, see the following guidance.

## Topics

- [Detection Errors in the Active CPU Count \(p. 1955\)](#)

## Detection Errors in the Active CPU Count

If you deploy a SageMaker model with a Linux Java Virtual Machine (JVM), you might encounter detection errors that prevent using available CPU resources. This issue affects some JVMs that support Java 8 and Java 9, and most that support Java 10 and Java 11. These JVMs implement a mechanism that detects and handles the CPU count and the maximum memory available when running a model in a Docker container, and, more generally, within Linux `taskset` commands or control groups (`cgroups`). SageMaker deployments take advantage of some of the settings that the JVM uses for managing these resources. Currently, this causes the container to incorrectly detect the number of available CPUs.

SageMaker doesn't limit access to CPUs on an instance. However, the JVM might detect the CPU count as 1 when more CPUs are available for the container. As a result, the JVM adjusts all of its internal settings to run as if only 1 CPU core is available. These settings affect garbage collection, locks, compiler threads, and other JVM internals that negatively affect the concurrency, throughput, and latency of the container.

For an example of the misdetection, in a container configured for SageMaker that is deployed with a JVM that is based on Java8\_191 and that has four available CPUs on the instance, run the following command to start your JVM:

```
java -XX:+UnlockDiagnosticVMOptions -XX:+PrintActiveCpus -version
```

This generates the following output:

```
active_processor_count: sched_getaffinity processor count: 4
active_processor_count: determined by OSContainer: 1
active_processor_count: sched_getaffinity processor count: 4
active_processor_count: determined by OSContainer: 1
active_processor_count: sched_getaffinity processor count: 4
active_processor_count: determined by OSContainer: 1
active_processor_count: sched_getaffinity processor count: 4
active_processor_count: determined by OSContainer: 1
openjdk version "1.8.0_191"
OpenJDK Runtime Environment (build 1.8.0_191-8u191-b12-2ubuntu0.16.04.1-b12)
OpenJDK 64-Bit Server VM (build 25.191-b12, mixed mode)
```

Many of the JVMs affected by this issue have an option to disable this behavior and reestablish full access to all of the CPUs on the instance. Disable the unwanted behavior and establish full access to all instance CPUs by including the `-XX:-UseContainerSupport` parameter when starting Java applications. For example, run the `java` command to start your JVM as follows:

```
java -XX:-UseContainerSupport -XX:+UnlockDiagnosticVMOptions -XX:+PrintActiveCpus -version
```

This generates the following output:

```
active_processor_count: sched_getaffinity processor count: 4
openjdk version "1.8.0_191"
OpenJDK Runtime Environment (build 1.8.0_191-8u191-b12-2ubuntu0.16.04.1-b12)
OpenJDK 64-Bit Server VM (build 25.191-b12, mixed mode)
```

Check whether the JVM used in your container supports the `-XX:-UseContainerSupport` parameter. If it does, always pass the parameter when you start your JVM. This provides access to all of the CPUs in your instances.

You might also encounter this issue when indirectly using a JVM in SageMaker containers. For example, when using a JVM to support SparkML Scala. The `-XX:-UseContainerSupport` parameter also affects the output returned by the `Java Runtime.getRuntime().availableProcessors()` API .

## Deployment Best Practices

This topic provides guidance on best practices for deploying machine learning models in Amazon SageMaker.

### Deploy Multiple Instances Across Availability Zones

**Create robust endpoints when hosting your model.** SageMaker endpoints can help protect your application from [Availability Zone](#) outages and instance failures. If an outage occurs or an instance fails, SageMaker automatically attempts to distribute your instances across Availability Zones. For this reason, we strongly recommended that you deploy multiple instances for each production endpoint.

If you are using an [Amazon Virtual Private Cloud \(VPC\)](#), configure the VPC with at least two [Subnets](#), each in a different Availability Zone. If an outage occurs or an instance fails, Amazon SageMaker automatically attempts to distribute your instances across Availability Zones.

In general, to achieve more reliable performance, use more small [Instance Types](#) in different Availability Zones to host your endpoints.

## Amazon SageMaker Model Monitor

Amazon SageMaker Model Monitor continuously monitors the quality of Amazon SageMaker machine learning models in production. With Model Monitor, you can set alerts that notify you when there are deviations in the model quality. Early and proactive detection of these deviations enables you to take corrective actions, such as retraining models, auditing upstream systems, or fixing quality issues without having to monitor models manually or build additional tooling. You can use Model Monitor prebuilt monitoring capabilities that do not require coding. You also have the flexibility to monitor models by coding to provide custom analysis.

Model Monitor provides the following types of monitoring:

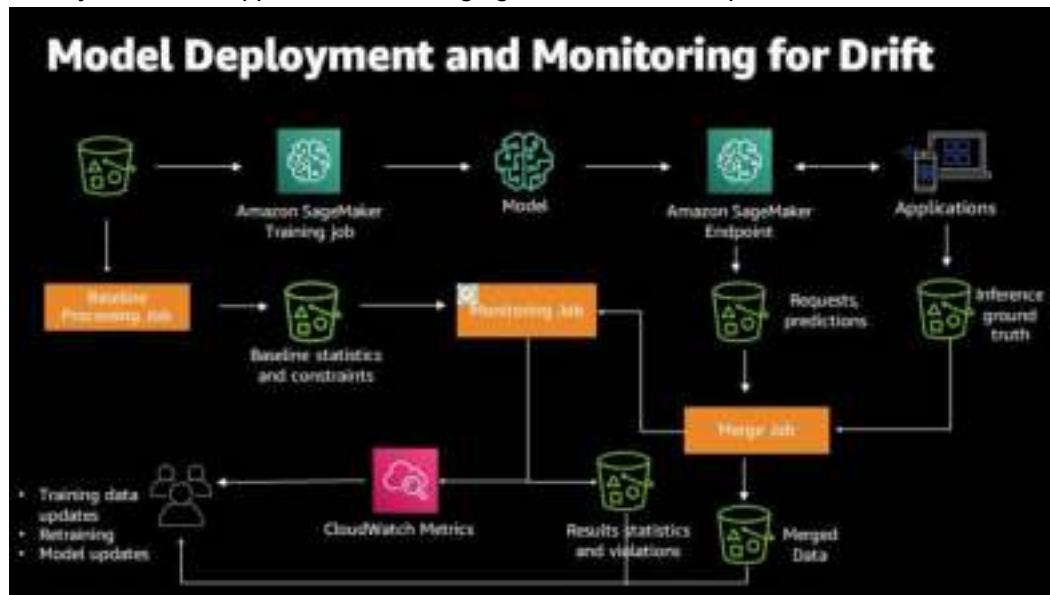

- [Monitor Data Quality \(p. 1958\)](#) - Monitor drift in data quality.
- [Monitor Model Quality \(p. 1963\)](#) - Monitor drift in model quality metrics, such as accuracy.
- [Monitor Bias Drift for Models in Production \(p. 1970\)](#) - Monitor bias in your model's predictions.
- [Monitor Feature Attribution Drift for Models in Production \(p. 1973\)](#) - Monitor drift in feature attribution.

## Topics

## How Model Monitor Works

Amazon SageMaker Model Monitor automatically monitors machine learning (ML) models in production and notifies you when quality issues arise. Model Monitor uses rules to detect drift in your models and alerts you when it happens. The following figure shows how this process works.

To enable model monitoring, you take the following steps, which follow the path of the data through the various data collection, monitoring, and analysis processes:

- Enable the endpoint to capture data from incoming requests to a trained ML model and the resulting model predictions.
- Create a baseline from the dataset that was used to train the model. The baseline computes metrics and suggests constraints for the metrics. Real-time predictions from your model are compared to the constraints, and are reported as violations if they are outside the constrained values.
- Create a monitoring schedule specifying what data to collect, how often to collect it, how to analyze it, and which reports to produce.
- Inspect the reports, which compare the latest data with the baseline, and watch for any violations reported and for metrics and notifications from Amazon CloudWatch.

## Notes

- Model Monitor currently supports only tabular data.
- Model Monitor currently supports only endpoints that host a single model and does not support monitoring multi-model endpoints. For information on using multi-model endpoints, see [Host Multiple Models with Multi-Model Endpoints \(p. 1895\)](#).
- Model Monitor supports monitoring inference pipelines, but capturing and analyzing data is done for the entire pipeline, not for individual containers in the pipeline.
- To prevent impact to inference requests, Data Capture stops capturing requests at high levels of disk usage. It is recommended you keep your disk utilization below 75% in order to ensure data capture continues capturing requests.
- If you launch SageMaker Studio in a custom Amazon VPC, you need to create VPC endpoints to enable Model Monitor to communicate with Amazon S3 and CloudWatch. For information about VPC endpoints, see [VPC endpoints](#) in the *Amazon Virtual Private Cloud User Guide*. For information about launching SageMaker Studio in a custom VPC, see [Connect SageMaker Studio Notebooks to Resources in a VPC \(p. 2491\)](#).

## Model Monitor Sample Notebooks

For a sample notebook that takes you through the full end-to-end workflow for Model Monitor, see the [Introduction to Amazon SageMaker Model Monitor](#).

For a sample notebook that visualizes the statistics.json file for a selected execution in a monitoring schedule, see the [Model Monitor Visualization](#).

For instructions that show you how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see [Use Amazon SageMaker Notebook Instances \(p. 120\)](#). After you have created a notebook instance and opened it, choose the **SageMaker Examples** tab to see a list of all the SageMaker samples. To open a notebook, choose the notebook's **Use** tab and choose **Create copy**.

## Monitor Data Quality

Data quality monitoring automatically monitors machine learning (ML) models in production and notifies you when data quality issues arise. ML models in production have to make predictions on real-life data that is not carefully curated like most training datasets. If the statistical nature of the data that your model receives while in production drifts away from the nature of the baseline data it was trained on, the model begins to lose accuracy in its predictions. Amazon SageMaker Model Monitor uses rules to detect data drift and alerts you when it happens. To monitor data quality, follow these steps:

- Enable data capture. This captures inference input and output from a real-time inference endpoint and stores the data in Amazon S3. For more information, see [Capture Data \(p. 1977\)](#).
- Create a baseline. In this step, you run a baseline job that analyzes an input dataset that you provide. The baseline computes baseline schema constraints and statistics for each feature using [Deequ](#), an open source library built on Apache Spark, which is used to measure data quality in large datasets. For more information, see [Create a Baseline \(p. 1959\)](#).
- Define and schedule data quality monitoring jobs. For more information, see [Schedule Monitoring Jobs \(p. 1979\)](#).
- View data quality metrics. For more information, see [Schema for Statistics \(statistics.json file\) \(p. 1960\)](#).
- Integrate data quality monitoring with Amazon CloudWatch. For more information, see [CloudWatch Metrics \(p. 1961\)](#).
- Interpret the results of a monitoring job. For more information, see [Interpret Results \(p. 1982\)](#).
- Use SageMaker Studio to enable data quality monitoring and visualize results. For more information, see [Visualize Results in Amazon SageMaker Studio \(p. 1984\)](#).

**Note**

Amazon SageMaker Model Monitor currently supports only tabular data.

**Topics**

- [Create a Baseline \(p. 1959\)](#)
- [Schema for Statistics \(statistics.json file\) \(p. 1960\)](#)

- [Schema for Violations \(constraint\\_violations.json file\) \(p. 1962\)](#)

## Create a Baseline

The baseline calculations of statistics and constraints are needed as a standard against which data drift and other data quality issues can be detected. Model Monitor provides a built-in container that provides the ability to suggest the constraints automatically for CSV and flat JSON input. This *sagemaker-model-monitor-analyzer* container also provides you with a range of model monitoring capabilities, including constraint validation against a baseline, and emitting Amazon CloudWatch metrics. This container is based on Spark and is built with [Deequ](#). All column names in your baseline dataset must be compliant with Spark. For column names, use only lowercase characters, and `_` as the only special character.

The training dataset that you used to trained the model is usually a good baseline dataset. The training dataset data schema and the inference dataset schema should exactly match (the number and order of the features). Note that the prediction/output columns are assumed to be the first columns in the training dataset. From the training dataset, you can ask SageMaker to suggest a set of baseline constraints and generate descriptive statistics to explore the data. For this example, upload the training dataset that was used to train the pretrained model included in this example. If you already stored the training dataset in Amazon S3, you can point to it directly.

### To Create a baseline from a training dataset

When you have your training data ready and stored in Amazon S3, start a baseline processing job with `DefaultModelMonitor.suggest_baseline()` using the [Amazon SageMaker Python SDK](#). This uses an [Amazon SageMaker Model Monitor Prebuilt Container \(p. 1981\)](#) that generates baseline statistics and suggests baseline constraints for the dataset and writes them to the `output_s3_uri` location that you specify.

```
from sagemaker.model_monitor import DefaultModelMonitor
from sagemaker.model_monitor.dataset_format import DatasetFormat

my_default_monitor = DefaultModelMonitor(
    role=role,
    instance_count=1,
    instance_type='ml.m5.xlarge',
    volume_size_in_gb=20,
    max_runtime_in_seconds=3600,
)

my_default_monitor.suggest_baseline(
    baseline_dataset=baseline_data_uri+'/training-dataset-with-header.csv',
    dataset_format=DatasetFormat.csv(header=True),
    output_s3_uri=baseline_results_uri,
    wait=True
)
```

**Note**

If you provide the feature/column names in the training dataset as the first row and set the `header=True` option as shown in the previous code sample, SageMaker uses the feature name in the constraints and statistics file.

The baseline statistics for the dataset are contained in the `statistics.json` file and the suggested baseline constraints are contained in the `constraints.json` file in the location you specify with `output_s3_uri`.

### Output Files for Tabular Dataset Statistics and Constraints

File Name	Description
<code>statistics.json</code>	This file is expected to have columnar statistics for each feature in the dataset that is analyzed. For more information about the schema for this file, see <a href="#">Schema for Statistics (statistics.json file) (p. 1995)</a> .
<code>constraints.json</code>	This file is expected to have the constraints on the features observed. For more information about the schema for this file, see <a href="#">Schema for Constraints (constraints.json file) (p. 1997)</a> .

The [Amazon SageMaker Python SDK](#) provides convenience functions described to generate the baseline statistics and constraints. But if you want to call processing job directly for this purpose instead, you need to set the `Environment` map as shown in the following example:

```
"Environment": {
    "dataset_format": "{\"csv\": { \"header\": true}}",
    "dataset_source": "/opt/ml/processing/sm_input",
    "output_path": "/opt/ml/processing/sm_output",
    "publish_cloudwatch_metrics": "Disabled",
}
```

### Schema for Statistics (statistics.json file)

Amazon SageMaker Model Monitor prebuilt container computes per column/feature statistics. The statistics are calculated for the baseline dataset and also for the current dataset that is being analyzed.

```
{
    "version": 0,
    # dataset level stats
    "dataset": {
        "item_count": number
    },
    # feature level stats
    "features": [
        {
            "name": "feature-name",
            "inferred_type": "Fractional" | "Integral",

                            {
                                "lower_bound": number,

```

```

        "upper_bound": number,
        "count": number
    }
],
"sketch": {
    "parameters": {
        "c": number,
        "k": number
    },
    "data": [
        [
            [
                num,
                num,
                num,
                num
            ],
            [
                num,
                num
            ][
                num,
                num
            ]
        ]
    }
} #sketch
} #KLL
} #distribution
} #num_stats
},
{
    "name": "feature-name",
    "inferred_type": "String",
    "string_statistics": {
        "common": {
            "num_present": number,
            "num_missing": number
        },
        "distinct_count": number,
        "distribution": {
            "categorical": {
                "buckets": [
                    {
                        "value": "string",
                        "count": number
                    }
                ]
            }
        }
    },
    "#provision for custom stats"
}
]
}
}

```

Note the following:

- The prebuilt containers compute [KLL sketch](#), which is a compact quantiles sketch.
- By default, we materialize the distribution in 10 buckets. This is not currently configurable.

## CloudWatch Metrics

You can use the built-in Amazon SageMaker Model Monitor container for CloudWatch metrics. When the `emit_metrics` option is `Enabled` in the baseline constraints file, SageMaker emits these metrics

for each feature/column observed in the dataset in the `/aws/sagemaker/Endpoints/data-metric` namespace with `EndpointName` and `ScheduleName` dimensions.

For numerical fields, the built-in container emits the following CloudWatch metrics:

- Metric: Max → query for `MetricName: feature_data_{feature_name}`, Stat: Max
- Metric: Min → query for `MetricName: feature_data_{feature_name}`, Stat: Min
- Metric: Sum → query for `MetricName: feature_data_{feature_name}`, Stat: Sum
- Metric: SampleCount → query for `MetricName: feature_data_{feature_name}`, Stat: SampleCount
- Metric: Average → query for `MetricName: feature_data_{feature_name}`, Stat: Average

For both numerical and string fields, the built-in container emits the following CloudWatch metrics:

- Metric: Completeness → query for `MetricName: feature_non_null_{feature_name}`, Stat: Sum
- Metric: Baseline Drift → query for `MetricName: feature_baseline_drift_{feature_name}`, Stat: Sum

## Schema for Violations (constraint\_violations.json file)

The violations file is generated as the output of a `MonitoringExecution`, which lists the results of evaluating the constraints (specified in the `constraints.json` file) against the current dataset that was analyzed. The Amazon SageMaker Model Monitor prebuilt container provides the following violation checks.

```
{
  "violations": [
    {
      "feature_name" : "string",
      "constraint_check_type" :
        "data_type_check",
        | "completeness_check",
        | "baseline_drift_check",
        | "missing_column_check",
        | "extra_column_check",
        | "categorical_values_check"
      "description" : "string"
    }
  ]
}
```

### Types of Violations Monitored

Violation Check Type	Description
<code>data_type_check</code>	If the data types in the current execution are not the same as in the baseline dataset, this violation is flagged.  During the baseline step, the generated constraints suggest the inferred data type for each column. The <code>monitoring_config.datatype_check_threshold</code> parameter can be tuned to adjust the threshold on when it is flagged as a violation.
<code>completeness_check</code>	If the completeness (% of non-null items) observed in the current execution exceeds the

Violation Check Type	Description
	threshold specified in completeness threshold specified per feature, this violation is flagged.
	During the baseline step, the generated constraints suggest a completeness value.
<code>baseline_drift_check</code>	If the calculated distribution distance between the current and the baseline datasets is more than the threshold specified in <code>monitoring_config.comparison_threshold</code> , this violation is flagged.
<code>missing_column_check</code>	If the number of columns in the current dataset is less than the number in the baseline dataset, this violation is flagged.
<code>extra_column_check</code>	If the number of columns in the current dataset is more than the number in the baseline, this violation is flagged.
<code>categorical_values_check</code>	If there are more unknown values in the current dataset than in the baseline dataset, this violation is flagged. This value is dictated by the threshold in <code>monitoring_config.domain_content_threshold</code> .

## Monitor Model Quality

Model quality monitoring jobs monitor the performance of a model by comparing the predictions that the model makes with the actual ground truth labels that the model attempts to predict. To do this, model quality monitoring merges data that is captured from real-time inference with actual labels that you store in an Amazon S3 bucket, and then compares the predictions with the actual labels.

To measure model quality, model monitor uses metrics that depend on the ML problem type. For example, if your model is for a regression problem, one of the metrics evaluated is mean square error (mse). For information about all of the metrics used for the different ML problem types, see [Model Quality Metrics \(p. 1966\)](#).

Model quality monitoring follows the same steps as data quality monitoring, but adds the additional step of merging the actual labels from Amazon S3 with the predictions captured from the real-time inference endpoint. To monitor model quality, follow these steps:

- Enable data capture. This captures inference input and output from a real-time inference endpoint and stores the data in Amazon S3. For more information, see [Capture Data \(p. 1977\)](#).
- Create a baseline. In this step, you run a baseline job that compares predictions from the model with ground truth labels in a baseline dataset. The baseline job automatically creates baseline statistical rules and constraints that define thresholds against which the model performance is evaluated. For more information, see [Create a Model Quality Baseline \(p. 1964\)](#).
- Define and schedule model quality monitoring jobs. For more information, see [Schedule Model Quality Monitoring Jobs \(p. 1965\)](#).
- Ingest ground truth labels that model monitor merges with captured prediction data from real-time inference endpoint. For more information, see [Ingest Ground Truth Labels and Merge Them With Predictions \(p. 1966\)](#).

- Integrate model quality monitoring with Amazon CloudWatch. For more information, see [Model Quality CloudWatch Metrics \(p. 1970\)](#).
- Interpret the results of a monitoring job. For more information, see [Interpret Results \(p. 1982\)](#).
- Use SageMaker Studio to enable model quality monitoring and visualize results. For more information, see [Visualize Results in Amazon SageMaker Studio \(p. 1984\)](#).

## Topics

- [Create a Model Quality Baseline \(p. 1964\)](#)
- [Schedule Model Quality Monitoring Jobs \(p. 1965\)](#)
- [Ingest Ground Truth Labels and Merge Them With Predictions \(p. 1966\)](#)

- [Model Quality CloudWatch Metrics \(p. 1970\)](#)

## Create a Model Quality Baseline

Create a baseline job that compares your model predictions with ground truth labels in a baseline dataset that you have stored in Amazon S3. Typically, you use a training dataset as the baseline dataset. The baseline job calculates metrics for the model and suggests constraints to use to monitor model quality drift.

To create a baseline job, you need to have a dataset that contains predictions from your model along with labels that represent the ground truth for your data.

To create a baseline job use the `ModelQualityMonitor` class provided by the SageMaker Python SDK, and complete the following steps.

### To create a model quality baseline job

1. First, create an instance of the `ModelQualityMonitor` class. The following code snippet shows how to do this.

```
from sagemaker import get_execution_role, session, Session
from sagemaker.model_monitor import ModelQualityMonitor

role = get_execution_role()
session = Session()

model_quality_monitor = ModelQualityMonitor(
    role=role,
    instance_count=1,
    instance_type='ml.m5.xlarge',
    volume_size_in_gb=20,
    max_runtime_in_seconds=1800,
    sagemaker_session=session
)
```

2. Now call the `suggest_baseline` method of the `ModelQualityMonitor` object to run a baseline job. The following code snippet assumes that you have a baseline dataset that contains both predictions and labels stored in Amazon S3.

```
baseline_job_name = "MyBaselineJob"
job = model_quality_monitor.suggest_baseline(
    job_name=baseline_job_name,
    baseline_dataset=baseline_dataset_uri, # The S3 location of the validation dataset.
    dataset_format=DatasetFormat.csv(header=True),
```

```
        output_s3_uri = baseline_results_uri, # The S3 location to store the results.
        problem_type='BinaryClassification',
        inference_attribute= "prediction", # The column in the dataset that contains
predictions.
        probability_attribute= "probability", # The column in the dataset that contains
probabilities.
        ground_truth_attribute= "label" # The column in the dataset that contains ground
truth labels.
)
job.wait(logs=False)
```

3. After the baseline job finishes, you can see the constraints that the job generated. First, get the results of the baseline job by calling the `latest_baselining_job` method of the `ModelQualityMonitor` object.

```
baseline_job = model_quality_monitor.latest_baselining_job
```

4. The baseline job suggests constraints, which are thresholds for metrics that model monitor measures. If a metric goes beyond the suggested threshold, Model Monitor reports a violation. To view the constraints that the baseline job generated, call the `suggested_constraints` method of the baseline job. The following code snippet loads the constraints for a binary classification model into a Pandas dataframe.

```
import pandas as pd
pd.DataFrame(baseline_job.suggested_constraints().body_dict["binary_classification_constraints"]).T
```

We recommend that you view the generated constraints and modify them as necessary before using them for monitoring. For example, if a constraint is too aggressive, you might get more alerts for violations than you want.

5. When you are satisfied with the constraints, pass them as the `constraints` parameter when you create a monitoring schedule. For more information, see [Schedule Model Quality Monitoring Jobs \(p. 1965\)](#).

The suggested baseline constraints are contained in the `constraints.json` file in the location you specify with `output_s3_uri`. For information about the schema for this file in the [Schema for Constraints \(constraints.json file\) \(p. 1997\)](#).

## Schedule Model Quality Monitoring Jobs

For general information about scheduling monitoring jobs, see [the section called “Schedule Monitoring Jobs” \(p. 1979\)](#). For model quality monitoring, you also have to consider the fact that the availability of ground truth labels might be delayed.

To address this, use offsets. Model quality jobs include `StartOffset` and `EndOffset`, which are fields of the `ModelQualityJobInput` parameter of the `create_model_quality_job_definition` method that work as follows:

- `StartOffset` - If specified, jobs subtract this time from the start time.
- `EndOffset` - If specified, jobs subtract this time from the end time.

The format of the offsets are, for example, `-P7H`, where `7H` is 7 hours. You can use `-P#H` or `-P#D`, where `H=hours`, `D=days`, and `M=minutes`, and `#` is the number.

For example, if your ground truth starts coming in after 1 day, but is not complete for a week, set `StartOffset` to `-P8D` and `EndOffset` to `-P1D`. Then, if you schedule a job to run at `2020-01-09T13:00`, it analyzes data from between `2020-01-01T13:00` and `2020-01-08T13:00`.

### Important

The schedule cadence should be such that one execution finishes before the next execution starts, which allows the ground truth merge job and monitoring job from the execution to complete. The maximum runtime of an execution is divided between the two jobs, so for an hourly model quality monitoring job, the value of `MaxRuntimeInSeconds` specified as part of `StoppingCondition` should be no more than 1800.

## Ingest Ground Truth Labels and Merge Them With Predictions

Model quality monitoring compares the predictions your model makes with ground truth labels to measure the quality of the model. For this to work, you periodically label data captured by your endpoint and upload it to Amazon S3.

To match ground truth labels with captured prediction data, there must be a unique identifier for each record in the dataset. The structure of each record for ground truth data is as follows:

```
{  
    "groundTruthData": {  
        "data": "1",  
        "encoding": "CSV" # only CSV supported at launch, we assume "data" only consists of  
        "label"  
    },  
    "eventMetadata": {  
        "eventId": "aaaa-bbbb-cccc"  
    },  
    "eventVersion": "0"  
}
```

In the `groundTruthData` structure, `eventId` can be one of the following:

- `eventId` – This ID is automatically generated when a user invokes the endpoint.
- `inferenceId` – The caller supplies this ID when they invoke the endpoint.

If `inferenceId` is present in captured data records, Model Monitor uses it to merge captured data with ground truth records. You are responsible for making sure that the `inferenceId` in the ground truth records match the `inferenceId` in the captured records. If `inferenceId` is not present in captured data, model monitor uses `eventId` from the captured data records to match them with a ground truth record.

You must upload ground truth data to an Amazon S3 bucket that has the same path format as captured data, which is of the following form:

```
s3://bucket/prefixyyyy/mm/dd/hh
```

The date in this path is the date when the ground truth label is collected, and does not have to match the date when the inference was generated.

After you create and upload the ground truth labels, include the location of the labels as a parameter when you create the monitoring job. If you are using Amazon SDK for Python (Boto3), do this by specifying the location of ground truth labels as the `S3Uri` field of the `GroundTruthS3Input` parameter in a call to the `create_model_quality_job_definition` method. If you are using the SageMaker Python SDK, specify the location of the ground truth labels as the `ground_truth_input` parameter in the call to the `create_monitoring_schedule` of the `ModelQualityMonitor` object.

## Model Quality Metrics

Model quality monitoring jobs compute different metrics depending on the ML problem type. The following sections list the metrics analyzed for each ML problem type.

### Note

Standard deviation for metrics are provided only when at least 200 samples are available. Model Monitor computes standard deviation by randomly sampling 80% of the data 5 times, computing the metric, and taking the standard deviation for those results.

## Regression Metrics

The following shows an example of the metrics that model quality monitor computes for a regression problem.

```
"regression_metrics" : {
    "mae" : {
        "value" : 0.3711832061068702,
        "standard_deviation" : 0.0037566388129940394
    },
    "mse" : {
        "value" : 0.3711832061068702,
        "standard_deviation" : 0.0037566388129940524
    },
    "rmse" : {
        "value" : 0.609248066149471,
        "standard_deviation" : 0.003079253267651125
    },
    "r2" : {
        "value" : -1.3766111872212665,
        "standard_deviation" : 0.022653980022771227
    }
}
```

## Binary Classification Metrics

The following shows an example of the metrics that model quality monitor computes for a binary classification problem.

```
"binary_classification_metrics" : {
    "confusion_matrix" : {
        "0" : {
            "0" : 1,
            "1" : 2
        },
        "1" : {
            "0" : 0,
            "1" : 1
        }
    },
    "recall" : {
        "value" : 1.0,
        "standard_deviation" : "NaN"
    },
    "precision" : {
        "value" : 0.3333333333333333,
        "standard_deviation" : "NaN"
    },

    }
}
```

## Model Quality CloudWatch Metrics

If you set the value of the `enable_cloudwatch_metrics` to `True` when you create the monitoring schedule, model quality monitoring jobs send all metrics to Amazon CloudWatch.

Model quality metrics appear in the `aws/sagemaker/Endpoints/model-metrics` namespace. For a list of the metrics that are emitted, see [Model Quality Metrics \(p. 1966\)](#).

You can use CloudWatch metrics to create an alarm when a specific metric doesn't meet the threshold you specify. For instructions about how to create CloudWatch alarms, see [Create a CloudWatch Alarm Based on a Static Threshold](#) in the *Amazon CloudWatch User Guide*.

## Monitor Bias Drift for Models in Production

Amazon SageMaker Clarify bias monitoring helps data scientists and ML engineers monitor predictions for bias on a regular basis. As the model is monitored, customers can view exportable reports and graphs detailing bias in SageMaker Studio and configure alerts in Amazon CloudWatch to receive notifications if bias beyond a certain threshold is detected. Bias can be introduced or exacerbated in deployed ML models when the training data differs from the data that the model sees during deployment (that is, the live data). These kinds of changes in the live data distribution might be temporary (for example, due to some short-lived, real-world events) or permanent. In either case, it might be important to detect these changes. For example, the outputs of a model for predicting home prices can become biased if the mortgage rates used to train the model differ from current, real-world mortgage rates. With bias detection capabilities in Model Monitor, when SageMaker detects bias beyond a certain threshold, it automatically generates metrics that you can view in SageMaker Studio and through Amazon CloudWatch alerts.

In general, measuring bias only during the train-and-deploy phase might not be sufficient. It is possible that after the model has been deployed, the distribution of the data that the deployed model sees (that is, the live data) is different from data distribution in the training dataset. This change might introduce bias in a model over time. The change in the live data distribution might be temporary (for example, due to some short-lived behavior like the holiday season) or permanent. In either case, it might be important to detect these changes and take steps to reduce the bias when appropriate.

To detect these changes, SageMaker Clarify provides functionality to monitor the bias metrics of a deployed model continuously and raise automated alerts if the metrics exceed a threshold. For example, consider the DPPL bias metric. Specify an allowed range of values  $A=(a_{\min}, a_{\max})$ , for instance an interval of  $(-0.1, 0.1)$ , that DPPL should belong to during deployment. Any deviation from this range should raise a *bias detected* alert. With SageMaker Clarify, you can perform these checks at regular intervals.

For example, you can set the frequency of the checks to 2 days. This means that SageMaker Clarify computes the DPPL metric on data collected during a 2-day window. In this example,  $D_{\text{win}}$  is the data that the model processed during last 2-day window. An alert is issued if the DPPL value  $b_{\text{win}}$  computed on  $D_{\text{win}}$  falls outside of an allowed range  $A$ . This approach to checking if  $b_{\text{win}}$  is outside of  $A$  can be somewhat noisy.  $D_{\text{win}}$  might consist of very few samples and might not be representative of the live data distribution. The small sample size means that the value of bias  $b_{\text{win}}$  computed over  $D_{\text{win}}$  might not be a very robust estimate. In fact, very high (or low) values of  $b_{\text{win}}$  may be observed purely due to chance. To ensure that the conclusions drawn from the observed data  $D_{\text{win}}$  are statistically significant, SageMaker Clarify makes use of confidence intervals. Specifically, it uses the Normal Bootstrap Interval method to construct an interval  $C=(c_{\min}, c_{\max})$  such that SageMaker Clarify is confident that the true bias value computed over the full live data is contained in  $C$  with high probability. Now, if the confidence interval  $C$  overlaps with the allowed range  $A$ , SageMaker Clarify interprets it as "it is likely that the bias metric value of the live data distribution falls within the allowed range". If  $C$  and  $A$  are disjoint, SageMaker Clarify is confident that the bias metric does not lie in  $A$  and raises an alert.

## Model Monitor Sample Notebook

Amazon SageMaker Clarify provides the following sample notebook that shows how to capture real-time inference data, create a baseline to monitor evolving bias against, and inspect the results:

- [Monitoring bias drift and feature attribution drift Amazon SageMaker Clarify](#) – Use Amazon SageMaker Model Monitor to monitor bias drift and feature attribution drift over time.

This notebook has been verified to run in Amazon SageMaker Studio only. If you need instructions on how to open a notebook in Amazon SageMaker Studio, see [Create or Open an Amazon SageMaker Studio Notebook \(p. 79\)](#). If you're prompted to choose a kernel, choose **Python 3 (Data Science)**. The following topics contain the highlights from the last two steps, and they contain code examples from the example notebook.

### Topics

- [Create a Bias Drift Baseline \(p. 1971\)](#)
- [Schedule Bias Drift Monitoring Jobs \(p. 1972\)](#)
- [Inspect Reports for Data Bias Drift \(p. 1973\)](#)

## Create a Bias Drift Baseline

After you have configured your application to capture real-time inference data, the first task to monitor for bias drift is to create a baseline. This involves configuring the data inputs, which groups are sensitive, how the predictions are captured, and the model and its posttraining bias metrics. Then you need to start the baselining job.

Model bias monitor can detect bias drift of ML models on a regular basis. Similar to the other monitoring types, the standard procedure of creating a model bias monitor is first baselining and then establishing a monitoring schedule.

```
model_bias_monitor = ModelBiasMonitor(  
    role=role,  
    sagemaker_session=sagemaker_session,  
    max_runtime_in_seconds=1800,  
)
```

DataConfig stores information about the dataset to be analyzed (for example, the dataset file), its format (that is, CSV or JSONLines), headers (if any) and label.

```
model_bias_baselining_job_result_uri = f"{baseline_results_uri}/model_bias"  
model_bias_data_config = DataConfig(  
    s3_data_input_path=validation_dataset,  
    s3_output_path=model_bias_baselining_job_result_uri,  
    label=label_header,  
    headers=all_headers,  
    dataset_type=dataset_type,  
)
```

BiasConfig is the configuration of the sensitive groups in the dataset. Typically, bias is measured by computing a metric and comparing it across groups. The group of interest is called the *facet*. For posttraining bias, you should also take the positive label into account.

```
model_bias_config = BiasConfig(
```

```

        label_values_or_threshold=[1],
        facet_name="Account Length",
        facet_values_or_threshold=[100],
    )
)

```

`ModelPredictedLabelConfig` specifies how to extract a predicted label from the model output. In this example, the 0.8 cutoff has been chosen in anticipation that customers will turn over frequently. For more complicated outputs, there are a few more options, like "label" is the index, name, or JSONPath to locate predicted label in endpoint response payload.

```

model_predicted_label_config = ModelPredictedLabelConfig(
    probability_threshold=0.8,
)

```

`ModelConfig` is the configuration related to the model to be used for inferencing. In order to compute posttraining bias metrics, the computation needs to get inferences for the model name provided. To accomplish this, the processing job uses the model to create an ephemeral endpoint (also known as *shadow endpoint*). The processing job deletes the shadow endpoint after the computations are completed. This configuration is also used by the explainability monitor.

```

model_config = ModelConfig(
    model_name=model_name,
    instance_count=endpoint_instance_count,
    instance_type=endpoint_instance_type,
    content_type=dataset_type,
    accept_type=dataset_type,
)

```

Now you can start the baselining job.

```

model_bias_monitor.suggest_baseline(
    model_config=model_config,
    data_config=model_bias_data_config,
    bias_config=model_bias_config,
    model_predicted_label_config=model_predicted_label_config,
)
print(f"ModelBiasMonitor baselining job: {model_bias_monitor.latest_baselining_job_name}")

```

The scheduled monitor automatically picks up baselining job name and waits for it before monitoring begins.

## Schedule Bias Drift Monitoring Jobs

Now that you have a baseline, you can call the `create_monitoring_schedule()` method to schedule an hourly monitor to analyze the data with a monitoring schedule. If you have submitted a baselining job, the monitor automatically picks up analysis configuration from the baselining job. If you skip the baselining step or the capture dataset has a different nature from the training dataset, you must provide the analysis configuration.

```

model_bias_analysis_config = None
if not model_bias_monitor.latest_baselining_job:
    model_bias_analysis_config = BiasAnalysisConfig(
        model_bias_config,
        headers=all_headers,
        label=label_header,
    )
model_bias_monitor.create_monitoring_schedule(
    analysis_config=model_bias_analysis_config,
    output_s3_uri=s3_report_path,
)

```

```

endpoint_input=EndpointInput(
    endpoint_name=endpoint_name,
    destination="/opt/ml/processing/input/endpoint",
    start_time_offset="-PT1H",
    end_time_offset="-PT0H",
    probability_threshold_attribute=0.8,
),
ground_truth_input=ground_truth_upload_path,
schedule_cron_expression=schedule_expression,
)
print(f"Model bias monitoring schedule: {model_bias_monitor.monitoring_schedule_name}")

```

## Inspect Reports for Data Bias Drift

If you are not able to inspect the results of the monitoring in the generated reports in SageMaker Studio, you can print them out as follows:

```

schedule_desc = model_bias_monitor.describe_schedule()
execution_summary = schedule_desc.get("LastMonitoringExecutionSummary")
if execution_summary and execution_summary["MonitoringExecutionStatus"] in ["Completed",
    "CompletedWithViolations"]:
    last_model_bias_monitor_execution = model_bias_monitor.list_executions()[-1]
    last_model_bias_monitor_execution_report_uri =
    last_model_bias_monitor_execution.output.destination
    print(f'Report URI: {last_model_bias_monitor_execution_report_uri}')
    last_model_bias_monitor_execution_report_files =
    sorted(S3Downloader.list(last_model_bias_monitor_execution_report_uri))
    print("Found Report Files:")
    print("\n ".join(last_model_bias_monitor_execution_report_files))
else:
    last_model_bias_monitor_execution = None
    print("====STOP==== \n No completed executions to inspect further. Please wait till an
execution completes or investigate previously reported failures.")

```

If there are violations compared to the baseline, they are listed here:

```

if last_model_bias_monitor_execution:
    model_bias_violations = last_model_bias_monitor_execution.constraintViolations()
    if model_bias_violations:
        print(model_bias_violations.body_dict)

```

In SageMaker Studio, you can see visualizations of the analysis results and CloudWatch metrics by choosing the **Endpoints** tab, and then double-clicking the endpoint.

## Monitor Feature Attribution Drift for Models in Production

A drift in the distribution of live data for models in production can result in a corresponding drift in the feature attribution values, just as it could cause a drift in bias when monitoring bias metrics. Amazon SageMaker Clarify feature attribution monitoring helps data scientists and ML engineers monitor predictions for feature attribution drift on a regular basis. As the model is monitored, customers can view exportable reports and graphs detailing feature attributions in SageMaker Studio and configure alerts in Amazon CloudWatch to receive notifications if it is detected that the attribution values drift beyond a certain threshold.

To illustrate this with a specific situation, consider a hypothetical scenario for college admissions. Assume that we observe the following (aggregated) feature attribution values in the training data and in the live data:

### College Admission Hypothetical Scenario

Feature	Attribution in training data	Attribution in live data
SAT score	0.70	0.10
GPA	0.50	0.20
Class rank	0.05	0.70

The change from training data to live data appears significant. The feature ranking has completely reversed. Similar to the bias drift, the feature attribution drifts might be caused by a change in the live data distribution and warrant a closer look into the model behavior on the live data. Again, the first step in these scenarios is to raise an alarm that a drift has happened.

We can detect the drift by comparing how the ranking of the individual features changed from training data to live data. In addition to being sensitive to changes in ranking order, we also want to be sensitive to the raw attribution score of the features. For instance, given two features that fall in the ranking by the same number of positions going from training to live data, we want to be more sensitive to the feature that had a higher attribution score in the training data. With these properties in mind, we use the Normalized Discounted Cumulative Gain (NDCG) score for comparing the feature attributions rankings of training and live data.

Specifically, assume we have the following:

- $F=[f_1, \dots, f_m]$  is the list of features sorted with respect to their attribution scores in the training data where  $m$  is the total number of features. For instance, in our case,  $F=[\text{SAT Score}, \text{GPA}, \text{Class Rank}]$ .
- $a(f)$  is a function that returns the feature attribution score on the training data given a feature  $f$ . For example,  $a(\text{SAT Score}) = 0.70$ .
- $F'=[f'_1, \dots, f'_m]$  is the list of features sorted with respect to their attribution scores in the live data. For example,  $F'=[\text{Class Rank}, \text{GPA}, \text{SAT Score}]$ .

Then, we can compute the NDCG as:

$$\text{NDCG}=\text{DCG}/\text{iDCG}$$

with

- $\text{DCG} = \sum_1^m a(f'_i)/\log_2(i+1)$
- $\text{iDCG} = \sum_1^m a(f_i)/\log_2(i+1)$

The quantity DCG measures whether features with high attribution in the training data are also ranked higher in the feature attribution computed on the live data. The quantity iDCG measures the *ideal score* and it's just a normalizing factor to ensure that the final quantity resides in the range  $[0, 1]$ , with 1 being the best possible value. A NDCG value of 1 means that the feature attribution ranking in the live data is the same as the one in the training data. In this particular example, because the ranking changed by quite a bit, the NDCG value is 0.69.

In SageMaker Clarify, if the NDCG value is below 0.90, we automatically raise an alert.

## Model Monitor Example Notebook

SageMaker Clarify provides the following example notebook that shows how to capture real-time inference data, create a baseline to monitor evolving bias against, and inspect the results:

- [Monitoring bias drift and feature attribution drift Amazon SageMaker Clarify](#) – Use Amazon SageMaker Model Monitor to monitor bias drift and feature attribution drift over time.

This notebook has been verified to run in SageMaker Studio only. If you need instructions on how to open a notebook in SageMaker Studio, see [Create or Open an Amazon SageMaker Studio Notebook \(p. 79\)](#). If you're prompted to choose a kernel, choose **Python 3 (Data Science)**. The following topics contain the highlights from the last two steps, and they contain code examples from the example notebook.

### Topics

- [Create a SHAP Baseline for Models in Production \(p. 1975\)](#)
- [Schedule Feature Attribute Drift Monitoring Jobs \(p. 1976\)](#)
- [Inspect Reports for Feature Attribute Drift in Production Models \(p. 1976\)](#)

## Create a SHAP Baseline for Models in Production

Explanations are typically contrastive, that is, they account for deviations from a baseline. For information on explainability baselines, see [SHAP Baselines for Explainability \(p. 1854\)](#).

In addition to providing explanations for per-instance inferences, SageMaker Clarify also supports global explanation for ML models that helps you understand the behavior of a model as a whole in terms of its features. SageMaker Clarify generates a global explanation of an ML model by aggregating the Shapley values over multiple instances. SageMaker Clarify supports the following different ways of aggregation, which you can use to define baselines:

- `mean_abs` – Mean of absolute SHAP values for all instances.
- `median` – Median of SHAP values for all instances.
- `mean_sq` – Mean of squared SHAP values for all instances.

After you have configured your application to capture real-time inference data, the first task to monitor for drift in feature attribution is to create a baseline to compare against. This involves configuring the data inputs, which groups are sensitive, how the predictions are captured, and the model and its posttraining bias metrics. Then you need to start the baselining job. Model explainability monitor can explain the predictions of a deployed model that's producing inferences and detect feature attribution drift on a regular basis.

```
model_explainability_monitor = ModelExplainabilityMonitor(  
    role=role,  
    sagemaker_session=sagemaker_session,  
    max_runtime_in_seconds=1800,  
)
```

In this example, the explainability baselining job shares the test dataset with the bias baselining job, so it uses the same `DataConfig`, and the only difference is the job output URI.

```
model_explainability_baselining_job_result_uri = f"{baseline_results_uri}/  
model_explainability"  
model_explainability_data_config = DataConfig(  
    s3_data_input_path=validation_dataset,  
    s3_output_path=model_explainability_baselining_job_result_uri,  
    label=label_header,  
    headers=all_headers,  
    dataset_type=dataset_type,  
)
```

Currently the SageMaker Clarify explainer offers a scalable and efficient implementation of SHAP, so the explainability config is `SHAPConfig`, including the following:

- **baseline** – A list of rows (at least one) or S3 object URI to be used as the baseline dataset in the Kernel SHAP algorithm. The format should be the same as the dataset format. Each row should contain only the feature columns/values and omit the label column/values.
- **num\_samples** – Number of samples to be used in the Kernel SHAP algorithm. This number determines the size of the generated synthetic dataset to compute the SHAP values.
- **agg\_method** – Aggregation method for global SHAP values. Following are valid values:
  - **mean\_abs** – Mean of absolute SHAP values for all instances.
  - **median** – Median of SHAP values for all instances.
  - **mean\_sq** – Mean of squared SHAP values for all instances.
- **use\_logit** – Indicator of whether the logit function is to be applied to the model predictions. Default is `False`. If `use_logit` is `True`, the SHAP values will have log-odds units.
- **save\_local\_shap\_values (bool)** – Indicator of whether to save the local SHAP values in the output location. Default is `True`.

```
# Here use the mean value of test dataset as SHAP baseline
test_dataframe = pd.read_csv(test_dataset, header=None)
shap_baseline = [list(test_dataframe.mean())]

shap_config = SHAPConfig(
    baseline=shap_baseline,
    num_samples=100,
    agg_method="mean_abs",
    save_local_shap_values=False,
)
```

Start a baselining job. The same `model_config` is required because the explainability baselining job needs to create a shadow endpoint to get predictions for the generated synthetic dataset.

```
model_explainability_monitor.suggest_baseline(
    data_config=model_explainability_data_config,
    model_config=model_config,
    explainability_config=shap_config,
)
print(f"ModelExplainabilityMonitor baselining job:
{model_explainability_monitor.latest_baselining_job_name}")
```

## Schedule Feature Attribute Drift Monitoring Jobs

Model explainability monitoring helps you understand and interpret the predictions made by your ML models. When Model Monitor is configured to monitor model explainability, SageMaker automatically detects any drift in relative importance of features and creates reports explaining feature attributions.

Call the `create_monitoring_schedule()` method to schedule an hourly monitor to analyze the data with a monitoring schedule. If a baselining job has been submitted, the monitor automatically picks up analysis configuration from the baselining job. However, if you skip the baselining step or the capture dataset has a different nature from the training dataset, you have to provide the analysis configuration. `ModelConfig` is required by `ExplainabilityAnalysisConfig` for the same reason that it's required for the baselining job. Note that only features are required for computing feature attribution, so you should exclude ground truth labeling.

## Inspect Reports for Feature Attribute Drift in Production Models

After the schedule that you set up is started by default, you need to wait for its first execution to start, and then stop the schedule to avoid incurring charges.

To inspect the reports, use the following code:

```

schedule_desc = model_explainability_monitor.describe_schedule()
execution_summary = schedule_desc.get("LastMonitoringExecutionSummary")
if execution_summary and execution_summary["MonitoringExecutionStatus"] in ["Completed",
    "CompletedWithViolations"]:
    last_model_explainability_monitor_execution =
        model_explainability_monitor.list_executions()[-1]
    last_model_explainability_monitor_execution_report_uri =
        last_model_explainability_monitor_execution.output.destination
    print(f'Report URI: {last_model_explainability_monitor_execution_report_uri}')
    last_model_explainability_monitor_execution_report_files =
        sorted(S3Downloader.list(last_model_explainability_monitor_execution_report_uri))
    print("Found Report Files:")
    print("\n ".join(last_model_explainability_monitor_execution_report_files))
else:
    last_model_explainability_monitor_execution = None
    print("====STOP==== \n No completed executions to inspect further. Please wait till an
execution completes or investigate previously reported failures.")

```

If there are any violations compared to the baseline, they are listed here:

```

if last_model_explainability_monitor_execution:
    model_explainability_violations =
        last_model_explainability_monitor_execution.constraintViolations()
    if model_explainability_violations:
        print(model_explainability_violations.body_dict)

```

In SageMaker Studio, you can see visualizations of the analysis results and CloudWatch metrics by choosing the **Endpoints** tab, and then double-clicking the endpoint.

## Capture Data

To use Model Monitor, configure your real-time inference endpoint to capture data from requests and responses and store the captured data in Amazon S3. Model monitor compares metrics from this data with a baseline that you create for the model. For information about creating a baseline, see [Create a Baseline \(p. 1959\)](#).

### Note

To prevent impact to inference requests, Data Capture stops capturing requests at high levels of disk usage. It is recommended you keep your disk utilization below 75% in order to ensure data capture continues capturing requests.

### To set up data capture

1. First, configure the Amazon S3 buckets Model Monitor uses to store the captured data.

```

import boto3
import re
import json
from sagemaker import get_execution_role, session

region= boto3.Session().region_name

role = get_execution_role()
print("RoleArn: {}".format(role))

# You can use a different bucket, but make sure the role you chose for this notebook
# has s3:PutObject permissions. This is the bucket into which the data is captured
bucket = session.Session(boto3.Session()).default_bucket()
print("Demo Bucket: {}".format(bucket))
prefix = 'sagemaker/DEMO-ModelMonitor'

```

```

data_capture_prefix = '{}/datacapture'.format(prefix)
s3_capture_upload_path = 's3://{}{}'.format(bucket, data_capture_prefix)
reports_prefix = '{}/reports'.format(prefix)
s3_report_path = 's3://{}{}'.format(bucket, reports_prefix)
code_prefix = '{}/code'.format(prefix)
s3_code_preprocessor_uri = 's3://{}{}'.format(bucket, code_prefix,
    'preprocessor.py')
s3_code_postprocessor_uri = 's3://{}{}'.format(bucket, code_prefix,
    'postprocessor.py')

print("Capture path: {}".format(s3_capture_upload_path))
print("Report path: {}".format(s3_report_path))
print("Preproc Code path: {}".format(s3_code_preprocessor_uri))
print("Postproc Code path: {}".format(s3_code_postprocessor_uri))

```

2. Next, upload the pre-trained model to Amazon S3.

```

model_file = open("model/your-prediction-model.tar.gz", 'rb')
s3_key = os.path.join(prefix, 'your-prediction-model.tar.gz')
boto3.Session().resource('s3').Bucket(bucket).Object(s3_key).upload_fileobj(model_file)

```

3. Configure the data you want to capture by configuring the data you want to capture in a [DataCaptureConfig](#) structure. You can capture the request payload, the response payload, or both with this configuration.

```

from sagemaker.model_monitor import DataCaptureConfig

endpoint_name = 'your-pred-model-monitor-' + strftime("%Y-%m-%d-%H-%M-%S", gmtime())
print("EndpointName={}".format(endpoint_name))

data_capture_config=DataCaptureConfig(
    enable_capture = True,
    sampling_percentage=100,
    destination_s3_uri=s3_capture_upload_path)

```

4. Enable data capture by passing the configuration you created in the previous step when you deploy the model.

```

predictor = model.deploy(initial_instance_count=1,
    instance_type='ml.m4.xlarge',
    endpoint_name=endpoint_name
    data_capture_config=data_capture_config)

```

5. Invoke the endpoint to send data to the endpoint to get inferences in real time. Because you enabled the data capture in the previous steps, the request and response payload, along with some additional metadata, is saved in the Amazon S3 location that you specified in [DataCaptureConfig](#).

```

from sagemaker.predictor import RealTimePredictor
import time

predictor = RealTimePredictor(endpoint=endpoint_name,content_type='text/csv')

# get a subset of test data for a quick test
!head -120 test_data/test-dataset-input-cols.csv > test_data/test_sample.csv
print("Sending test traffic to the endpoint {}. \nPlease
wait...".format(endpoint_name))

with open('test_data/test_sample.csv', 'r') as f:
    for row in f:
        payload = row.rstrip('\n')
        response = predictor.predict(data=payload)

```

```

    time.sleep(0.5)
    print("Done!")

```

6. View captured data by listing the data capture files stored in Amazon S3. Expect to see different files from different time periods, organized based on the hour when the invocation occurred.

```

s3_client = boto3.Session().client('s3')
current_endpoint_capture_prefix = '{} / {}'.format(data_capture_prefix, endpoint_name)
result = s3_client.list_objects(Bucket=bucket, Prefix=current_endpoint_capture_prefix)
capture_files = [capture_file.get("Key") for capture_file in result.get('Contents')]
print("Found Capture Files:")
print("\n ".join(capture_files))

```

The format of the Amazon S3 path is as follows:

```

s3://{{destination-bucket-prefix}}/{{endpoint-name}}/{{variant-name}}/yyyy/mm/dd/hh/
filename.jsonl

```

## Schedule Monitoring Jobs

Amazon SageMaker Model Monitor provides you the ability to continuously monitor the data collected from the endpoints on a schedule. You can create a monitoring schedule with the [CreateMonitoringSchedule](#) API with a predefined periodic interval. For example, every x hours (x can range from 1 to 23).

With a monitoring schedule, SageMaker can kick off processing jobs at a specified frequency to analyze the data collected during a given period. SageMaker provides a prebuilt container for performing analysis on tabular datasets. In the processing job, SageMaker compares the dataset for the current analysis with the baseline statistics, constraints provided and generate a violations report. In addition, CloudWatch metrics are emitted for each feature under analysis. Alternatively, you could choose to bring your own container as outlined in the [Bring Your Own Containers \(p. 1993\)](#) topic.

You can create a model monitoring schedule for the endpoint created earlier. Use the baseline resources (constraints and statistics) to compare against the real-time traffic. For this example, upload the training dataset that was used to train the pretrained model included in this example. If you already have it in Amazon S3, you can point to it directly.

```

# copy over the training dataset to Amazon S3 (if you already have it in Amazon S3, you
# could reuse it)
baseline_prefix = prefix + '/baselining'
baseline_data_prefix = baseline_prefix + '/data'
baseline_results_prefix = baseline_prefix + '/results'

baseline_data_uri = 's3://{{}}/{{}}'.format(bucket,baseline_data_prefix)
baseline_results_uri = 's3://{{}}/{{}}'.format(bucket, baseline_results_prefix)
print('Baseline data uri: {}'.format(baseline_data_uri))
print('Baseline results uri: {}'.format(baseline_results_uri))

```

```

training_data_file = open("test_data/training-dataset-with-header.csv", 'rb')
s3_key = os.path.join(baseline_prefix, 'data', 'training-dataset-with-header.csv')
boto3.Session().resource('s3').Bucket(bucket).Object(s3_key).upload_fileobj(training_data_file)

```

Create a model monitoring schedule for the endpoint using the baseline constraints and statistics to compare against real-time traffic.

```

from sagemaker.model_monitor import CronExpressionGenerator

```

```
from time import gmtime, strftime

mon_schedule_name = 'DEMO-xgb-churn-pred-model-monitor-schedule-' + strftime("%Y-%m-%d-%H-%M-%S", gmtime())
my_default_monitor.create_monitoring_schedule(
    schedule_name=mon_schedule_name,
    endpoint_input=predictor.endpoint,
    post_analytics_processor_script=s3_code_postprocessor_uri,
    output_s3_uri=s3_report_path,
    statistics=my_default_monitor.baseline_statistics(),
    constraints=my_default_monitor.suggested_constraints(),
    schedule_cron_expression=CronExpressionGenerator.hourly(),
    enable_cloudwatch_metrics=True,
)
```

Describe and inspect the schedule: After you describe it, observe that the `MonitoringScheduleStatus` in [MonitoringScheduleSummary](#) returned by the [ListMonitoringSchedules](#) API changes to `Scheduled`.

```
desc_schedule_result = my_default_monitor.describe_schedule()
print('Schedule status: {}'.format(desc_schedule_result['MonitoringScheduleStatus']))
```

## The cron Expression for Monitoring Schedule

To provide details for the monitoring schedule, use `ScheduleConfig`, which is a cron expression that describes details about the monitoring schedule.

Amazon SageMaker Model Monitor supports the following cron expressions:

- To set the job to start every hour, use the following:  
`Hourly: cron(0 * ? * * *)`
- To run the job daily, use the following:  
`cron(0 [00-23] ? * * *)`

For example, the following are valid cron expressions:

- Daily at 12 PM UTC: `cron(0 12 ? * * *)`
- Daily at 12 AM UTC: `cron(0 0 ? * * *)`

To support running every 6, 12 hours, Model Monitor supports the following expression:

```
cron(0 [00-23]/[01-24] ? * * *)
```

For example, the following are valid cron expressions:

- Every 12 hours, starting at 5 PM UTC: `cron(0 17/12 ? * * *)`
- Every two hours, starting at 12 AM UTC: `cron(0 0/2 ? * * *)`

### Notes

- Although the cron expression is set to start at 5 PM UTC, note that there could be a delay of 0-20 minutes from the actual requested time to run the execution.
- If you want to run on a daily schedule, don't provide this parameter. SageMaker picks a time to run every day.

- Currently, SageMaker only supports hourly integer rates between 1 hour and 24 hours.

## Amazon SageMaker Model Monitor Prebuilt Container

SageMaker provides a built-in container `sagemaker-model-monitor-analyzer` that provides you with a range of model monitoring capabilities, including constraint suggestion, statistics generation, constraint validation against a baseline, and emitting Amazon CloudWatch metrics. This container is based on Spark and is built with [Deequ](#). The prebuilt container for SageMaker Model Monitor can be accessed as follows:

`<ACCOUNT_ID>.dkr.ecr.<REGION_NAME>.amazonaws.com/sagemaker-model-monitor-analyzer`

For example: `159807026194.dkr.ecr.us-west-2.amazonaws.com/sagemaker-model-monitor-analyzer`

If you are in an Amazon region in China, the prebuilt container for SageMaker Model Monitor can be accessed as follows:

`<ACCOUNT_ID>.dkr.ecr.<REGION_NAME>.amazonaws.com.cn/sagemaker-model-monitor-analyzer`

The following table lists the supported values for account IDs and corresponding Amazon Region names.

ACCOUNT_ID	REGION_NAME
156813124566	us-east-1
777275614652	us-east-2
890145073186	us-west-1
159807026194	us-west-2
875698925577	af-south-1
001633400207	ap-east-1
574779866223	ap-northeast-1
709848358524	ap-northeast-2
126357580389	ap-south-1
245545462676	ap-southeast-1
563025443158	ap-southeast-2
536280801234	ca-central-1
453000072557	cn-north-1
453252182341	cn-northwest-1
048819808253	eu-central-1
895015795356	eu-north-1
933208885752	eu-south-1

ACCOUNT_ID	REGION_NAME
468650794304	eu-west-1
749857270468	eu-west-2
680080141114	eu-west-3
607024016150	me-south-1
539772159869	sa-east-1
362178532790	us-gov-west-1

To write your own analysis container, see the container contract described in [Customize Monitoring \(p. 1990\)](#).

## Interpret Results

After you run a baseline processing job and obtained statistics and constraint for your dataset, you can execute monitoring jobs that calculate statistics and list any violations encountered relative to the baseline constraints. Amazon CloudWatch metrics are also reported in your account by default. For information on viewing the results of monitoring in Amazon SageMaker Studio, see [Visualize Results in Amazon SageMaker Studio \(p. 1984\)](#).

### List Executions

The schedule starts monitoring jobs at the specified intervals. The following code lists the latest five executions. If you are running this code after creating the hourly schedule, the executions might be empty, and you might have to wait until you cross the hour boundary (in UTC) to see the executions start. The following code includes the logic for waiting.

```
mon_executions = my_default_monitor.list_executions()
print("We created a hourly schedule above and it will kick off executions ON the hour (plus
0 - 20 min buffer.\nWe will have to wait till we hit the hour...")

while len(mon_executions) == 0:
    print("Waiting for the 1st execution to happen...")
    time.sleep(60)
    mon_executions = my_default_monitor.list_executions()
```

### Inspect a Specific Execution

In the previous step, you picked up the latest completed or failed scheduled execution. You can explore what went right or wrong. The terminal states are:

- **Completed** – The monitoring execution completed and no issues were found in the violations report.
- **CompletedWithViolations** – The execution completed, but constraint violations were detected.
- **Failed** – The monitoring execution failed, possibly due to client error (for example, a role issues) or infrastructure issues. To identify the cause, see the `FailureReason` and `ExitMessage`.

```
latest_execution = mon_executions[-1] # latest execution's index is -1, previous is -2 and
so on..
time.sleep(60)
latest_execution.wait(logs=False)
```

```

print("Latest execution status: {}".format(latest_execution.describe()
['ProcessingJobStatus']))
print("Latest execution result: {}".format(latest_execution.describe()['ExitMessage']))

latest_job = latest_execution.describe()
if (latest_job['ProcessingJobStatus'] != 'Completed'):
    print("====STOP==== \n No completed executions to inspect further. Please wait till
an execution completes or investigate previously reported failures.")

```

```

report_uri=latest_execution.output.destination
print('Report Uri: {}'.format(report_uri))

```

## List Generated Reports

List the generated reportsUse the following code to list the generated reports.

```

from urllib.parse import urlparse
s3uri = urlparse(report_uri)
report_bucket = s3uri.netloc
report_key = s3uri.path.lstrip('/')
print('Report bucket: {}'.format(report_bucket))
print('Report key: {}'.format(report_key))

s3_client = boto3.Session().client('s3')
result = s3_client.list_objects(Bucket=report_bucket, Prefix=report_key)
report_files = [report_file.get("Key") for report_file in result.get('Contents')]
print("Found Report Files:")
print("\n ".join(report_files))

```

## Violations Report

If there are violations compared to the baseline, they are generated in the violations report. Use the following code to list the violations.

```

violations = my_default_monitor.latest_monitoring_constraint_violations()
pd.set_option('display.max_colwidth', -1)
constraints_df = pd.io.json.json_normalize(violations.body_dict["violations"])
constraints_df.head(10)

```

This applies only to datasets that contain tabular data. The following schema files specify the statistics calculated and the violations monitored for.

### Output Files for Tabular Datasets

File Name	Description
<b>statistics.json</b>	Contains columnar statistics for each feature in the dataset that is analyzed. See the schema of this file in the next topic.  <b>Note</b> This file is created only for data quality monitoring.
<b>constraintsViolations.json</b>	Contains a list of violations found in this current set of data as compared to the baseline statistics and constraints file

File Name	Description
	specified in the <code>baseline_constraints</code> and <code>baseline_statistics</code> paths.

The [Amazon SageMaker Model Monitor Prebuilt Container \(p. 1981\)](#) saves a set of Amazon CloudWatch metrics for each feature by default.

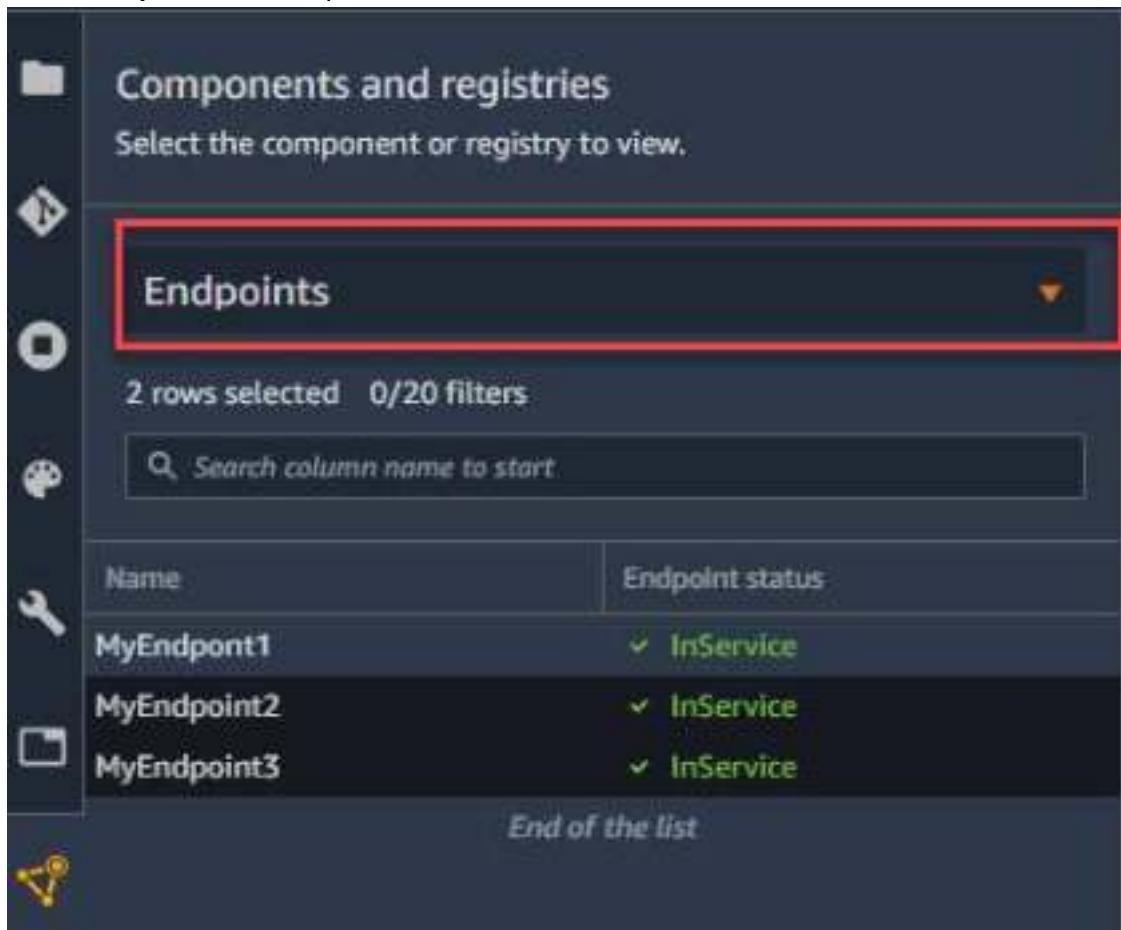

The container code can emit CloudWatch metrics in this location: `/opt/ml/output/metrics/cloudwatch`.

## Visualize Results in Amazon SageMaker Studio

You can also visualize the results of monitoring in Amazon SageMaker Studio. You can view the details of any monitoring job run, and you can create charts that show the baseline and captured values for any metric that the monitoring job calculates.

### To view the detailed results of a monitoring job

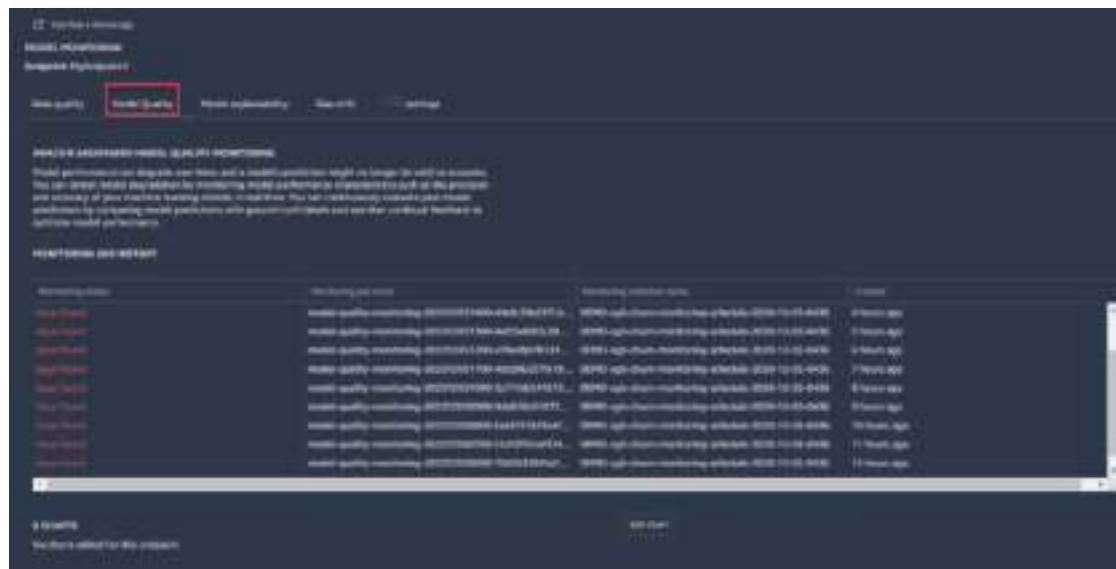

1. Sign in to Studio. For more information, see [Onboard to Amazon SageMaker Studio \(p. 35\)](#).
2. In the left navigation pane, choose the **Components and registries** icon (- 3. Choose **Endpoints** in the drop-down menu.

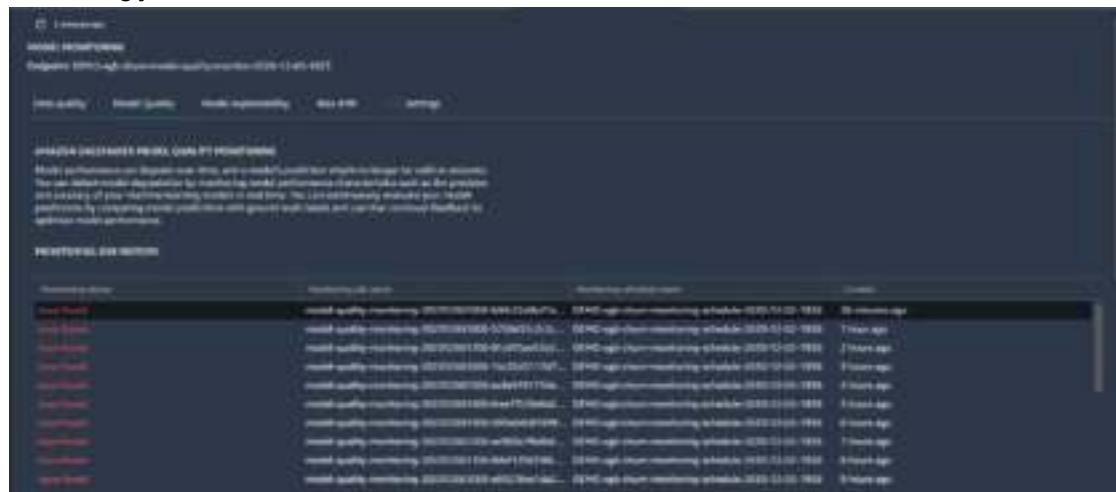

The screenshot shows the 'Components and registries' page in Amazon SageMaker Studio. On the left, there is a vertical sidebar with icons for different components: a folder for 'Components and registries', a diamond for 'Data Wrangler', a square for 'ML Projects', a paint palette for 'Notebooks', a wrench for 'Endpoints', a folder for 'Transforms', and a key for 'Monitoring'. The main area has a dark background with light-colored text. At the top, it says 'Components and registries' and 'Select the component or registry to view.' Below that, a dropdown menu is open, with the option 'Endpoints' highlighted by a red rectangle. Underneath the dropdown, it says '2 rows selected 0/20 filters' and there is a search bar with the placeholder 'Search column name to start'. A table follows, with columns 'Name' and 'Endpoint status'. It contains three rows: 'MyEndpoint1' with 'InService', 'MyEndpoint2' with 'InService', and 'MyEndpoint3' with 'InService'. At the bottom of the table, it says 'End of the list'. The entire interface is framed by a thick red border.

Name	Endpoint status
MyEndpoint1	✓ InService
MyEndpoint2	✓ InService
MyEndpoint3	✓ InService

4. On the endpoint tab, choose the monitoring type for which you want to see job details.

- Choose the name of the monitoring job run for which you want to view details from the list of monitoring jobs.

6. The **MONITORING JOB DETAILS** tab opens with a detailed report of the monitoring job.

**MONITORING JOB DETAILS**

Monitoring Execution Name: model-quality-monitoring-202012061900-h0455d6a21a4e972867608

Processing Job ARN: arn:aws:sagemaker-us-east-2:123456789012:processing-job/model-quality-monitoring-202012061900-h0455d6a21a4e972867608

Monitoring Schedule: DEMO-rgb-churn-monitoring-schedule-2020-12-02-1958

Monitoring Job Status: Completed With Violations

**MONITORING JOB REPORT**

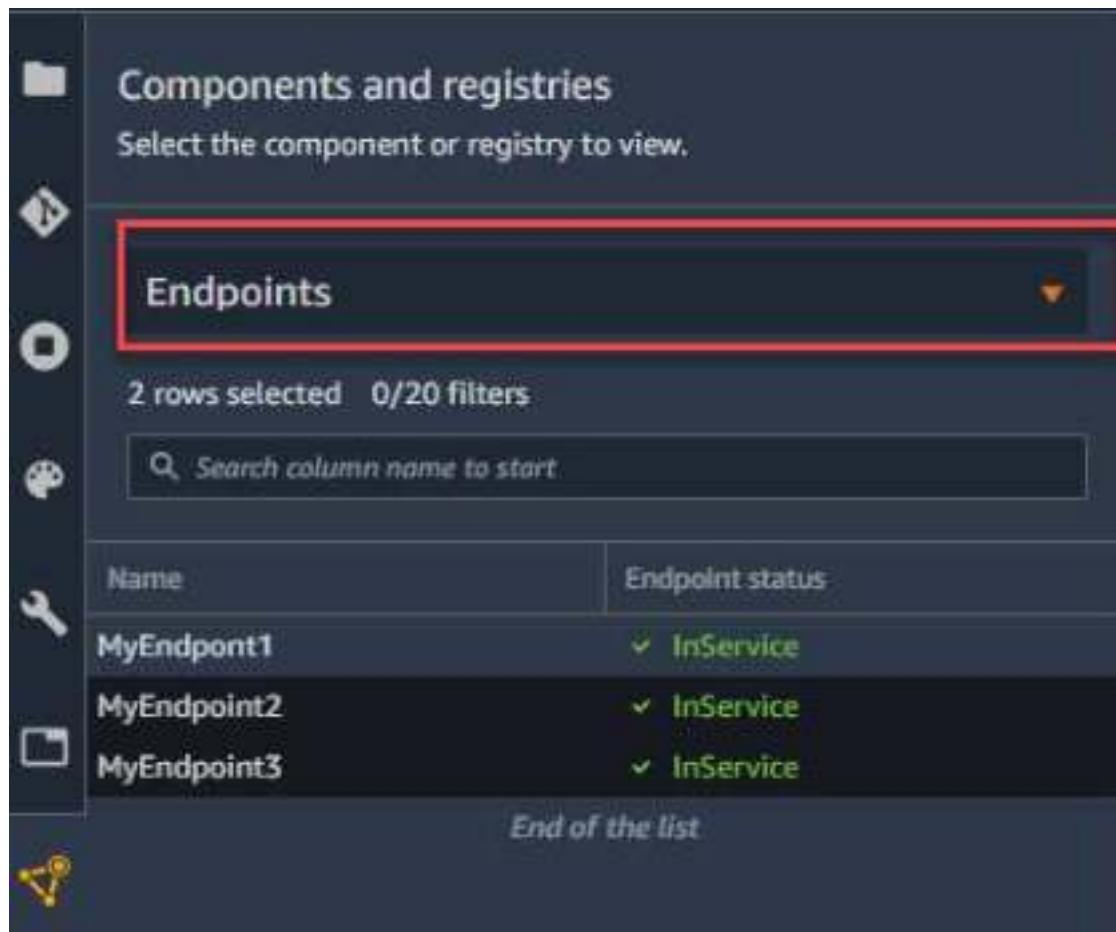

Amazon SageMaker Model Monitor compared this run against the baseline and detected these constraint violations.

Constraint	Violation details
LessThanThreshold	Metric precision with 0.7684444444444445 +/- 0.00601752812981426 was LessThanThreshold '1.0'
LessThanThreshold	Metric truePositiveRate with 0.0648480373105345 +/- 0.00163285764989067 was LessThanThreshold '0.5714285714285714'
LessThanThreshold	Metric f1 with 0.12294456958620442 +/- 0.0027741665172884867 was LessThanThreshold '0.7272727272727273'
LessThanThreshold	Metric accuracy with 0.30909876265466815 +/- 0.0011167989498387929 was LessThanThreshold '0.9402985074636860'
Greater Than Threshold	Metric falsePositiveRate with 0.05395658189216684 +/- 0.0018372499707814655 was GreaterThanThreshold '0.0'
LessThanThreshold	Metric trueNegativeRate with 0.9460854189079331 +/- 0.0018372499707814401 was LessThanThreshold '1.0'
Greater Than Threshold	Metric falseNegativeRate with 0.3331519626894679 +/- 0.001632857649890645 was GreaterThanThreshold '0.4285714285714286'
LessThanThreshold	Metric recall with 0.0668480373105345 +/- 0.00163285764989067 was LessThanThreshold '0.5714285714285714'
LessThanThreshold	Metric f2 with 0.08177239854615355 +/- 0.0019556109564544965 was LessThanThreshold '0.623'

You can create a chart that displays the baseline and captured metrics for a time period.

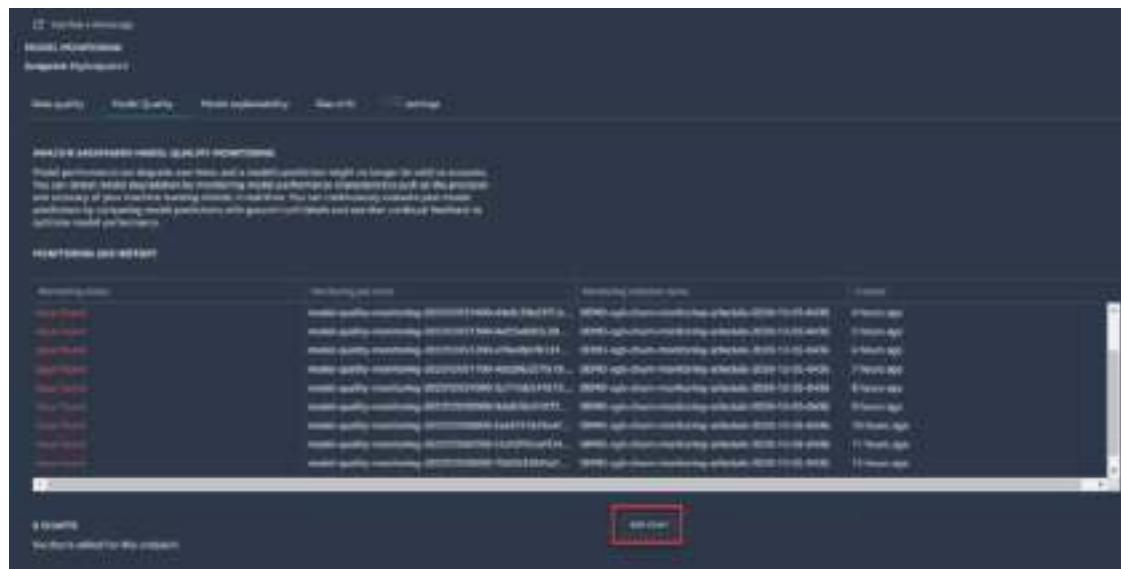

### To create a chart in SageMaker Studio to visualize monitoring results

1. Sign in to Studio. For more information, see [Onboard to Amazon SageMaker Studio \(p. 35\)](#).
2. In the left navigation pane, choose the **Components and registries** icon (  ).
3. Choose **Endpoints** in the drop-down menu.

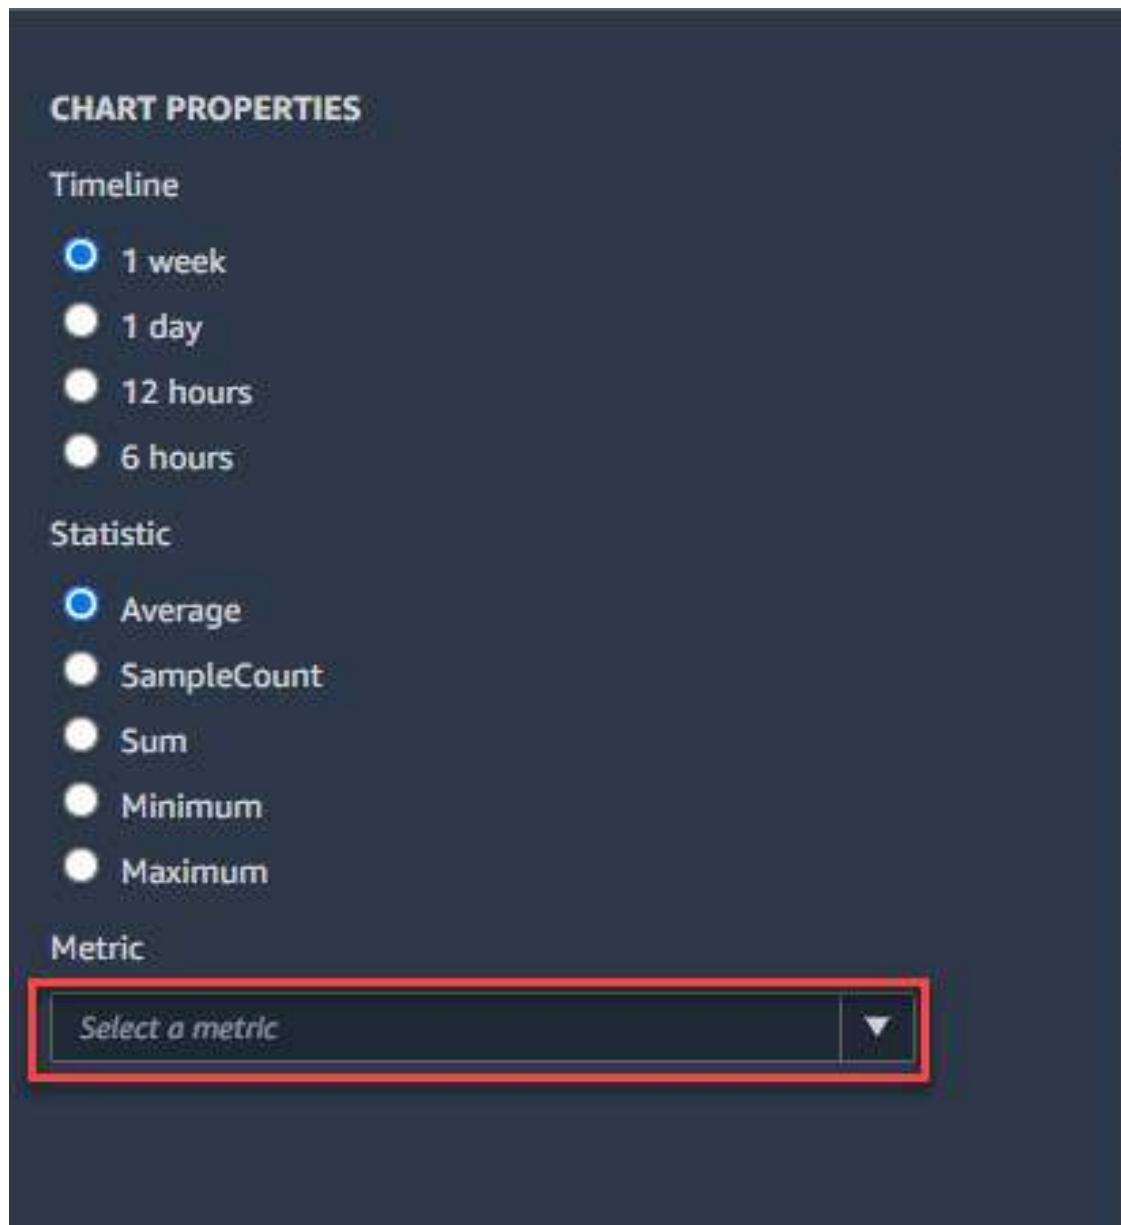

- On the **Endpoint** tab, choose the monitoring type you want to create a chart for. This example shows a chart for the **Model quality** monitoring type.

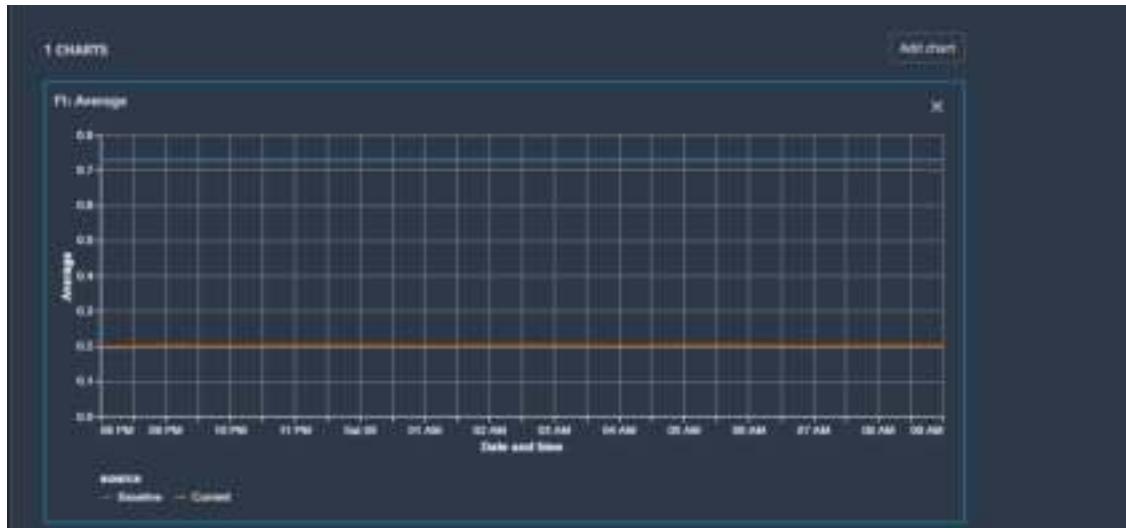

- ## 5. Choose Add chart.

6. On the **CHART PROPERTIES** tab, choose the time period, statistic, and metric that you want to chart. This example shows a chart for a **Timeline of 1 week**, the **Average Statistic** of, and the **F1 Metric**.

7. The chart that shows the baseline and current metric statistic you chose in the previous step shows up in the **Endpoint** tab.

## Advanced Topics

The following sections contain more advanced tasks that explain how to customize monitoring using preprocessing and postprocessing scripts, how to build your own container, and how to use Amazon CloudFormation to create a monitoring schedule.

### Topics

- [Customize Monitoring \(p. 1990\)](#)
- [Create a Monitoring Schedule with an Amazon CloudFormation Custom Resource \(p. 2000\)](#)

## Customize Monitoring

In addition to using the built-in monitoring mechanisms, you can create your own custom monitoring schedules and procedures using preprocessing and postprocessing scripts or by using or building your own container.

### Topics

- [Preprocessing and Postprocessing \(p. 1990\)](#)
- [Bring Your Own Containers \(p. 1993\)](#)

## Preprocessing and Postprocessing

In addition to using the built-in mechanisms, you can extend the code with the preprocessing and postprocessing scripts.

### Topics

- [Postprocessing Script \(p. 1990\)](#)
- [Preprocessing Script \(p. 1991\)](#)

## Postprocessing Script

You can extend the code with the postprocessing script by following this contract:

```
def postprocess_handler():
    print("Hello from post-proc script!")
```

Specify it as a path in Amazon Simple Storage Service (Amazon S3) in the CreateMonitoringSchedule request, as shown following:

```
.MonitoringAppSpecification.PostAnalyticsProcessorSourceUri.
```

### Preprocessing Script

The Amazon SageMaker Model Monitor container works only with tabular or flattened JSON structures. We provide a per-record preprocessor for some small changes required to transform the dataset. For example, if your output is an array [1.0, 2.1], you need to convert this into a flattened JSON, like {"prediction0": 1.0, "prediction1" : 2.1"}. A sample implementation might look like the following:

```
def preprocess_handler(inference_record):

    input_data = inference_record.endpoint_input.data
    output_data = inference_record.endpoint_output.data

    input_data['feature0'] = random.randint(1, 3)
    input_data['feature1'] = random.uniform(0, 1.6)
    input_data['feature2'] = random.uniform(0, 1.6)

    output_data['prediction0'] = random.uniform(1, 30)

    return {**input_data, **output_data}
```

Specify it as a path in Amazon S3 in the CreateMonitoringSchedule request:

```
.MonitoringAppSpecification.RecordPreprocessorSourceUri.
```

The structure of the inference\_record is defined as follows:

```
KEY_EVENT_METADATA = "eventMetadata"
KEY_EVENT_METADATA_EVENT_ID = "eventId"
KEY_EVENT_METADATA_EVENT_TIME = "inferenceTime"
KEY_EVENT_METADATA_CUSTOM_ATTR = "customAttributes"

KEY_EVENTDATA = "captureData"
KEY_EVENTDATA_INPUT = "endpointInput"
KEY_EVENTDATA_OUTPUT = "endpointOutput"
KEY_EVENTDATA_ENCODING = "encoding"
KEY_EVENTDATA_DATA = "data"
KEY_EVENTDATA_OBSERVED_CONTENT_TYPE = "observedContentType"
KEY_EVENTDATA_MODE = "mode"

KEY_EVENT_VERSION = "eventVersion"

"""
{
    "captureData": {
        "endpointInput": {
            "observedContentType": "text/csv",
            "mode": "INPUT",
            "data": "132,25,113.2,96,269.9,107,,0,0,0,0,0,0,1,0,1,0,0,1",
            "encoding": "CSV"
        },
        "endpointOutput": {
            "observedContentType": "text/csv; charset=utf-8",
```

```

        "mode": "OUTPUT",
        "data": "0.01076381653547287",
        "encoding": "CSV"
    }
},
"eventMetadata": {
    "eventId": "fecalab1-8025-47e3-8f6a-99e3fdd7b8d9",
    "inferenceTime": "2019-11-20T23:33:12Z"
},
"eventVersion": "0"
}
"""

        self.event_dict[KEY_EVENTDATA][
            KEY_EVENTDATA_OUTPUT
        ] = self.endpoint_output.as_dict()
self._event_dict_postprocessed = True
return self.event_dict
```

## Bring Your Own Containers

Amazon SageMaker Model Monitor provides a prebuilt container with ability to analyze the data captured from endpoints for tabular datasets. If you would like to bring your own container, Model Monitor provides extension points which you can leverage.

Under the hood, when you create a `MonitoringSchedule`, Model Monitor ultimately kicks off processing jobs. Hence the container needs to be aware of the processing job contract documented in the [Build Your Own Processing Container \(Advanced Scenario\) \(p. 668\)](#) topic. Note that Model Monitor kicks off the processing job on your behalf per the schedule. While invoking, Model Monitor sets up additional environment variables for you so that your container has enough context to process the data for that particular execution of the scheduled monitoring. For additional information on container inputs, see the [Container Contract Inputs \(p. 1993\)](#).

In the container, using the above environment variables/context, you can now analyze the dataset for the current period in your custom code. After this analysis is complete, you can chose to emit your reports to be uploaded to an S3 bucket. The reports that the prebuilt container generates are documented in [Container Contract Outputs \(p. 1995\)](#). If you would like the visualization of the reports to work in SageMaker Studio, you should follow the same format. You can also choose to emit completely custom reports.

You also emit CloudWatch metrics from the container by following the instructions in [CloudWatch Metrics for Bring Your Own Containers \(p. 1999\)](#).

### Topics

- [Container Contract Inputs \(p. 1993\)](#)
- [Container Contract Outputs \(p. 1995\)](#)
- [CloudWatch Metrics for Bring Your Own Containers \(p. 1999\)](#)

### Container Contract Inputs

The Amazon SageMaker Model Monitor platform invokes your container code according to a specified schedule. If you chose to write your own container code, the following environment variables are available for your container code. In this context, you can analyze the current dataset or evaluate the constraints if you chose to and emit metrics, if applicable.

```
"Environment": {
    "dataset_format": "{\"sagemakerCaptureJson\": {\"captureIndexNames\": [\"endpointInput\",
\"endpointOutput\"]}}",
    "dataset_source": "/opt/ml/processing/endpointdata",
    "end_time": "2019-12-01T16: 20: 00Z",
    "output_path": "/opt/ml/processing/resultdata",
    "publish_cloudwatch_metrics": "Disabled",
    "sagemaker_endpoint_name": "endpoint-name",
    "sagemaker_monitoring_schedule_name": "schedule-name",
    "start_time": "2019-12-01T15: 20: 00Z"
```

}

## Parameters

Parameter Name	Description
<code>dataset_format</code>	For a job started from a <code>MonitoringSchedule</code> backed by an <code>Endpoint</code> , this is <code>sageMakerCaptureJson</code> with the capture indices <code>endpointInput</code> , or <code>endpointOutput</code> , or both.
<code>dataset_source</code>	The local path in which the data corresponding to the monitoring period, as specified by <code>start_time</code> and <code>end_time</code> , are available. At this path, the data is available in <code>/{endpoint-name}/{variant-name}/yyyy/mm/dd/hh</code> .  We sometimes download more than what is specified by the start and end times. It is up to the container code to parse the data as required.
<code>output_path</code>	The local path to write output reports and other files. You specify this parameter in the <code>CreateMonitoringSchedule</code> request as <code>MonitoringOutputConfig.MonitoringOutput[0].LocalPath</code> . It is uploaded to the S3Uri path specified in <code>MonitoringOutputConfig.MonitoringOutput[0].S3Uri</code> .
<code>publish_cloudwatch_metrics</code>	For a job launched by <code>CreateMonitoringSchedule</code> , this parameter is set to <code>Enabled</code> . The container can choose to write the Amazon CloudWatch output file at <code>[filepath]</code> .
<code>sagemaker_endpoint_name</code>	The name of the <code>Endpoint</code> that this scheduled job was launched for.
<code>sagemaker_monitoring_schedule_name</code>	The name of the <code>MonitoringSchedule</code> that launched this job.
<code>*sagemaker_endpoint_datacapture_prefix*</code>	The prefix specified in the <code>DataCaptureConfig</code> parameter of the <code>Endpoint</code> . The container can use this if it needs to directly access more data than already downloaded by SageMaker at the <code>dataset_source</code> path.
<code>start_time, end_time</code>	The time window for this analysis run. For example, for a job scheduled to run at 05:00 UTC and a job that runs on 20/02/2020, <code>start_time:</code> is <code>2020-02-19T06:00:00Z</code> and <code>end_time:</code> is <code>2020-02-20T05:00:00Z</code>
<code>baseline_constraints:</code>	The local path of the baseline constraint file specified in <code>BaselineConfig.ConstraintResource.S3Uri</code> . This is available only if this parameter was specified in the <code>CreateMonitoringSchedule</code> request.

Parameter Name	Description
<code>baseline_statistics</code>	The local path to the baseline statistics file specified in <code>BaselineConfig.StatisticsResource.S3Uri</code> . This is available only if this parameter was specified in the <code>CreateMonitoringSchedule</code> request.

### Container Contract Outputs

The container can analyze the data available in the `*dataset_source*` path and write reports to the path in `*output_path*`. The container code can write any reports that suit your needs.

If you use the following structure and contract, certain output files are treated specially by SageMaker in the visualization and API . This applies only to tabular datasets.

### Output Files for Tabular Datasets

File Name	Description
<code>statistics.json</code>	This file is expected to have columnar statistics for each feature in the dataset that is analyzed. The schema for this file is available in the next section.
<code>constraints.json</code>	This file is expected to have the constraints on the features observed. The schema for this file is available in the next section.
<code>constraintsViolations.json</code>	This file is expected to have the list of violations found in this current set of data as compared to the baseline statistics and constraints file specified in the <code>baseline_constraints</code> and <code>baseline_statistics</code> path.

In addition, if the `publish_cloudwatch_metrics` value is "Enabled" container code can emit Amazon CloudWatch metrics in this location: `/opt/ml/output/metrics/cloudwatch`. The schema for these files is described in the following sections.

#### Topics

- [Schema for Statistics \(statistics.json file\) \(p. 1995\)](#)
- [Schema for Constraints \(constraints.json file\) \(p. 1997\)](#)

#### Schema for Statistics (statistics.json file)

The schema defined in the `statistics.json` file specifies the statistical parameters to be calculated for the baseline and data that is captured. It also configures the bucket to be used by `KLL`, a very compact quantiles sketch with lazy compaction scheme.

```
{
    "version": 0,
    # dataset level stats
    "dataset": {
        "item_count": number
    },
    # feature level stats
```

```

        ]
      }
    }
  }
}

```

```

        }
    },
    #provision for custom stats
]
}
}
```

## Notes

- The specified metrics are recognized by SageMaker in later visualization changes. The container can emit more metrics if required.
- [KLL sketch](#) is the recognized sketch. Custom containers can write their own representation, but it won't be recognized by SageMaker in visualizations.
- By default, the distribution is materialized in 10 buckets. You can't change this.

## Schema for Constraints (constraints.json file)

A constraints.json file is used to express the constraints that a dataset must satisfy. Amazon SageMaker Model Monitor containers can use the constraints.json file to evaluate datasets against. Prebuilt containers provide the ability to generate the constraints.json file automatically for a baseline dataset. If you bring your own container, you can provide it with similar abilities or you can create the constraints.json file in some other way. Here is the schema for the constraint file that the prebuilt container uses. Bring your own containers can adopt the same format or enhance it as required.

```
{
  "version" : 0,
  "features": [
    {
      "name": "string",
      "inferred_type": "Integral" | "Fractional" |
        | "String" | "Unknown",
      "completeness": number, # denotes observed non-null value percentage
      "num_constraints" : {
        "is_non_negative": boolean,
      },
      "string_constraints" : {
        "domains": [
          "list of",
          "observed values",
          "for small cardinality"
        ],
      },
      "monitoringConfigOverrides" : {
        #monitoringConfigOverrides
      }#feature
    }#features

    # options to control monitoring for this feature with monitoring jobs
    # See the following table for notes on what each constraint is doing.
  "monitoring_config": {
    "evaluate_constraints": "Enabled",
    "emit_metrics": "Enabled",
    "datatype_check_threshold": 0.1,
    "domain_content_threshold": 0.1,
    "distribution_constraints": {
      "perform_comparison": "Enabled",
      "comparison_threshold": 0.1,
      "comparison_method": "Simple" || "Robust"
    }
  }
}
```

```
}}#schema
```

## Monitoring Constraints

Constraint	Description
<code>evaluate_constraints</code>	<p>When <code>Enabled</code>, evaluates whether the current dataset being analyzed satisfies the constraints specified in the <code>constraints.json</code> file taken as a baseline.</p> <p>Valid values: <code>Enabled</code> or <code>Disabled</code></p> <p>Default: <code>Enabled</code></p>
<code>emit_metrics</code>	<p>When <code>Enabled</code>, emits CloudWatch metrics for the data contained in the file.</p> <p>Valid values: <code>Enabled</code> or <code>Disabled</code></p> <p>Default: <code>Enabled</code></p>
<code>datatype_check_threshold</code>	<p>If the threshold is above the value of the specified <code>datatype_check_threshold</code>, this causes a failure that is treated as a violation in the violation report. If the data types in the current execution are not the same as in the baseline dataset, this threshold is used to evaluate if it needs to be flagged as a violation.</p> <p>During the baseline step, the generated constraints suggest the inferred data type for each column. The <code>datatype_check_threshold</code> parameter can be tuned to adjust the threshold on when it is flagged as a violation.</p> <p>Valid values: float</p> <p>Default: 0.1</p>
<code>domain_content_threshold</code>	<p>If there are more unknown values for a String field in the current dataset than in the baseline dataset, this threshold can be used to dictate if it needs to be flagged as a violation.</p> <p>Valid values: float</p> <p>Default: 0.1</p>
<code>distribution_constraints</code>	<p><code>perform_comparison</code></p> <p>When <code>Enabled</code>, this flag instructs the code to perform a distribution comparison between the baseline distribution and the distribution observed for the current dataset.</p> <p>Valid values: <code>Enabled</code> or <code>Disabled</code></p> <p>Default: <code>Enabled</code></p>

Constraint	Description
	<p>comparison_threshold</p> <p>If the threshold is above the value set for the comparison_threshold, this causes a failure that is treated as a violation in the violation report. The distance is calculated by getting the maximum absolute difference between the cumulative distribution functions of two distributions.</p> <p>Valid values: float</p> <p>Default: 0.1</p>
	<p>comparison_method</p> <p>Whether to calculate linf_simple or linf_robust. The linf_simple is based on the maximum absolute difference between the cumulative distribution functions of two distributions. Calculating linf_robust is based on linf_simple, but is used when there are not enough samples. The linf_robust formula is based on the <a href="#">Two-sample Kolmogorov–Smirnov test</a>.</p> <p>Valid values: linf_simple or linf_robust.</p>

### CloudWatch Metrics for Bring Your Own Containers

If the publish\_cloudwatch\_metrics value is Enabled in the Environment map in the /opt/ml/processing/processingjobconfig.json file, the container code emits Amazon CloudWatch metrics in this location: /opt/ml/output/metrics/cloudwatch.

The schema for this file is closely based on the CloudWatch PutMetrics API. The namespace is not specified here. It defaults to /aws/sagemaker/Endpoint/data-metrics. However, you can specify dimensions. We recommend that you add the Endpoint and MonitoringSchedule dimensions at a minimum.

```
{
    "MetricName": "", # Required
    "Timestamp": "2019-11-26T03:00:00Z", # Required
    "Dimensions" : [{"Name": "Endpoint", "Value": "endpoint_0"}, {"Name": "MonitoringSchedule", "Value": "schedule_0"}]
    "Value": Float,
    # Either the Value or the StatisticValues field can be populated and not both.
    "StatisticValues": {
        "SampleCount": Float,
        "Sum": Float,
        "Minimum": Float,
        "Maximum": Float
    },
    "Unit": "Count", # Optional
}
```

## Create a Monitoring Schedule with an Amazon CloudFormation Custom Resource

To use Amazon CloudFormation to create a monitoring schedule, use an Amazon CloudFormation custom resource. The custom resource is in Python. To deploy it, see [Python Lambda deployment](#).

### Custom Resource

Start by adding a custom resource to your Amazon CloudFormation template. This points to a Amazon Lambda function that you create in the next step.

This resource enables you to customize the parameters for the monitoring schedule. You can add or remove more parameters by modifying the Amazon CloudFormation resource and the Lambda function in the following example resource.

```
{  
    "AWSTemplateFormatVersion": "2010-09-09",  
    "Resources": {  
        "MonitoringSchedule": {  
            "Type": "Custom::MonitoringSchedule",  
            "Version": "1.0",  
            "Properties": {  
                "ServiceToken": "arn:aws:lambda:us-west-2:111111111111:function:lambda-  
name",  
                "ScheduleName": "YourScheduleName",  
                "EndpointName": "YourEndpointName",  
                "BaselineConstraintsUri": "s3://your-baseline-constraints/  
constraints.json",  
                "BaselineStatisticsUri": "s3://your-baseline-stats/statistics.json",  
                "PostAnalyticsProcessorSourceUri": "s3://your-post-processor/  
postprocessor.py",  
                "RecordPreprocessorSourceUri": "s3://your-preprocessor/preprocessor.py",  
                "InputLocalPath": "/opt/ml/processing/endpointdata",  
                "OutputLocalPath": "/opt/ml/processing/localpath",  
                "OutputS3URI": "s3://your-output-uri",  
                "ImageURI": "11111111111.dkr.ecr.us-west-2.amazonaws.com/your-image",  
                "ScheduleExpression": "cron(0 * ? * * *)",  
                "PassRoleArn": "arn:aws:iam::111111111111:role/AmazonSageMaker-  
ExecutionRole"  
            }  
        }  
    }  
}
```

### Lambda Custom Resource Code

This Amazon CloudFormation custom resource uses the [Custom Resource Helper](#) Amazon library, which you can install with pip using `pip install crhelper`.

This Lambda function is invoked by Amazon CloudFormation during the creation and deletion of the stack. This Lambda function is responsible for creating and deleting the monitoring schedule and using the parameters defined in the custom resource described in the preceding section.

```
import boto3  
import botocore  
import logging  
  
from crhelper import CfnResource  
from botocore.exceptions import ClientError
```

```
logger = logging.getLogger(__name__)
sm = boto3.client('sagemaker')

# cfnhelper makes it easier to implement a CloudFormation custom resource
helper = CfnResource()

# CFN Handlers

def handler(event, context):
    helper(event, context)

@helper.create
def create_handler(event, context):

            raise e
```

## Register and Deploy Models with Model Registry

With the SageMaker model registry you can do the following:

- Catalog models for production.
- Manage model versions.
- Associate metadata, such as training metrics, with a model.
- Manage the approval status of a model.
- Deploy models to production.
- Automate model deployment with CI/CD.

Catalog models by creating model package groups that contain different versions of a model. You can create a model group that tracks all of the models that you train to solve a particular problem. You can then register each model you train and the model registry adds it to the model group as a new model version. A typical workflow might look like the following:

- Create a model group.
- Create an ML pipeline that trains a model. For information about SageMaker pipelines, see [Create and Manage SageMaker Pipelines \(p. 2201\)](#).
- For each run of the ML pipeline, create a model version that you register in the model group you created in the first step.

The following topics show how to use the model registry.

### Topics

- [Create a Model Group \(p. 2003\)](#)
- [Register a Model Version \(p. 2007\)](#)
- [View Model Groups and Versions \(p. 2008\)](#)
- [View the Details of a Model Version \(p. 2010\)](#)
- [Update the Approval Status of a Model \(p. 2012\)](#)
- [Deploy a Model in the Registry \(p. 2016\)](#)
- [Deploy a Model Version from a Different Account \(p. 2017\)](#)
- [View the Deployment History of a Model \(p. 2018\)](#)

## Create a Model Group

A model group contains a group of versioned models. Create a model group by using either the Amazon SDK for Python (Boto3) or in SageMaker Studio.

## Create a Model Package Group (Boto3)

To create a model group by using Boto3, call the `create_model_package_group` method, and specify a name and description as parameters. The following example shows how to create a model group. The response from the `create_model_package_group` call is the Amazon Resource Name (ARN) of the new model package group.

First, import the required packages and set up the SageMaker Boto3 client.

```
import time
import os
from sagemaker import get_execution_role, session
import boto3

region = boto3.Session().region_name

role = get_execution_role()

sm_client = boto3.client('sagemaker', region_name=region)
```

Now create the model group.

```
import time
model_package_group_name = "scikit-iris-detector-" + str(round(time.time()))
model_package_group_input_dict = {
    "ModelPackageName" : model_package_group_name,
    "ModelPackageGroupDescription" : "Sample model package group"
}

create_model_pacakge_group_response =
    sm_client.create_model_package_group(**model_package_group_input_dict)
print('ModelPackageGroup Arn :'
    '{}'.format(create_model_pacakge_group_response['ModelPackageGroupArn']))
```

## Create a Model Package Group (SageMaker Studio)

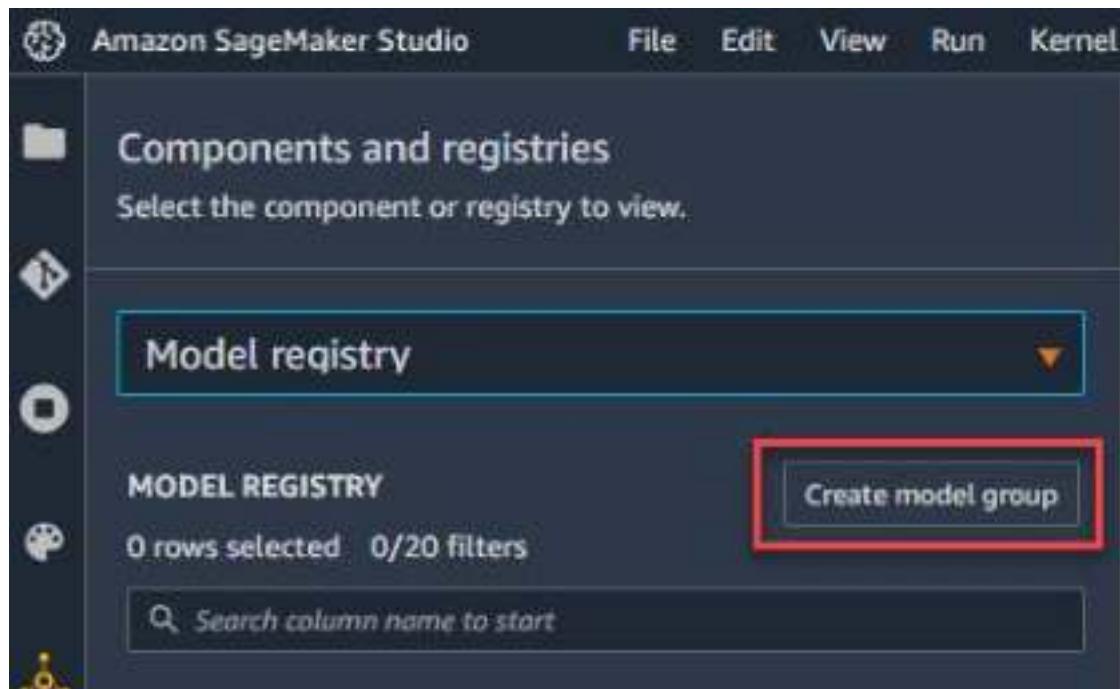

To create a model group in SageMaker Studio, complete the following steps.

1. Sign in to Studio. For more information, see [Onboard to Amazon SageMaker Studio \(p. 35\)](#).
2. In the left navigation pane, choose the **Components and registries** icon ().
3. Choose **Model registry**.

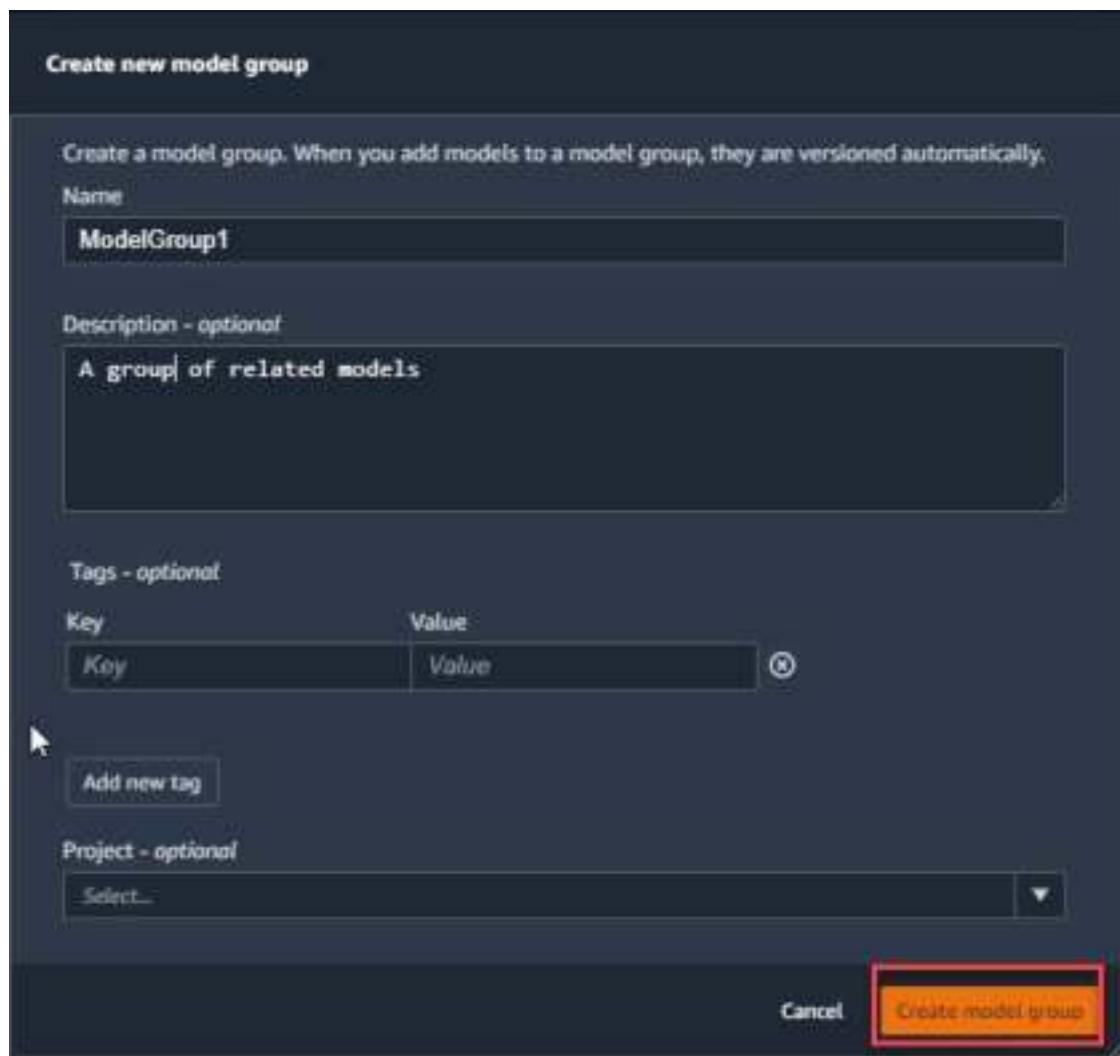

The screenshot shows the Amazon SageMaker Studio interface. At the top, there's a navigation bar with icons for Home, Studio, Projects, Data Wrangler, ML Flow, and Model Registry, followed by 'Amazon SageMaker Studio' and 'File Edit View Run Kernel'. Below this is a sidebar with icons for Home, Studio, Projects, Data Wrangler, ML Flow, and Model Registry. The main area is titled 'Components and registries' with the sub-section 'Select the component or registry to view.' A red box highlights the 'Model registry' button. Below this, there's a 'MODEL REGISTRY' section with a 'Create model group' button. A search bar says 'Search column name to start...'. A table lists three entries: 'ModelGroup1' created '1 hour ago', 'AbaloneMPG-16039329888329896' created '23 days ago', and 'scikit-iris-detector-1016' created '1 month ago'. The table has columns for 'Name' and 'Created'. At the bottom of the list, it says 'End of the list'.

Name	Created
ModelGroup1	1 hour ago
AbaloneMPG-16039329888329896	23 days ago
scikit-iris-detector-1016	1 month ago

4. Choose **Create model group**.

5. In the **Create new model group** dialog box, enter the following information:
  - For **Name**, enter the name of the new model group.
  - (Optional) For **Description**, enter a description for the model group.
  - (Optional) For **Tags**, enter any key-value pairs you want to associate with the model group. For information about using tags, see [Tagging Amazon resources](#) in the *Amazon General Reference*.
  - (Optional) For **Project**, choose a project with which to associate the model group. For information about projects, see [Automate MLOps with SageMaker Projects \(p. 2232\)](#).
6. Choose **Create model group**.

## Register a Model Version

You register a model by creating a model version that specifies the model group to which it belongs. A model version must include both the model artifacts (the trained weights of a model), and the inference code for the model. Create a model version by using either the Amazon SDK for Python (Boto3) or by creating a step in a SageMaker mode building pipeline.

### Register a Model Version (SageMaker Pipelines)

To register a model version by using a SageMaker model building pipeline, create a `RegisterModel` step in your pipeline. For information about creating `RegisterModel` step as part of a pipeline, see [Define a Pipeline \(p. 2201\)](#).

### Register a Model Version (Boto3)

To register a model version by using Boto3, call the `create_model_package` method.

First, you set up the parameter dictionary to pass to the `create_model_package` method.

```
modelpackage_inference_specification = {
    "InferenceSpecification": {
        "Containers": [
            {
                "Image": '257758044811.dkr.ecr.us-east-2.amazonaws.com/sagemaker-xgboost:1.2-1',
            }
        ],
        "SupportedContentTypes": [ "text/csv" ],
        "SupportedResponseMIMETypes": [ "text/csv" ],
    }
}

# Specify the model data
modelpackage_inference_specification["InferenceSpecification"]["Containers"][0]
["ModelDataUrl"] = model_url

create_model_package_input_dict = {
    "ModelPackageGroupName" : model_package_group_name,
    "ModelPackageDescription" : "Model to detect 3 different types of irises (Setosa, Versicolour, and Virginica)",
    "ModelApprovalStatus" : "PendingManualApproval"
}
create_model_package_input_dict.update(modelpackage_inference_specification)
```

Then you call the `create_model_package` method, passing in the parameter dictionary that you just set up.

```
create_mode_package_response =
sm_client.create_model_package(**create_model_package_input_dict)
model_package_arn = create_mode_package_response["ModelPackageArn"]
print('ModelPackage Version ARN : {}'.format(model_package_arn))
```

## View Model Groups and Versions

Model groups and versions help you organize your models. You can view a list of the model versions in a model group.

### View a List of Model Versions in a Group

You can view all of the model versions that are associated with a model group. If a model group represents all models that you train to address a specific ML problem, you can view all of those related models.

#### View a List of Model Versions in a Group (Boto3)

To view model versions associated with a model group by using Boto3, call the `list_model_packages` method, and pass the name of the model group as the value of the `ModelPackageGroupName` parameter. The following code lists the model versions associated with the model group you created in [Create a Model Package Group \(Boto3\) \(p. 2004\)](#).

```
sm_client.list_model_packages(ModelPackageGroupName=model_package_group_name)
```

#### View a List of Model Versions in a Group (SageMaker Studio)

To view a list of the model versions in a model group, complete the following steps.

1. Sign in to Studio. For more information, see [Onboard to Amazon SageMaker Studio \(p. 35\)](#).
2. In the left navigation pane, choose the **Components and registries** icon ( ).
3. Choose **Model registry**.

The screenshot shows the 'Components and registries' page in Amazon SageMaker Studio. The 'Model registry' section is highlighted with a red box. The interface includes a sidebar with icons for datasets, models, and more. The main area has a search bar and a table listing model groups. The table columns are 'Name' and 'Created'. The listed items are:

Name	Created
ModelGroup1	1 hour ago
AbaloneMPG-16039329888329896	23 days ago
scikit-iris-detector-1016	1 month ago

An 'End of the list' message is displayed at the bottom.

4. From the model groups list, choose the model group you want to view.
5. A new tab appears with a list of the model versions in the model group, as shown following.

The screenshot shows the 'ModelGroup1' tab. It has tabs for 'Versions' and 'Settings'. The 'Versions' tab is selected, showing a table of model versions. The table columns are 'Version', 'Stage', 'Status', 'Short description', and 'Modified by'. The data is as follows:

Version	Stage	Status	Short description	Modified by
1	prod	Approved		SageMakerUser
2	None	Pending		

## View the Details of a Model Version

You can view details of a specific model version by using either the Amazon SDK for Python (Boto3) or by using SageMaker Studio.

### View the Details of a Model Version (Boto3)

To view the details of a model version by using Boto3, complete the following steps.

1. Call the `list_model_packages` method to view the model versions in a model group.

```
sm_client.list_model_packages(ModelPackageGroupName="ModelGroup1")
```

The response is a list of model package summaries. You can get the Amazon Resource Name (ARN) of the model versions from this list.

```
{'ModelPackageSummaryList': [ {'ModelPackageGroupName': 'AbaloneMPG-16039329888329896',
  'ModelPackageVersion': 1,
  'ModelPackageArn': 'arn:aws:sagemaker:us-east-2:123456789012:model-package/
ModelGroup1/1',
  'ModelPackageDescription': 'TestMe',
  'CreationTime': datetime.datetime(2020, 10, 29, 1, 27, 46, 46000, tzinfo=tzlocal()),
  'ModelPackageStatus': 'Completed',
  'ModelApprovalStatus': 'Approved'}],
'ResponseMetadata': {'RequestId': '12345678-abcd-1234-abcd-aabbccddeeff',
'HTTPStatusCode': 200,
'HTTPHeaders': {'x-amzn-requestid': '12345678-abcd-1234-abcd-aabbccddeeff',
'content-type': 'application/x-amz-json-1.1',
'content-length': '349',
'date': 'Mon, 23 Nov 2020 04:56:50 GMT'},
'RetryAttempts': 0}}
```

2. Call `describe_model_package` to see the details of the model version. You pass in the ARN of a model version that you got in the output of the call to `list_model_packages`.

```
sm_client.describe_model_package(ModelPackageName="arn:aws:sagemaker:us-
east-2:123456789012:model-package/ModelGroup1/1")
```

The output of this call is a JSON object with the model version details.

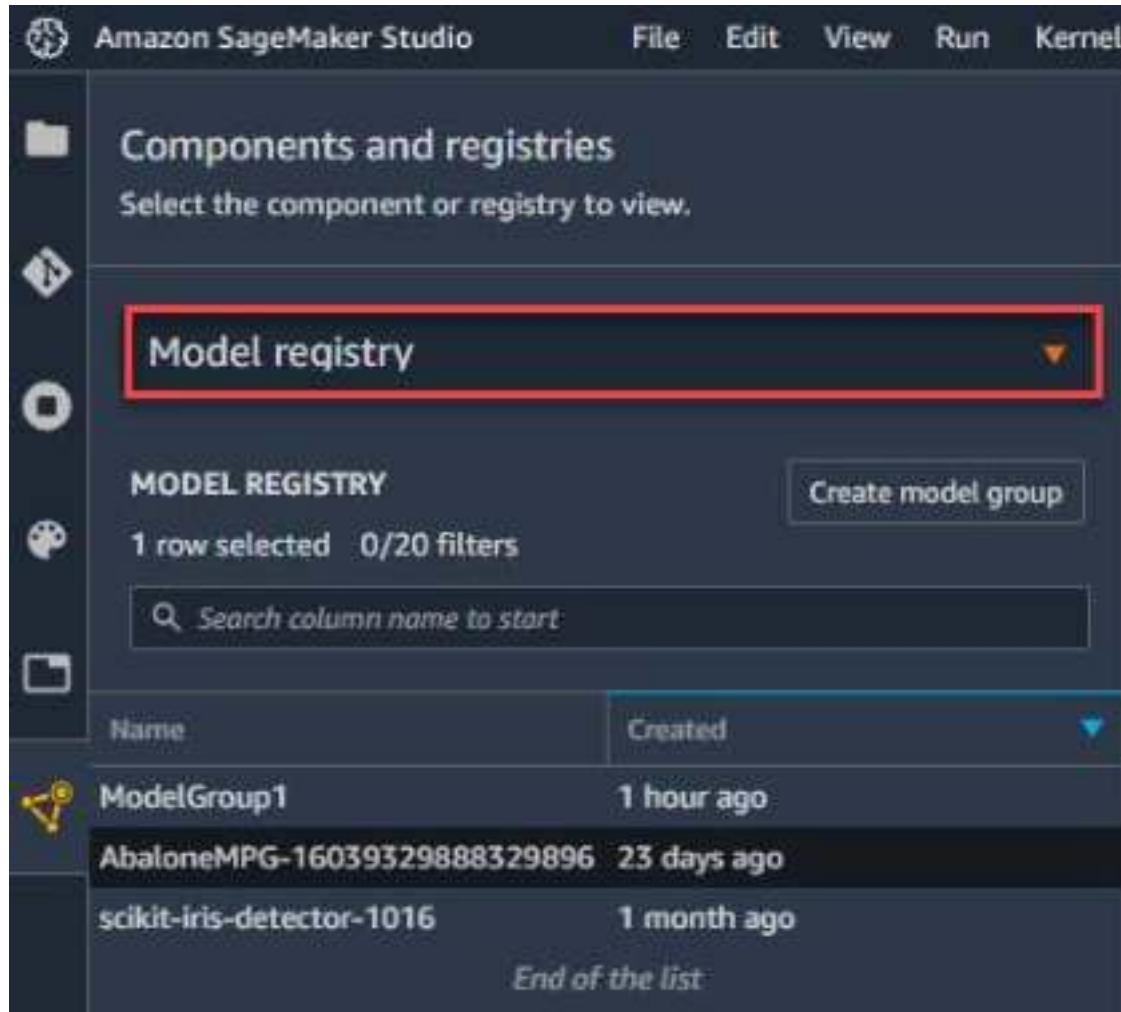

```
{'ModelPackageGroupName': 'ModelGroup1',
'ModelPackageVersion': 1,
'ModelPackageArn': 'arn:aws:sagemaker:us-east-2:123456789012:model-package/
ModelGroup1/1',
'ModelPackageDescription': 'Test Model',
'CreationTime': datetime.datetime(2020, 10, 29, 1, 27, 46, 46000, tzinfo=tzlocal()),
'InferenceSpecification': {'Containers': [{'Image': '257758044811.dkr.ecr.us-

```

## View the Details of a Model Version (SageMaker Studio)

To view the details of a model version in SageMaker Studio, complete the following steps.

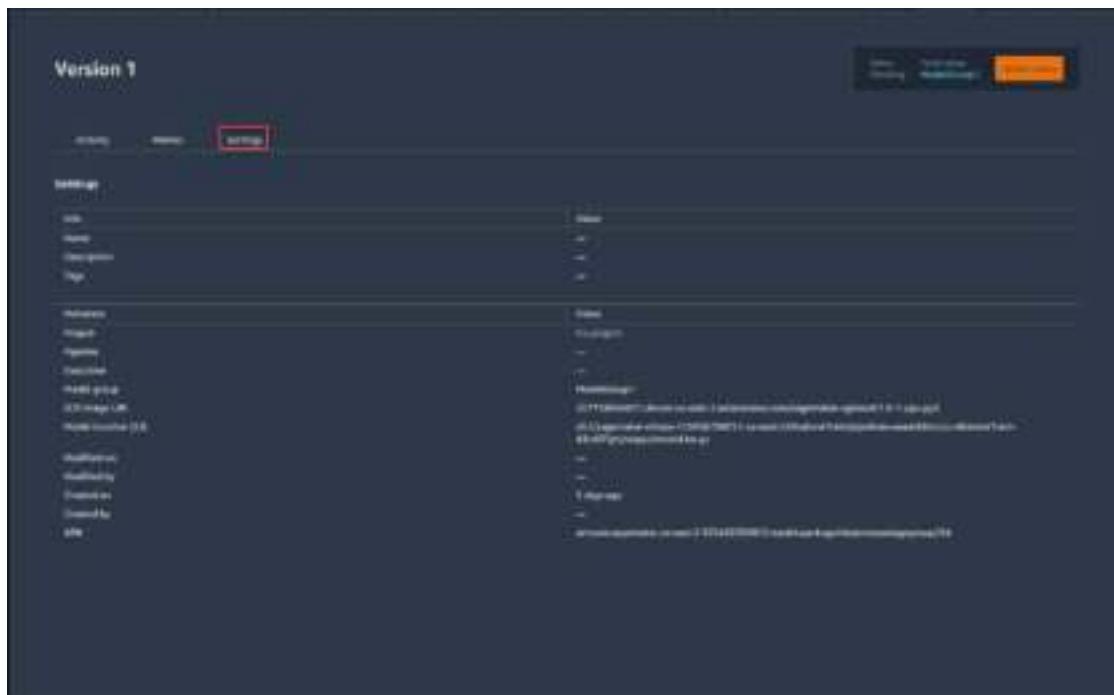

1. Sign in to Studio. For more information, see [Onboard to Amazon SageMaker Studio \(p. 35\)](#).
2. In the left navigation pane, choose the **Components and registries** icon (  ).
3. Choose **Model registry**.

4. From the model groups list, double-click the model group you want to view.
5. A new tab appears with a list of the model versions in the model group.

6. In the list of model versions, double-click the model version for which you want to view details.
  7. On the model version tab that opens, choose one of the following to see details about the model version:
    - **Activity** - Shows events for the model version, such as approval status updates.
    - **Metrics** - Shows quality metrics for the model. For metrics to appear, you must enable data capture for your model by using &SM; Model Monitor. For information about capturing data, see [Capture Data \(p. 1977\)](#).
    - **Settings** - Shows information such as the project that the model version is associated with, the pipeline that generated the model, the model group, and the model's location in Amazon S3.

## Update the Approval Status of a Model

After you create a model version, you typically want to evaluate its performance before you deploy it to a production endpoint. If it performs to your requirements, you can update the approval status of the model version to **Approved**. Setting the status to **Approved** can trigger CI/CD deployment for the model.

model. If the model version does not perform to your requirements, you can update the approval status to **Rejected**.

You can manually update the approval status of a model version after you register it, or you can create a condition step to evaluate the model when you create a SageMaker pipeline. For information about creating a condition step in a SageMaker pipeline, see [Pipeline Steps \(p. 2183\)](#).

When you use one of the SageMaker provided project templates and the approval status of a model version changes, the following action occurs. Only valid transitions are shown.

- **PendingManualApproval** to **Approved** – Triggers CI/CD deployment for the approved model version
- **PendingManualApproval** to **Rejected** – No action
- **Rejected** to **Approved** – Triggers CI/CD deployment for the approved model version
- **Approved** to **Rejected** – Triggers CI/CD to deploy the latest model version with an **Approved** status

You can update the approval status of a model version by using the Amazon SDK for Python (Boto3) or by using SageMaker Studio. You can also update the approval status of a model version as part of a condition step in a SageMaker pipeline. For information about using a model approval step in a SageMaker pipeline, see [SageMaker Pipelines Overview \(p. 2179\)](#).

## Update the Approval Status of a Model (Boto3)

When you created the model version in [Register a Model Version \(p. 2007\)](#), you set the `ModelApprovalStatus` to `PendingManualApproval`. You update the approval status for the model by calling `update_model_package`. Note that you can automate this process by writing code that, for example, sets the approval status of a model depending on the result of an evaluation of some measure of the model's performance. You can also create a step in a pipeline that automatically deploys a new model version when it is approved. The following code snippet shows how to manually change the approval status to `Approved`.

```
model_package_update_input_dict = {  
    "ModelPackageArn" : model_package_arn,  
    "ModelApprovalStatus" : "Approved"  
}  
model_package_update_response =  
    sm_client.update_model_package(**model_package_update_input_dict)
```

## Update the Approval Status of a Model (SageMaker Studio)

The following procedure shows how to manually change the approval status from `Approved` to `Rejected`.

1. Sign in to Studio. For more information, see [Onboard to Amazon SageMaker Studio \(p. 35\)](#).
2. In the left navigation pane, choose the **Components and registries** icon (  ).
3. Choose **Model registry**.

The screenshot shows the 'Components and registries' section of the Amazon SageMaker Studio interface. A red box highlights the 'Model registry' button. Below it, the 'MODEL REGISTRY' section displays a table with three rows:

Name	Created
ModelGroup1	1 hour ago
AbaloneMPG-16039329888329896	23 days ago
scikit-iris-detector-1016	1 month ago

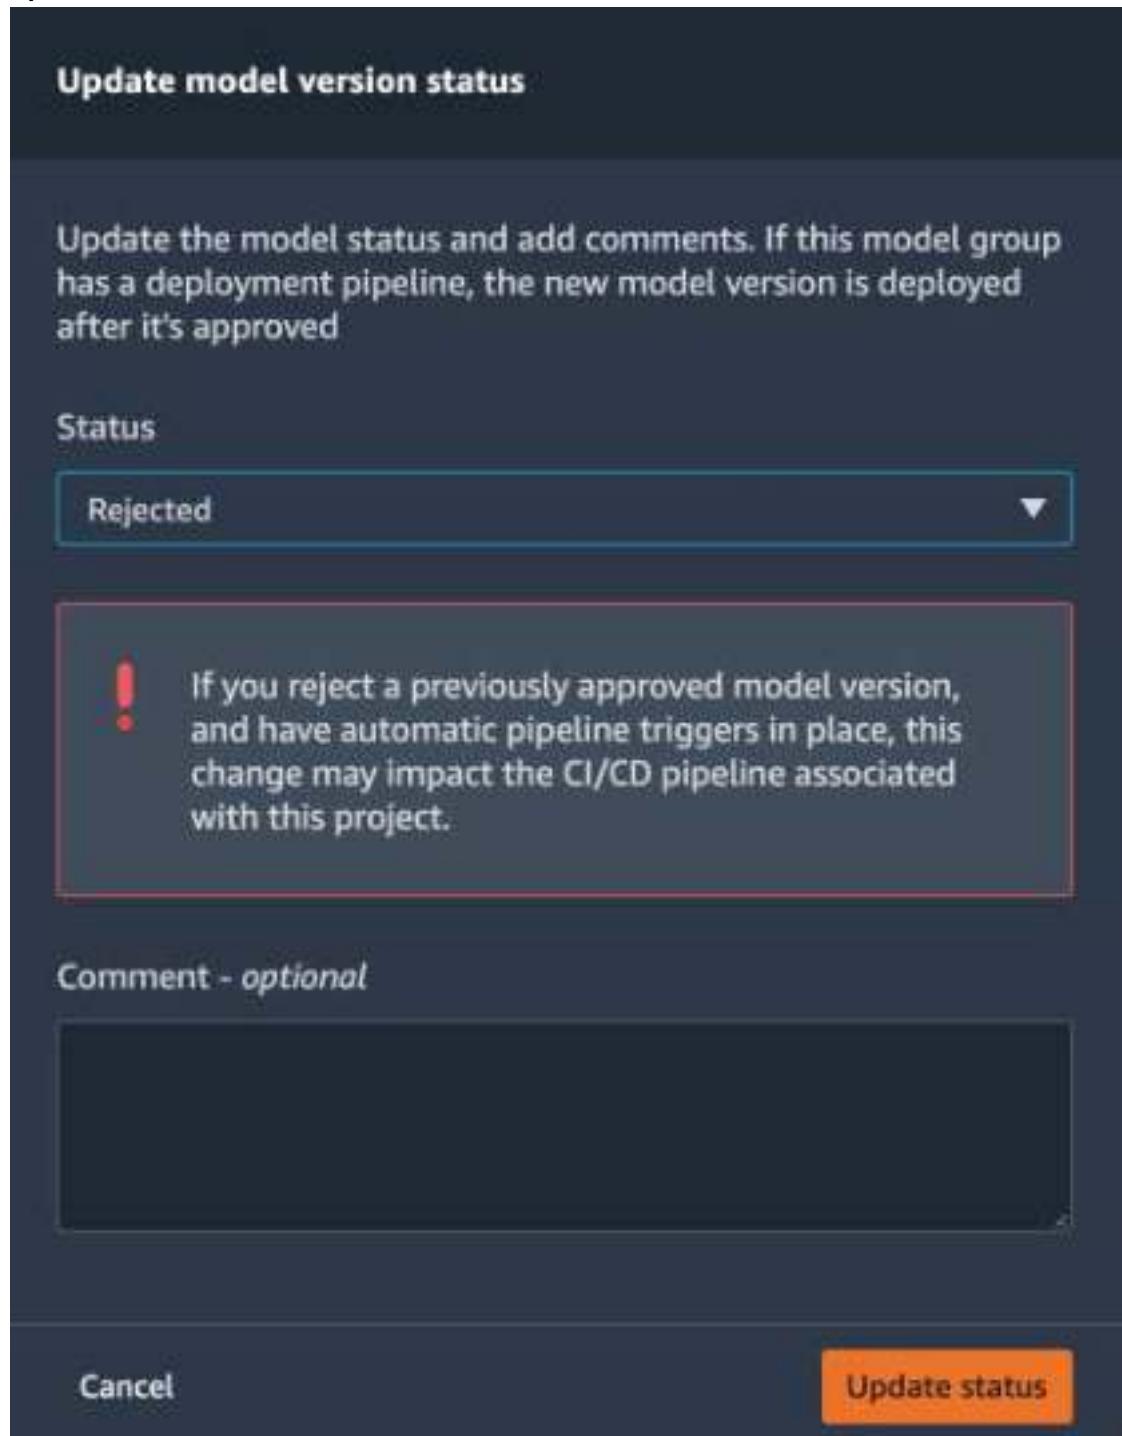

An 'End of the list' message is visible at the bottom right of the table area.

- From the model groups list, choose the model group you want to view. A new tab opens with a list of the model versions in the group.
- In the list of model versions, right-click the model version you want to update and choose **Update model version status**.

A context menu is open over a row in the 'MODEL REGISTRY' table. The 'Status' column for the first row is highlighted with a yellow background. The menu options include:

- Update model version status... (highlighted)
- Open model version
- Copy cell contents
- Shift+Right Click for Browser Menu

6. In the **Update model version status** dialog box, for **Status** choose **Rejected**, and then choose **Update status**.

# Deploy a Model in the Registry

After you register a model version and approve it for deployment, deploy it to a SageMaker endpoint for real-time inference.

When you create an MLOps project and choose an MLOps project template that includes model deployment, approved model versions in the model registry are automatically deployed to production. For information about using SageMaker MLOps projects, see [Automate MLOps with SageMaker Projects \(p. 2232\)](#).

## Deploy a Model in the Registry (Boto3)

To deploy a model version, complete the following steps:

1. Create a model object from the model version by calling `create_model`, passing the Amazon Resource Name (ARN) of the model version as the primary container for the model object. The following code snippet assumes you have already created the SageMaker Boto3 client `sm_client`, and that you have already created a model version with an ARN that you have stored in a variable named `model_version_arn`.

```
model_name = 'DEMO-modelregistry-model-' + strftime("%Y-%m-%d-%H-%M-%S", gmtime())
print("Model name : {}".format(model_name))
primary_container = {
    'ModelPackageName': model_version_arn,
}
create_model_response = sm_client.create_model(
    ModelName = model_name,
    ExecutionRoleArn = role,
    PrimaryContainer = primary_container
)
print("Model arn : {}".format(create_model_response["ModelArn"]))
```

2. Create an endpoint configuration by calling `create_endpoint_config`. The endpoint configuration specifies the number and type of Amazon EC2 instances to use for the endpoint.

```
endpoint_config_name = 'DEMO-modelregistry-EndpointConfig-' + strftime("%Y-%m-%d-%H-%M-%S", gmtime())
print(endpoint_config_name)
create_endpoint_config_response = sm_client.create_endpoint_config(
    EndpointConfigName = endpoint_config_name,
    ProductionVariants=[{
        'InstanceType':'ml.m4.xlarge',
        'InitialVariantWeight':1,
        'InitialInstanceCount':1,
        'ModelName':model_name,
        'VariantName':'AllTraffic'}])
```

3. Create the endpoint by calling `create_endpoint`.

```
endpoint_name = 'DEMO-modelregistry-endpoint-' + strftime("%Y-%m-%d-%H-%M-%S", gmtime())
print("EndpointName={}".format(endpoint_name))

create_endpoint_response = sm_client.create_endpoint(
    EndpointName=endpoint_name,
    EndpointConfigName=endpoint_config_name)
print(create_endpoint_response['EndpointArn'])
```

## Deploy a Model Version from a Different Account

Enable an Amazon account to deploy model versions that were created in a different account by adding a cross-account resource policy. For example, one team in your organization might be responsible for training models, and a different team is responsible for deploying and updating models. When you create resource policies, you apply the policy to the resource to which you want to grant access. For more information about cross-account resource policies in Amazon, see [Cross-account policy evaluation logic](#) in the *Amazon Identity and Access Management User Guide*.

To enable cross-account model deployment in SageMaker, you have to provide a cross-account resource policy for the model group that contains the model versions you want to deploy, the Amazon ECR repository where the inference image for the model group resides, and the Amazon S3 bucket where the model versions are stored. The following example creates cross-account policies for all three of these resources, and applies the policies to the resources.

```
import json

# cross account id to grant access to
cross_account_id = "123456789012"

# 1. Create policy for access to the ECR repository
ecr_repository_policy = {
    'Version': '2012-10-17',
    'Statement': [
        {
            'Sid': 'AddPerm',
            'Effect': 'Allow',
            'Principal': {
                'AWS': f'arn:aws:iam::{cross_account_id}:root'
            },
            'Action': ['ecr:*']
        }
    ]
}

# Convert the ECR policy from JSON dict to string
ecr_repository_policy = json.dumps(ecr_repository_policy)

# Set the new ECR policy
ecr = boto3.client('ecr')
response = ecr.set_repository_policy(
    registryId = account,
    repositoryName = 'decision-trees-sample',
    policyText = ecr_repository_policy
)

# 2. Create policy for access to the S3 bucket
bucket_policy = {
    'Version': '2012-10-17',
    'Statement': [
        {
            'Sid': 'AddPerm',
            'Effect': 'Allow',
            'Principal': {
                'AWS': f'arn:aws:iam::{cross_account_id}:root'
            },
            'Action': 's3:*',
            'Resource': f'arn:aws:s3:::{bucket}/*'
        }
    ]
}

# Convert the policy from JSON dict to string
bucket_policy = json.dumps(bucket_policy)

# Set the new policy
s3 = boto3.client('s3')
```

```
respose = s3.put_bucket_policy(
    Bucket = bucket,
    Policy = bucket_policy)

# 3. Create policy for access to the ModelPackageGroup
model_pacakge_group_policy = {
    'Version': '2012-10-17',
    'Statement': [
        {
            'Sid': 'AddPermModelPackageGroup',
            'Effect': 'Allow',
            'Principal': {
                'AWS': f'arn:aws:iam::{cross_account_id}:root'
            },
            'Action': ['sagemaker:DescribeModelPackageGroup'],
            'Resource': f'arn:aws:sagemaker:{region}:{account}:model-package-group/{model_package_group_name}'
        },
        {
            'Sid': 'AddPermModelPackageVersion',
            'Effect': 'Allow',
            'Principal': {
                'AWS': f'arn:aws:iam::{cross_account_id}:root'
            },
            'Action': ["sagemaker:DescribeModelPackage",
                       "sagemaker>ListModelPackages",
                       "sagemaker:UpdateModelPackage",
                       "sagemaker>CreateModel"],
            'Resource': f'arn:aws:sagemaker:{region}:{account}:model-package/{model_package_group_name}/*'
        }
    ]
}

# Convert the policy from JSON dict to string
model_pacakge_group_policy = json.dumps(model_pacakge_group_policy)

# Set the new policy
response = sm_client.put_model_package_group_policy(
    ModelPackageGroupName = model_package_group_name,
    ResourcePolicy = model_pacakge_group_policy)

print('ModelPackageGroupArn :')
print('{}'.format(create_model_pacakge_group_response['ModelPackageGroupArn']))
print("First Versioned ModelPackageArn: " + model_package_arn)
print("Second Versioned ModelPackageArn: " + model_package_arn2)

print("Success! You are all set to proceed for cross account deployment.")
```

The example assumes that you previously defined the following variables:

- `account` - The account of the authenticated caller.
- `bucket` - The S3 bucket where the model versions are stored.
- `sm_client` - A SageMaker Boto3 client.
- `model_package_group_name` - The model group to which you want to grant access.

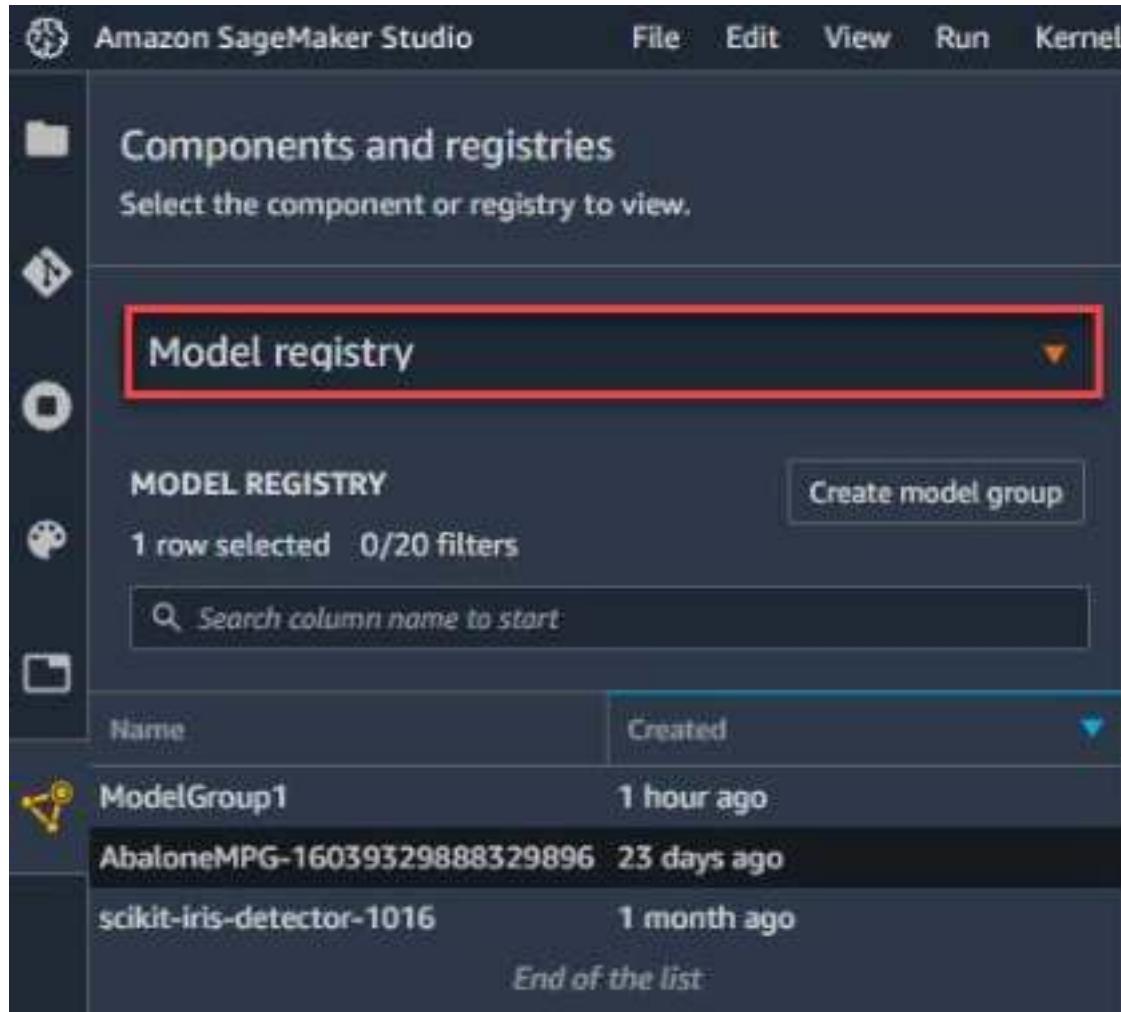

To be able to deploy a model that was created in a different account, the user must have a role that has access to SageMaker actions, such as a role with the `AmazonSageMakerFullAccess` managed policy. For information about SageMaker managed policies, see [Amazon Managed Policies for Amazon SageMaker \(p. 2464\)](#).

## View the Deployment History of a Model

View the deployments for a model version SageMaker Studio by opening the tab for that model version.

### View the deployment history for a model version

1. Sign in to Studio. For more information, see [Onboard to Amazon SageMaker Studio \(p. 35\)](#).
2. In the left navigation pane, choose the **Components and registries** icon (  ).
3. Choose **Model registry**.

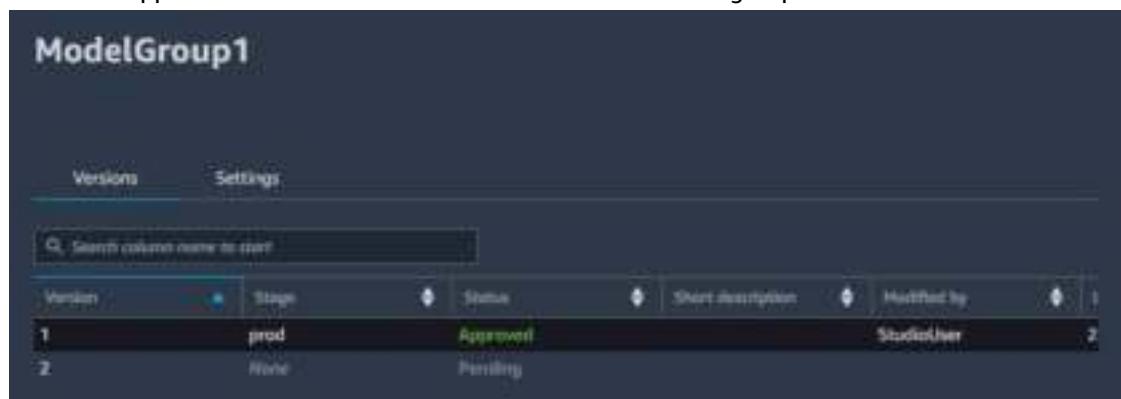

The screenshot shows the 'Components and registries' page in Amazon SageMaker Studio. On the left, there's a sidebar with icons for Model Registry, Model Group, Pipeline, and Data Store. The main area has a title 'Components and registries' and a sub-instruction 'Select the component or registry to view.' Below this, a section titled 'Model registry' is highlighted with a red box. To its right is a 'Create model group' button. The 'MODEL REGISTRY' section displays a table with three rows of data:

Name	Created
ModelGroup1	1 hour ago
AbaloneMPG-16039329888329896	23 days ago
scikit-iris-detector-1016	1 month ago

An 'End of the list' message is at the bottom.

4. From the model groups list, choose the model group you want to view.
5. A new tab appears with a list of the model versions in the model group.

The screenshot shows the 'ModelGroup1' details page. At the top, there are tabs for 'Versions' and 'Settings'. The 'Versions' tab is selected. Below it is a search bar with placeholder text 'Search column name to start...'. The main area is a table titled 'ModelGroup1' with two rows of data:

Version	Stage	Status	Short description	Modified by	
1	prod	Approved		StudioUser	2
2	None	Pending			

6. In the list of model versions, double-click the model version for which you want to view details.

The screenshot shows the 'ModelGroup1' interface. At the top, there are tabs for 'Versions' and 'Settings'. Below the tabs is a search bar with placeholder text 'Search column name or content...'. A table follows, with columns: Version, Stage, Status, Short description, Modified by, and Last modified. The table has two rows:

Version	Stage	Status	Short description	Modified by	Last modified
1	prod	Approved		StudioUser	2023-09-18 10:00:00
2	None	Pending			2023-09-18 10:00:00

7. On the model version tab that opens, choose **Activity**. Deployments for the model version appear as events in the activity list with an **Event type** of **ModelDeployment**.

The screenshot shows the 'Version 1' activity log. At the top, it displays basic information: Status (Approved), Pipeline (MyProject-Neu27-pipeline), Execution (execution-123456789...), Last step (prod), Model group (ModelGroup1), and Version (Version 1). Below this is a navigation bar with tabs: Activity, Metrics, and Settings. The 'Activity' tab is selected. The activity log table has columns: Event type, Event, Component, Modified by, and Last run. It lists several events:

Event type	Event	Component	Modified by	Last run
ModelDeployment	Deployed to stage: prod	prod		20 hours
ModelDeployment	Deployed to stage: staging	staging		22 hours
Approval	Status updated to Approved		unathic-601	22 hours
Approval	Status updated to PendingManualApproval			22 hours

# Compile and Deploy Models with Neo

Neo is a capability of Amazon SageMaker that enables machine learning models to train once and run anywhere in the cloud and at the edge.

If you are a first time user of SageMaker Neo, we recommend you check out the [Getting Started with Edge Devices](#) section to get step-by-step instructions on how to compile and deploy to an edge device.

## What is SageMaker Neo?

Generally, optimizing machine learning models for inference on multiple platforms is difficult because you need to hand-tune models for the specific hardware and software configuration of each platform. If you want to get optimal performance for a given workload, you need to know the hardware architecture, instruction set, memory access patterns, and input data shapes, among other factors. For traditional software development, tools such as compilers and profilers simplify the process. For machine learning, most tools are specific to the framework or to the hardware. This forces you into a manual trial-and-error process that is unreliable and unproductive.

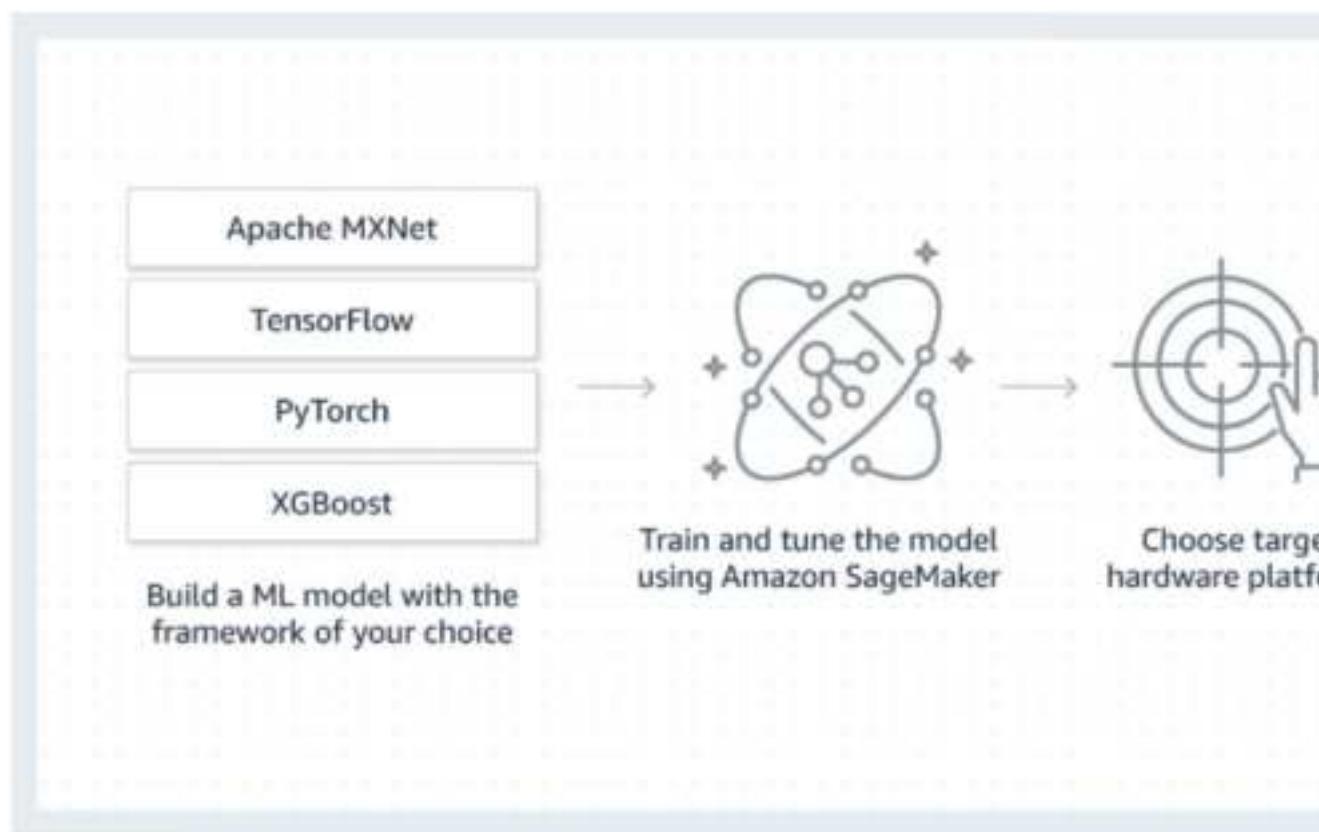

Neo automatically optimizes Gluon, Keras, MXNet, PyTorch, TensorFlow, TensorFlow-Lite, and ONNX models for inference on Android, Linux, and Windows machines based on processors from Ambarella, ARM, Intel, Nvidia, NXP, Qualcomm, Texas Instruments, and Xilinx. Neo is tested with computer vision models available in the model zoos across the frameworks. SageMaker Neo supports compilation and deployment for two main platforms: cloud instances (including Inferentia) and edge devices.

For more information about supported frameworks and cloud instance types you can deploy to, see [Supported Instance Types and Frameworks \(p. 2036\)](#) for cloud instances.

For more information about supported frameworks, edge devices, operating systems, chip architectures, and common machine learning models tested by SageMaker Neo for edge devices, see [Supported Frameworks, Devices, Systems, and Architectures \(p. 2063\)](#) for edge devices.

## How it Works

Neo consists of a compiler and a runtime. First, the Neo compilation API reads models exported from various frameworks. It converts the framework-specific functions and operations into a framework-agnostic intermediate representation. Next, it performs a series of optimizations. Then it generates binary code for the optimized operations, writes them to a shared object library, and saves the model definition and parameters into separate files. Neo also provides a runtime for each target platform that loads and executes the compiled model.

You can create a Neo compilation job from either the SageMaker console, the Amazon Command Line Interface (Amazon CLI), a Python notebook, or the SageMaker SDK. For information on how to compile a model, see [Use Neo to Compile a Model \(p. 2023\)](#). With a few CLI commands, an API invocation, or a few clicks, you can convert a model for your chosen platform. You can deploy the model to a SageMaker endpoint or on an Amazon IoT Greengrass device quickly.

Neo can optimize models with parameters either in FP32 or quantized to INT8 or FP16 bit-width.

## Neo Sample Notebooks

For sample notebooks that use SageMaker Neo to train, compile, optimize, and deploy machine learning models to make inferences, see:

- [MNIST Training, Compilation and Deployment with MXNet Module](#)
- [MNIST Training, Compilation and Deployment with Tensorflow Module](#)
- [Deploying pre-trained PyTorch vision models with SageMaker Neo](#)
- [Model Optimization with an Image Classification Example](#)
- [Model Optimization with XGBoost Example](#)

For instructions on how to run these example notebooks in SageMaker, see [Example Notebooks \(p. 131\)](#). If you need instructions on how to create a notebook instance to run these examples, see [Use Amazon SageMaker Notebook Instances \(p. 120\)](#). To navigate to the relevant example in your notebook instance, choose the **Amazon SageMaker Examples** tab to see a list of all of the SageMaker samples. To open a notebook, choose its **Use** tab, then choose **Create copy**.

## Use Neo to Compile a Model

This section shows how to create, describe, stop, and list compilation jobs. The following options are available in Amazon SageMaker Neo for managing the compilation jobs for machine learning models: the Neo CLI, the Amazon SageMaker console, or the Amazon SageMaker SDK.

### Topics

- [Prepare Model for Compilation \(p. 2023\)](#)
- [Compile a Model \(Amazon Command Line Interface\) \(p. 2028\)](#)
- [Compile a Model \(Amazon SageMaker Console\) \(p. 2031\)](#)
- [Compile a Model \(Amazon SageMaker SDK\) \(p. 2035\)](#)

## Prepare Model for Compilation

SageMaker Neo requires machine learning models satisfy specific input data shape. The input shape required for compilation depends on the deep learning framework you use. Once your model input shape is correctly formatted, save your model according to the requirements below. Once you have a saved model, compress the model artifacts.

### Topics

- [What input data shapes does SageMaker Neo expect? \(p. 2023\)](#)
- [Saving Models for SageMaker Neo \(p. 2024\)](#)

## What input data shapes does SageMaker Neo expect?

Before you compile your model, make sure your model is formatted correctly. Neo expects the name and shape of the expected data inputs for your trained model with JSON format or list format. The expected inputs are framework specific.

Below are the input shapes SageMaker Neo expects:

### Keras

Specify the name and shape (NCHW format) of the expected data inputs using a dictionary format for your trained model. Note that while Keras model artifacts should be uploaded in NHWC (channel-last) format, DataInputConfig should be specified in NCHW (channel-first) format. The dictionary formats required are as follows:

- For one input: `{'input_1':[1,3,224,224]}`
- For two inputs: `{'input_1': [1,3,224,224], 'input_2':[1,3,224,224]}`

### MXNet/ONNX

Specify the name and shape (NCHW format) of the expected data inputs using a dictionary format for your trained model. The dictionary formats required are as follows:

- For one input: `{'data':[1,3,1024,1024]}`
- For two inputs: `{'var1': [1,1,28,28], 'var2':[1,1,28,28]}`

## PyTorch

Specify the name and shape (NCHW format) of the expected data inputs using a dictionary format for your trained model. Alternatively, you can specify the shape only using a list format. The dictionary formats required are as follows:

- For one input in dictionary format: `{'input0':[1,3,224,224]}`
- For one input in list format: `[[1,3,224,224]]`
- For two inputs in dictionary format: `{'input0':[1,3,224,224], 'input1':[1,3,224,224]}`
- For two inputs in list format: `[[1,3,224,224], [1,3,224,224]]`

## TensorFlow

Specify the name and shape (NHWC format) of the expected data inputs using a dictionary format for your trained model. The dictionary formats required are as follows:

- For one input: `{'input':[1,1024,1024,3]}`
- For two inputs: `{'data1': [1,28,28,1], 'data2':[1,28,28,1]}`

## TFLite

Specify the name and shape (NHWC format) of the expected data inputs using a dictionary format for your trained model. The dictionary formats required are as follows:

- For one input: `{'input':[1,224,224,3]}`

## XGBoost

An input data name and shape are not needed.

## Saving Models for SageMaker Neo

The following code examples show how to save your model to make it compatible with Neo. Models must be packaged as compressed tar files (\*.tar.gz).

### Keras

Keras models require one model definition file (.h5).

There are two options for saving your Keras model in order to make it compatible for SageMaker Neo:

1. Export to .h5 format with `model.save("<model-name>", save_format="h5")`.
2. Freeze the SavedModel after exporting.

Below is an example of how to export a `tf.keras` model as a frozen graph (option two):

```
import os
import tensorflow as tf
from tensorflow.keras.applications.resnet50 import ResNet50
from tensorflow.keras import backend

tf.keras.backend.set_learning_phase(0)
model = tf.keras.applications.ResNet50(weights='imagenet', include_top=False,
    input_shape=(224, 224, 3), pooling='avg')
model.summary()
```

```
# Save as a SavedModel
export_dir = 'saved_model/'
model.save(export_dir, save_format='tf')

# Freeze saved model
input_node_names = [inp.name.split(":")[0] for inp in model.inputs]
output_node_names = [output.name.split(":")[0] for output in model.outputs]
print("Input names: ", input_node_names)
with tf.Session() as sess:
    loaded = tf.saved_model.load(sess, export_dir=export_dir, tags=["serve"])
    frozen_graph = tf.graph_util.convert_variables_to_constants(sess,
                                                               sess.graph.as_graph_def(),
                                                               output_node_names)
    tf.io.write_graph(graph_or_graph_def=frozen_graph, logdir=".", name="frozen_graph.pb",
                     as_text=False)
```

### Warning

Do not export your model with the `SavedModel` class using `model.save(<path>, save_format='tf')`. This format is suitable for training, but it is not suitable for inference.

## MXNet

MXNet models must be saved as a single symbol file `*-symbol.json` and a single parameter `*.params` files.

### Gluon Models

Define the neural network using the `HybridSequential` Class. This will run the code in the style of symbolic programming (as opposed to imperative programming).

```
from mxnet import nd, sym
from mxnet.gluon import nn

def get_net():
    net = nn.HybridSequential() # Here we use the class HybridSequential.
    net.add(nn.Dense(256, activation='relu'),
           nn.Dense(128, activation='relu'),
           nn.Dense(2))
    net.initialize()
    return net

# Define an input to compute a forward calculation.
x = nd.random.normal(shape=(1, 512))
net = get_net()

# During the forward calculation, the neural network will automatically infer
# the shape of the weight parameters of all the layers based on the shape of
# the input.
net(x)

# hybridize model
net.hybridize()

# export model
net.export('<model_name>') # this will create model-symbol.json and model-0000.params
                           # files

for name in ["<model_name>-0000.params", "<model_name>-symbol.json"]:
    tar.add(name)
tar.close()
```

For more information about hybridizing models, see the [MXNet hybridize documentation](#).

## Gluon Model Zoo (GluonCV)

GluonCV model zoo models come pre-hybridized. So you can just export them.

```
import numpy as np
import mxnet as mx
import gluoncv as gcv

net = gcv.model_zoo.get_model('<model_name>', pretrained=True)
net.export('<model_name>')
tar = tarfile.open("<model_name>.tar.gz", "w:gz")
>>>>> ngl_neo_framework_model_saving_how_to

for name in ["<model_name>-0000.params", "<model_name>-symbol.json"]:
    tar.add(name)
tar.close()
```

## Non Gluon Models

All non-Gluon models when saved to disk use `*-symbol` and `*.params` files. They are therefore already in the correct format for Neo.

```
# Pass the following 3 parameters: sym, args, aux
mx.model.save_checkpoint('<model_name>', 0, sym, args, aux) # this will create
# <model_name>-symbol.json and <model_name>-0000.params files

tar = tarfile.open("<model_name>.tar.gz", "w:gz")

for name in ["<model_name>-0000.params", "<model_name>-symbol.json"]:
    tar.add(name)
tar.close()
```

## PyTorch

PyTorch models must be saved as a definition file (`.pt` or `.pth`) with input datatype of `float32`.

To save your model, use `torch.jit.trace` followed by `torch.save`. This will save an object to a disk file and by default uses python pickle (`pickle_module=pickle`) to save the objects and some metadata. Next, convert the saved model to a compressed tar file.

```
import torchvision
import torch

model = torchvision.models.resnet18(pretrained=True)
model.eval()
inp = torch.rand(1, 3, 224, 224)
model_trace = torch.jit.trace(model, inp)

# Save your model. The following code saves it with the .pth file extension
model_trace.save('model.pth')

# Save as a compressed tar file
with tarfile.open('model.tar.gz', 'w:gz') as f:
    f.add('model.pth')
f.close()
```

## TensorFlow

TensorFlow requires one `.pb` or one `.pbtxt` file and a `variables` directory that contains variables. For frozen models, only one `.pb` or `.pbtxt` file is required.

## Pre-Trained Model

The following code example shows how to use the tar Linux command to compress your model. Run the following in your terminal or in a Jupyter notebook (if you use a Jupyter notebook, insert the ! magic command at the beginning of the statement):

```
import os
import tensorflow as tf

# Download SSD_Mobilenet trained model
wget http://download.tensorflow.org/models/object_detection/
ssd_mobilenet_v2_coco_2018_03_29.tar.gz

# unzip the compressed tar file
tar xvf ssd_mobilenet_v2_coco_2018_03_29.tar.gz

# Change into the directory where the model is stored
cd ssd_mobilenet_v2_coco_2018_03_29

# Compress the tar file and save it in a directory called 'saved_model'
tar czvf panorama-model.tar.gz saved_model
```

The command flags used in this example accomplish the following:

- c: Create an archive
- z: Compress the archive with gzip
- v: Display archive progress
- f: Specify the filename of the archive

## Built-In Estimators

Built-in estimators are either made by framework-specific containers or algorithm-specific containers. Estimator objects for both the built-in algorithm and framework-specific estimator saves the model in the correct format for you when you train the model using the built-in .fit method.

For example, you can use a `sagemaker.TensorFlow` to define a TensorFlow estimator:

```
from sagemaker.tensorflow import TensorFlow

estimator = TensorFlow(entry_point='mnist.py',
                      role=role,
                      framework_version='1.15.3',
                      py_version='py3',
                      training_steps=1000,
                      evaluation_steps=100,
                      instance_count=2,
                      instance_type='ml.c4.xlarge')
```

Then train the model with `.fit` built-in method:

```
estimator.fit(inputs)
```

Before finally compiling model with the build in `compile_model` method:

```
# Specify output path of the compiled model
output_path = '/'.join(estimator.output_path.split('/')[-1:])

# Compile model
optimized_estimator = estimator.compile_model(target_instance_family='ml_c5',
```

```
    input_shape={'data':[1, 784]}, # Batch size 1, 3 channels,  
224x224 Images.  
    output_path=output_path,  
    framework='tensorflow', framework_version='1.15.3')
```

You can also use the `sagemaker.estimator.Estimator` Class to initialize an estimator object for training and compiling a built-in algorithm with the `compile_model` method from the SageMaker Python SDK:

```
from sagemaker.image_uris import retrieve  
aws_region = sagemaker_session.boto_region_name  
  
# Specify built-in algorithm training image  
training_image = retrieve(framework='image-classification',  
                           region=aws_region, image_scope='training')  
  
training_image = retrieve(framework='image-classification', region=aws_region,  
                           image_scope='training')  
  
# Create estimator object for training  
estimator = sagemaker.estimator.Estimator(image_uri=training_image,  
                                           role=role,  
                                           instance_count=1,  
                                           instance_type='ml.p3.8xlarge',  
                                           volume_size = 50,  
                                           max_run = 360000,  
                                           input_mode= 'File',  
                                           output_path=s3_training_output_location,  
                                           base_job_name='image-classification-training'  
)  
  
# Setup the input data_channels to be used later for training.  
  
train_data = sagemaker.inputs.TrainingInput(s3_training_data_location,  
                                             content_type='application/x-recordio',  
                                             s3_data_type='S3Prefix')  
validation_data = sagemaker.inputs.TrainingInput(s3_validation_data_location,  
                                                content_type='application/x-recordio',  
                                                s3_data_type='S3Prefix')  
data_channels = {'train': train_data, 'validation': validation_data}  
  
# Train model  
estimator.fit(inputs=data_channels, logs=True)  
  
# Compile model with Neo  
  
optimized_estimator = estimator.compile_model(target_instance_family='ml_c5',  
                                               input_shape={'data':[1, 3, 224, 224],  
'softmax_label':[1]},  
                                               output_path=s3_compilation_output_location,  
                                               framework='mxnet',  
                                               framework_version='1.7')
```

For more information about compiling models with the SageMaker Python SDK, see [Compile a Model \(Amazon SageMaker SDK\) \(p. 2035\)](#).

## Compile a Model (Amazon Command Line Interface)

This section shows how to manage Amazon SageMaker Neo compilation jobs for machine learning models using Amazon Command Line Interface (CLI). You can create, describe, stop, and list the compilation jobs.

## 1. Create a Compilation Job

With the [CreateCompilationJob](#) API operation, you can specify the data input format, the S3 bucket in which to store your model, the S3 bucket to which to write the compiled model, and the target hardware device or platform.

The following table demonstrates how to configure `CreateCompilationJob` API based on whether your target is a device or a platform.

### Device Example

```
{
    "CompilationJobName": "neo-compilation-job-demo",
    "RoleArn": "arn:aws:iam::your-account:role/service-role/AmazonSageMaker-ExecutionRole-yyyymmddThhmmss",
    "InputConfig": {
        "S3Uri": "s3://<your-bucket>/sagemaker/neo-compilation-job-demo-data/train",
        "DataInputConfig": "{ 'data': [1,3,1024,1024] }",
        "Framework": "MXNET"
    },
    "OutputConfig": {
        "S3OutputLocation": "s3://<your-bucket>/sagemaker/neo-compilation-job-demo-data/compile",
        # A target device specification example for a ml_c5 instance family
        "TargetDevice": "ml_c5"
    },
    "StoppingCondition": {
        "MaxRuntimeInSeconds": 300
    }
}
```

You can optionally specify the framework version you used with the `FrameworkVersion` field if you used the PyTorch framework to train your model and your target device is a `ml_*` target.

```
{
    "CompilationJobName": "neo-compilation-job-demo",
    "RoleArn": "arn:aws:iam::your-account:role/service-role/AmazonSageMaker-ExecutionRole-yyyymmddThhmmss",
    "InputConfig": {
        "S3Uri": "s3://<your-bucket>/sagemaker/neo-compilation-job-demo-data/train",
        "DataInputConfig": "{ 'data': [1,3,1024,1024] }",
        "Framework": "PYTORCH",
        # The FrameworkVersion field is only supported when compiling for PyTorch
        # framework and ml_* targets,
        # excluding ml_inf. Supported values are 1.4 or 1.5 or 1.6 . Default is
        1.6
        "FrameworkVersion": "1.6"
    },
    "OutputConfig": {
        "S3OutputLocation": "s3://<your-bucket>/sagemaker/neo-compilation-job-demo-data/compile",
        # A target device specification example for a ml_c5 instance family
        "TargetDevice": "ml_c5",
        # When compiling for ml_* instances using PyTorch framework, use the
        "CompilerOptions" field in
        # OutputConfig to provide the correct data type ("dtype") of the model's
        # input. Default assumed is "float32"
        "CompilerOptions": "{ 'dtype': 'long' }"
    },
    "StoppingCondition": {
        "MaxRuntimeInSeconds": 300
    }
}
```

```
    }
}
```

**Note**

This API field is only supported for PyTorch.

Platform Example

```
{
    "CompilationJobName": "neo-test-compilation-job",
    "RoleArn": "arn:aws:iam::<your-account>:role/service-role/AmazonSageMaker-
ExecutionRole-yyyymmddThhmmss",
    "InputConfig": {
        "S3Uri": "s3://<your-bucket>/sagemaker/neo-compilation-job-demo-data/
train",
        "DataInputConfig": "{ 'data': [1,3,1024,1024] }",
        "Framework": "MXNET"
    },
    "OutputConfig": {
        "S3OutputLocation": "s3://<your-bucket>/sagemaker/neo-compilation-job-demo-
data/compile",
        "# A target platform configuration example for a p3.2xlarge instance
        "TargetPlatform": {
            "Os": "LINUX",
            "Arch": "X86_64",
            "Accelerator": "NVIDIA"
        },
        "CompilerOptions": "{ 'cuda-ver': '10.0', 'trt-ver': '6.0.1', 'gpu-code':
'sm_70' }"
    },
    "StoppingCondition": {
        "MaxRuntimeInSeconds": 300
    }
}
```

**Note**

For the `OutputConfig` API operation, the `TargetDevice` and `TargetPlatform` API operations are mutually exclusive. You have to choose one of the two options.

To find the JSON string examples of `DataInputConfig` depending on frameworks, see [What input data shapes Neo expects](#).

For more information about setting up the configurations, see the [InputConfig](#), [OutputConfig](#), and [TargetPlatform](#) API operations in the SageMaker API reference.

2. After you configure the JSON file, run the following command to create the compilation job:

```
aws sagemaker create-compilation-job \
--cli-input-json file://job.json \
--region us-west-2

# You should get CompilationJobArn
```

3. Describe the compilation job by running the following command:

```
aws sagemaker describe-compilation-job \
--compilation-job-name $JOB_NM \
--region us-west-2
```

4. Stop the compilation job by running the following command:

```
aws sagemaker stop-compilation-job \
--compilation-job-name $JOB_NM \
--region us-west-2

# There is no output for compilation-job operation
```

5. List the compilation job by running the following command:

```
aws sagemaker list-compilation-jobs \
--region us-west-2
```

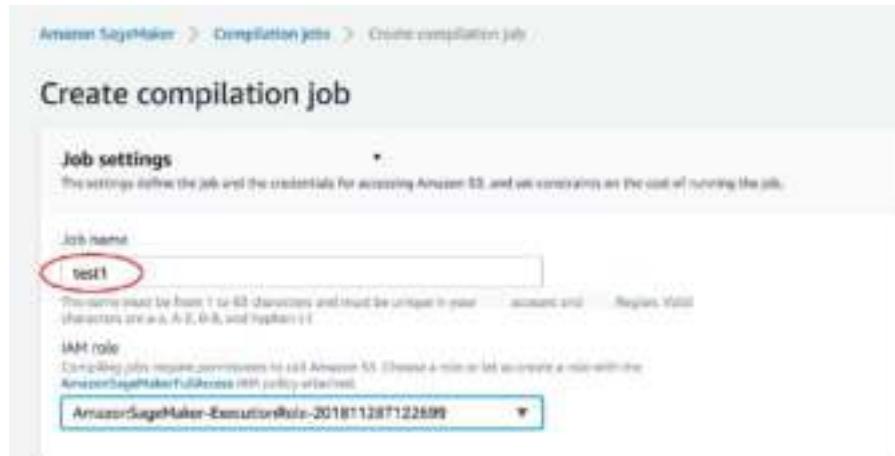

## Compile a Model (Amazon SageMaker Console)

You can create an Amazon SageMaker Neo compilation job in the Amazon SageMaker console.

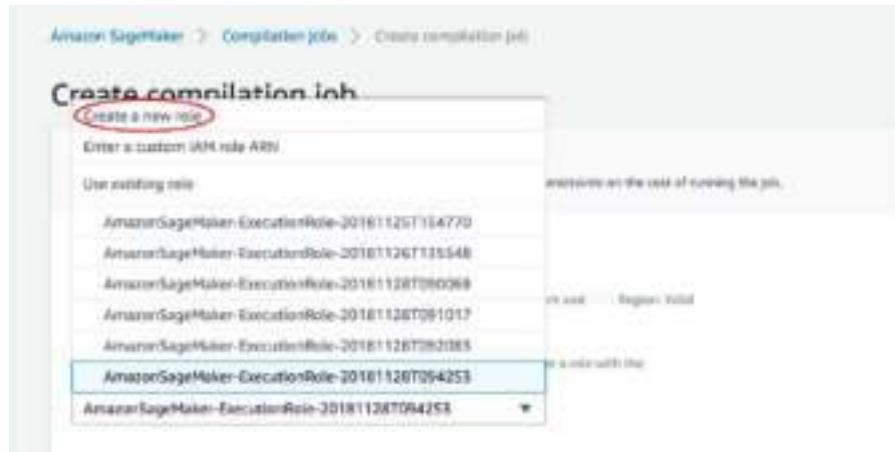

1. In the **Amazon SageMaker** console, choose **Compilation jobs**, and then choose **Create compilation job**.

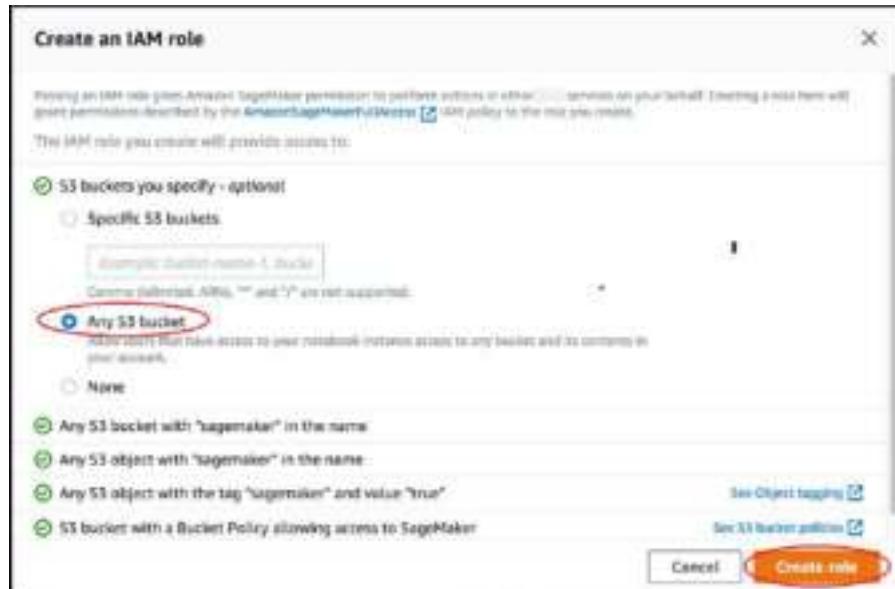

2. On the **Create compilation job** page, under **Job name**, enter a name. Then select an **IAM role**.

3. If you don't have an IAM role, choose **Create a new role**.

- On the **Create an IAM role** page, choose **Any S3 bucket**, and choose **Create role**.

- Non PyTorch Frameworks

Within the **Input configuration** section, enter the full path of the Amazon S3 bucket URI that contains your model artifacts in the **Location of model artifacts** input field. Your model artifacts must be in a compressed tarball file format (.tar.gz).

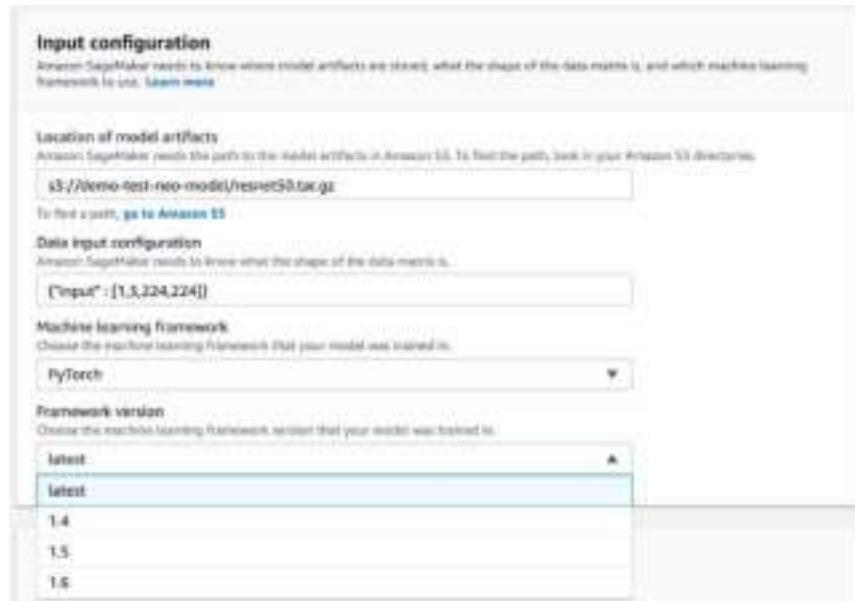

For the **Data input configuration** field, enter the JSON string that specifies the shape of the input data. For **Machine learning framework**, choose the framework of your choice.

To find the JSON string examples of input data shapes depending on frameworks, see [What input data shapes Neo expects](#).

#### PyTorch Framework

Similar instructions apply for compiling PyTorch models. However, if you trained with PyTorch and are trying to compile the model for `m1_*` (except `m1_inf`) target, you can optionally specify the version of PyTorch you used.

To find the JSON string examples of input data shapes depending on frameworks, see [What input data shapes Neo expects](#).

#### Note

When compiling for `m1_*` instances using PyTorch framework, use **Compiler options** field in **Output Configuration** to provide the correct data type (`dtype`) of the model's input. The default is set to "float32".

**Output configuration**  
Amazon SageMaker needs to know where to store the modules compiled with this job. [Learn more](#)

**Target device**  
Choose the target device or the machine learning instance that you want to run your model on after the compilation has completed.

**Target platform**  
Select the target platform that you want your model to run on, such as CPU, architecture, and accelerators.

**Target device**  
Amazon SageMaker needs to know where you intend to deploy your model to an Amazon SageMaker ML instance or to an AWS Greengrass device.

ml\_c5

**Compiler options - optional**  
Specify additional parameters for compiler options in JSON format:  
{"fileType": "TensorRT"}

**S3 Output location**  
Amazon SageMaker needs the path to the S3 bucket or folder where you want to store the compiled module.

s3://bucket-example/detect.tar.gz

To find a path, [go to Amazon S3](#).

**Encryption key - optional**  
Encrypt your data. Choose an existing KMS key or enter a key's ARN:

No Custom Encryption

### Warning

If you specify a Amazon S3 bucket URI path that leads to .pth file, you will receive the following error after starting compilation: **ClientError: InputConfiguration: Unable to untar input model. Please confirm the model is a tar.gz file**

6. Go to the **Output configuration** section. Choose where you want to deploy your model. You can deploy your model to a **Target device** or a **Target platform**. Target devices include cloud and edge devices. Target platforms refer to specific OS, architecture, and accelerators you want your model to run on.

For **S3 Output location**, enter the path to the S3 bucket where you want to store the model. You can optionally add compiler options in JSON format under the **Compiler options** section.

**Output configuration**  
Amazon SageMaker needs to know where to store the modules compiled with this job. [Learn more](#)

**Target device**  
Choose the target device or the machine learning instance that you want to run your model on after the compilation has completed.

**Target platform**  
Select the target platform that you want your model to run on, such as CPU, architecture, and accelerators.

**Target device**  
Amazon SageMaker needs to know where you intend to deploy your model to an Amazon SageMaker ML instance or to an AWS Greengrass device.

Select a target device

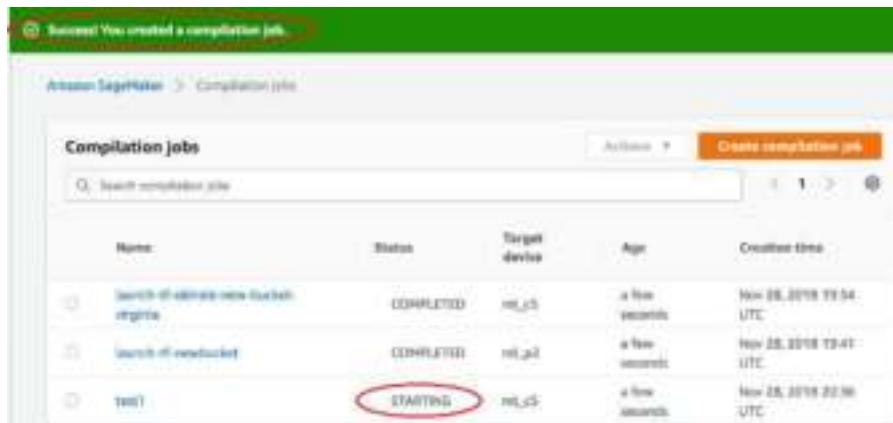

**Compiler options - optional**  
Specify additional parameters for compiler options in JSON format:  
{"fileType": "TensorRT"}

**S3 Output location**  
Amazon SageMaker needs the path to the S3 bucket or folder where you want to store the compiled module.

s3://bucket-example/detect.tar.gz

To find a path, [go to Amazon S3](#).

- Check the status of the compilation job when started. This status of the job can be found at the top of the **Compilation Job** page, as shown in the following screenshot. You can also check the status of it in the **Status** column.

- Check the status of the compilation job when completed. You can check the status in the **Status** column as shown in the following screenshot.

## Compile a Model (Amazon SageMaker SDK)

You can use the `compile_model` API in the [Amazon SageMaker SDK for Python](#) to compile a trained model and optimize it for specific target hardware. The API should be invoked on the estimator object used during model training.

### Note

You must set `MMS_DEFAULT_RESPONSE_TIMEOUT` environment variable to 500 when compiling the model with MXNet or PyTorch. The environment variable is not needed for TensorFlow.

The following is an example of how you can compile a model using the `trained_model_estimator` object:

```
# Replace the value of expected_trained_model_input below and
# specify the name & shape of the expected inputs for your trained model
# in json dictionary form
expected_trained_model_input = {'data':[1, 784]}

# Replace the example target_instance_family below to your preferred target_instance_family
compiled_model = trained_model_estimator.compile_model(target_instance_family='ml_c5',
    input_shape=expected_trained_model_input,
    output_path='insert s3 output path',
    env={'MMS_DEFAULT_RESPONSE_TIMEOUT': '500'})
```

The code compiles the model, saves the optimized model at `output_path`, and creates a SageMaker model that can be deployed to an endpoint. Sample notebooks of using the SDK for Python are provided in the [Neo Model Compilation Sample Notebooks](#) section.

## Cloud Instances

Amazon SageMaker Neo provides compilation support for popular machine learning frameworks such as TensorFlow, PyTorch, MXNet, and more. You can deploy your compiled model to cloud instances and Amazon Inferentia instances. For a full list of supported frameworks and instances types, see [Supported Instances Types and Frameworks](#).

You can compile your model in one of three ways: through the Amazon CLI, the SageMaker Console, or the SageMaker SDK for Python. See, [Use Neo to Compile a Model](#) for more information. Once compiled, your model artifacts are stored in the Amazon S3 bucket URI you specified during the compilation job. You can deploy your compiled model to cloud instances and Amazon Inferentia instances using the SageMaker SDK for Python, Amazon SDK for Python (Boto3), Amazon CLI, or the Amazon console.

If you deploy your model using Amazon CLI, the console, or Boto3, you must select a Docker image Amazon ECR URI for your primary container. See [Neo Inference Container Images](#) for a list of Amazon ECR URIs.

- [Inference Container Images \(p. 2060\)](#)

## Supported Instance Types and Frameworks

Amazon SageMaker Neo supports popular deep learning frameworks for both compilation and deployment. You can deploy your model to cloud instances, Amazon Inferentia instance types, or Amazon Elastic Inference accelerators.

The following describes frameworks SageMaker Neo supports and the target cloud instances you can compile and deploy to. For information on how to deploy your compiled model to a cloud or Inferentia instance, see [Deploy a Model with Cloud Instances](#). For information on how to deploy your compiled model with Elastic Inference accelerators, see [Use EI on Amazon SageMaker Hosted Endpoints \(p. 1884\)](#).

## Cloud Instances

SageMaker Neo supports the following deep learning frameworks for CPU and GPU cloud instances:

Framework	Framework Version	Model Version	Models	Model Formats (packaged in *.tar.gz)	Toolkits
MXNet	1.8.0	Supports 1.8.0 or earlier	Image Classification, Object Detection, Semantic Segmentation, Pose Estimation,	One symbol file (.json) and one parameter file (.params)	GluonCV v0.8.0

Framework	Framework Version	Model Version	Models	Model Formats (packaged in *.tar.gz)	Toolkits
			Activity Recognition		
ONNX	1.5.0	Supports 1.5.0 or earlier	Image Classification, SVM	One model file (.onnx)	
Keras	2.2.4	Supports 2.2.4 or earlier	Image Classification	One model definition file (.h5)	
PyTorch	1.6	Supports 1.4, 1.5, and 1.6	Image Classification	One model definition file (.pt or .pth) with input dtype of float32	
TensorFlow	1.15.0	Supports 1.15.0 or earlier	Image Classification	For saved models, one .pb or one .pbtxt file and a variables directory that contains variables  For frozen models, only one .pb or .pbtxt file	
TensorFlow-Lite	1.13.1	Supports 1.13.1 or earlier	Image Classification, Object Detection	One model definition flatbuffer file (.tflite)	
XGBoost	0.9	Supports 0.9 or earlier	Decision Trees	One XGBoost model file (.model) where the number of nodes in a tree is less than $2^{31}$	
DARKNET			Image Classification, Object Detection	One config (.cfg) file and one weights (.weights) file	

**Note**

“Model Version” is the version of the framework used to train and export the model.

## Instance Types

You can deploy your SageMaker compiled model to one of the cloud instances listed below:

Instance	Compute Type				
ml_c4	Standard				
ml_c5	Standard				
ml_m4	Standard				
ml_m5	Standard				
ml_p2	Accelerated computing				
ml_p3	Accelerated computing				
ml_g4dn	Accelerated computing				

For information on the available vCPU, memory, and price per hour for each instance type, see [Amazon SageMaker Pricing](#).

### Note

When compiling for ml\_\* instances using PyTorch framework, use **Compiler options** field in **Output Configuration** to provide the correct data type (dtype) of the model's input. The default is set to "float32".

## Amazon Inferentia

SageMaker Neo supports the following deep learning frameworks for Inferentia:

Framework	Framework Version	Model Version	Models	Model Formats (packaged in *.tar.gz)	Toolkits
MXNet	1.5.1	Supports 1.5.1 or earlier	Image Classification, Object Detection, Semantic Segmentation, Pose Estimation, Activity Recognition	One symbol file (.json) and one parameter file (.params)	GluonCV v0.8.0
PyTorch	1.5.1	Supports 1.5.1 or earlier	Image Classification	One model definition file (.pt or .pth) with input dtype of float32	

Framework	Framework Version	Model Version	Models	Model Formats (packaged in *.tar.gz)	Toolkits
TensorFlow	1.15.0	Supports 1.15.0 or earlier	Image Classification	For saved models, one .pb or one .pbtxt file and a variables directory that contains variables  For frozen models, only one .pb or .pbtxt file	

**Note**

"Model Version" is the version of the framework used to train and export the model.

You can deploy your SageMaker Neo-compiled model to Amazon Inferentia-based Amazon EC2 Inf1 instances. Amazon Inferentia is Amazon's first custom silicon chip designed to accelerate deep learning. Currently, you can use the `m1_inf1` instance to deploy your compiled models.

## Amazon Elastic Inference

SageMaker Neo supports the following deep learning frameworks for Elastic Inference:

Framework	Framework Version	Model Version	Models	Model Formats (packaged in *.tar.gz)
TensorFlow	2.3.2	Supports 2.3	Image Classification, Object Detection, Semantic Segmentation, Pose Estimation, Activity Recognition  For saved models, one .pb or one .pbtxt file and a variables directory that contains variables.  For frozen models, only one .pb or .pbtxt file.	

You can deploy your SageMaker Neo-compiled model to an Elastic Inference Accelerator. For more information, see [Use EI on Amazon SageMaker Hosted Endpoints \(p. 1884\)](#).

## Deploy a Model

To deploy an Amazon SageMaker Neo-compiled model to an HTTPS endpoint, you must configure and create the endpoint for the model using Amazon SageMaker hosting services. Currently, developers can use Amazon SageMaker APIs to deploy modules on to `ml.c5`, `ml.c4`, `ml.m5`, `ml.m4`, `ml.p3`, `ml.p2`, and `ml.inf1` instances.

For [Inf1 instances](#), models need to be compiled specifically for ml.inf1 instances. Models compiled for other instance types are not guaranteed to work with ml.inf1 instances.

For [Elastic Inference accelerators](#), models need to be compiled specifically for ml\_eia2 devices. For information on how to deploy your compiled model to an Elastic Inference accelerator, see [Use EI on Amazon SageMaker Hosted Endpoints \(p. 1884\)](#).

When you deploy a compiled model, you need to use the same instance for the target that you used for compilation. This creates a SageMaker endpoint that you can use to perform inferences. You can deploy a Neo-compiled model using any of the following: [Amazon SageMaker SDK for Python](#), [SDK for Python \(Boto3\)](#), [Amazon Command Line Interface](#), and the SageMaker console<https://console.amazonaws.cn/SageMaker>.

#### Note

For deploying a model using Amazon CLI, the console, or Boto3, see [Neo Inference Container Images](#) to select the inference image URI for your primary container.

#### Topics

- [Prerequisites \(p. 2040\)](#)
- [Deploy a Compiled Model Using SageMaker SDK \(p. 2046\)](#)
- [Deploy a Compiled Model Using Boto3 \(p. 2049\)](#)
- [Deploy a Compiled Model Using the Amazon CLI \(p. 2050\)](#)
- [Deploy a Compiled Model Using the Console \(p. 2052\)](#)

## Prerequisites

#### Note

Follow the instructions in this section if you compiled your model using Amazon SDK for Python (Boto3), Amazon CLI, or the SageMaker console.

To create a SageMaker Neo-compiled model, you need the following:

1. A Docker image Amazon ECR URI. You can select one that meets your needs from [this list](#).
2. An entry point script file:

a. **For PyTorch and MXNet models:**

*If you trained your model using SageMaker*, the training script must implement the functions described below. The training script serves as the entry point script during inference. In the example detailed in [MNIST Training, Compilation and Deployment with MXNet Module and SageMaker Neo](#), the training script (`mnist.py`) implements the required functions.

*If you did not train your model using SageMaker*, you need to provide an entry point script (`inference.py`) file that can be used at the time of inference. Based on the framework—MXNet or PyTorch—the inference script location must conform to the SageMaker Python SDK [Model Directory Structure for MxNet](#) or [Model Directory Structure for PyTorch](#).

When using Neo Inference Optimized Container images with **PyTorch** and **MXNet** on CPU and GPU instance types, the inference script must implement the following functions:

- `model_fn`: Loads the model.
- `input_fn`: Converts the incoming request payload into a numpy array.
- `predict_fn`: Performs the prediction.
- `output_fn`: Converts the prediction output into the response payload.
- Alternatively, you can define `transform_fn` to combine `input_fn`, `predict_fn`, and `output_fn`.

The following are examples of `inference.py` script within a directory named `code` (`code/inference.py`) for **PyTorch** and **MXNet (Gluon and Module)**. The examples first load the model and then serve it on image data on a GPU:

#### MXNet Module

```

import numpy as np
import json
import mxnet as mx
import neomx # noqa: F401
from collections import namedtuple

Batch = namedtuple('Batch', ['data'])

# Change the context to mx.cpu() if deploying to a CPU endpoint
ctx = mx.gpu()

def model_fn(model_dir):
    # The compiled model artifacts are saved with the prefix 'compiled'
    sym, arg_params, aux_params = mx.model.load_checkpoint('compiled', 0)
    mod = mx.mod.Module(symbol=sym, context=ctx, label_names=None)
    exe = mod.bind(for_training=False,
                    data_shapes=[('data', (1,3,224,224))],
                    label_shapes=mod._label_shapes)
    mod.set_params(arg_params, aux_params, allow_missing=True)

    # Run warm-up inference on empty data during model load (required for GPU)
    data = mx.nd.empty((1,3,224,224), ctx=ctx)
    mod.forward(Batch([data]))
    return mod

def transform_fn(mod, image, input_content_type, output_content_type):
    # pre-processing
    decoded = mx.image.imdecode(image)
    resized = mx.image.resize_short(decoded, 224)
    cropped, crop_info = mx.image.center_crop(resized, (224, 224))
    normalized = mx.image.color_normalize(cropped.astype(np.float32) / 255,
                                           mean=mx.nd.array([0.485, 0.456, 0.406]),
                                           std=mx.nd.array([0.229, 0.224, 0.225]))
    transposed = normalized.transpose((2, 0, 1))
    batchified = transposed.expand_dims(axis=0)
    casted = batchified.astype(dtype='float32')
    processed_input = casted.as_in_context(ctx)

    # prediction/inference
    mod.forward(Batch([processed_input]))

    # post-processing
    prob = mod.get_outputs()[0].asnumpy().tolist()
    prob_json = json.dumps(prob)
    return prob_json, output_content_type

```

#### MXNet Gluon

```

import numpy as np
import json
import mxnet as mx
import neomx # noqa: F401

# Change the context to mx.cpu() if deploying to a CPU endpoint

```

```

ctx = mx.gpu()

def model_fn(model_dir):
    # The compiled model artifacts are saved with the prefix 'compiled'
    block = mx.gluon.nn.SymbolBlock.imports('compiled-symbol.json',
    ['data'], 'compiled-0000.params', ctx=ctx)

    # Hybridize the model & pass required options for Neo: static_alloc=True &
    static_shape=True
    block.hybridize(static_alloc=True, static_shape=True)

    # Run warm-up inference on empty data during model load (required for GPU)
    data = mx.nd.empty((1,3,224,224), ctx=ctx)
    warm_up = block(data)
    return block

def input_fn(image, input_content_type):
    # pre-processing
    decoded = mx.image.imdecode(image)
    resized = mx.image.resize_short(decoded, 224)
    cropped, crop_info = mx.image.center_crop(resized, (224, 224))
    normalized = mx.image.color_normalize(cropped.astype(np.float32) / 255,
                                           mean=mx.nd.array([0.485, 0.456, 0.406]),
                                           std=mx.nd.array([0.229, 0.224, 0.225]))
    transposed = normalized.transpose((2, 0, 1))
    batchified = transposed.expand_dims(axis=0)
    casted = batchified.astype(dtype='float32')
    processed_input = casted.as_in_context(ctx)
    return processed_input

def predict_fn(processed_input_data, block):
    # prediction/inference
    prediction = block(processed_input_data)
    return prediction

def output_fn(prediction, output_content_type):
    # post-processing
    prob = prediction.numpy().tolist()
    prob_json = json.dumps(prob)
    return prob_json, output_content_type

```

### PyTorch 1.4 and Older

```

import os
import torch
import torch.nn.parallel
import torch.optim
import torch.utils.data
import torch.utils.data.distributed
import torchvision.transforms as transforms
from PIL import Image
import io
import json
import pickle

def model_fn(model_dir):
    """Load the model and return it.
    Providing this function is optional.
    There is a default model_fn available which will load the model
    compiled using SageMaker Neo. You can override it here.

```

```

Keyword arguments:
model_dir -- the directory path where the model artifacts are present
"""

# The compiled model is saved as "compiled.pt"
model_path = os.path.join(model_dir, 'compiled.pt')
with torch.neuro.config(model_dir=model_dir, neo_runtime=True):
    model = torch.jit.load(model_path)
    device = torch.device("cuda" if torch.cuda.is_available() else "cpu")
    model = model.to(device)

# We recommend that you run warm-up inference during model load
sample_input_path = os.path.join(model_dir, 'sample_input.pkl')
with open(sample_input_path, 'rb') as input_file:
    model_input = pickle.load(input_file)
if torch.is_tensor(model_input):
    model_input = model_input.to(device)
    model(model_input)
elif isinstance(model_input, tuple):
    model_input = (inp.to(device) for inp in model_input if
        torch.is_tensor(inp))
    model(*model_input)
else:
    print("Only supports a torch tensor or a tuple of torch tensors")
    return model

def transform_fn(model, request_body, request_content_type,
                response_content_type):
    """Run prediction and return the output.
    The function
    1. Pre-processes the input request
    2. Runs prediction
    3. Post-processes the prediction output.
    """
    # preprocess
    decoded = Image.open(io.BytesIO(request_body))
    preprocess = transforms.Compose([
        transforms.Resize(256),
        transforms.CenterCrop(224),
        transforms.ToTensor(),
        transforms.Normalize(
            mean=[0.485, 0.456, 0.406], std=[0.229, 0.224, 0.225]),
    ])
    normalized = preprocess(decoded)
    batchified = normalized.unsqueeze(0)
    # predict
    device = torch.device("cuda" if torch.cuda.is_available() else "cpu")
    batchified = batchified.to(device)
    output = model.forward(batchified)

    return json.dumps(output.cpu().numpy().tolist()), response_content_type

```

## PyTorch 1.5 and Newer

Use `neopytorch` to specify the file path of the model if you trained with PyTorch version 1.5 and newer.

```

import os
import torch
import neopytorch
import torch.nn.parallel

```

```

import torch.optim
import torch.utils.data
import torch.utils.data.distributed
import torchvision.transforms as transforms
from PIL import Image
import io
import json
import pickle

def model_fn(model_dir):
    """Load the model and return it.
    Providing this function is optional.
    There is a default model_fn available which will load the model
    compiled using SageMaker Neo. You can override it here.

    Keyword arguments:
    model_dir -- the directory path where the model artifacts are present
    """

    # The compiled model is saved as "compiled.pt"
    model_path = os.path.join(model_dir, 'compiled.pt')
    neopytorch.config(model_dir=model_dir, neo_runtime=True)
    device = torch.device("cuda" if torch.cuda.is_available() else "cpu")
    model = torch.jit.load(model_path, map_location=device)
    model = model.to(device)

    # We recommend that you run warm-up inference during model load
    sample_input_path = os.path.join(model_dir, 'sample_input.pkl')
    with open(sample_input_path, 'rb') as input_file:
        model_input = pickle.load(input_file)
    if torch.is_tensor(model_input):
        model_input = model_input.to(device)
        model(model_input)
    elif isinstance(model_input, tuple):
        model_input = (inp.to(device)
                      for inp in model_input if torch.is_tensor(inp))
        model(*model_input)
    else:
        print("Only supports a torch tensor or a tuple of torch tensors")
    return model

def transform_fn(model, request_body, request_content_type,
                response_content_type):
    """Run prediction and return the output.
    The function
    1. Pre-processes the input request
    2. Runs prediction
    3. Post-processes the prediction output.
    """
    # preprocess
    decoded = Image.open(io.BytesIO(request_body))
    preprocess = transforms.Compose([
        transforms.Resize(256),
        transforms.CenterCrop(224),
        transforms.ToTensor(),
        transforms.Normalize(
            mean=[0.485, 0.456, 0.406], std=[0.229, 0.224, 0.225]),
    ])
    normalized = preprocess(decoded)
    batchified = normalized.unsqueeze(0)

    # predict

```

```
device = torch.device("cuda" if torch.cuda.is_available() else "cpu")
batchified = batchified.to(device)
output = model.forward(batchified)
return json.dumps(output.cpu().numpy().tolist()), response_content_type
```

b. **For inf1 instances or onnx, xgboost, keras container images**

For all other Neo Inference-optimized container images, or inferentia instance types, the entry point script must implement the following functions for Neo Deep Learning Runtime:

- **neo\_preprocess**: Converts the incoming request payload into a numpy array.
- **neo\_postprocess**: Converts the prediction output from Neo Deep Learning Runtime into the response body.

**Note**

The preceding two functions do not use any of the functionalities of MXNet, PyTorch, or TensorFlow.

For examples of how to use these functions, see [Neo Model Compilation Sample Notebooks](#).

c. **For TensorFlow models**

If your model requires custom pre- and post-processing logic before data is sent to the model, then you must specify an entry point script `inference.py` file that can be used at the time of inference. The script should implement either a pair of `input_handler` and `output_handler` functions or a single handler function.

**Note**

Note that if handler function is implemented, `input_handler` and `output_handler` are ignored.

The following is a code example of `inference.py` script that you can put together with the compile model to perform custom pre- and post-processing on an image classification model. The SageMaker client sends the image file as an `application/x-image` content type to the `input_handler` function, where it is converted to JSON. The converted image file is then sent to the [Tensorflow Model Server \(TFX\)](#) using the REST API.

```
import json
import numpy as np
import json
import io
from PIL import Image

def input_handler(data, context):
    """ Pre-process request input before it is sent to TensorFlow Serving REST API

    Args:
        data (obj): the request data, in format of dict or string
        context (Context): an object containing request and configuration details

    Returns:
        (dict): a JSON-serializable dict that contains request body and headers
    """
    f = data.read()
    f = io.BytesIO(f)
    image = Image.open(f).convert('RGB')
    batch_size = 1
    image = np.asarray(image.resize((512, 512)))
    image = np.concatenate([image[np.newaxis, :, :] * batch_size]
```

```

body = json.dumps({"signature_name": "serving_default", "instances":
    image.tolist()})
return body

def output_handler(data, context):
    """Post-process TensorFlow Serving output before it is returned to the client.

    Args:
        data (obj): the TensorFlow serving response
        context (Context): an object containing request and configuration details

    Returns:
        (bytes, string): data to return to client, response content type
    """
    if data.status_code != 200:
        raise ValueError(data.content.decode('utf-8'))

    response_content_type = context.accept_header
    prediction = data.content
    return prediction, response_content_type

```

If there is no custom pre- or post-processing, the SageMaker client converts the file `image` to JSON in a similar way before sending it over to the SageMaker endpoint.

For more information, see the [Deploying to TensorFlow Serving Endpoints in the SageMaker Python SDK](#).

3. The Amazon S3 bucket URI that contains the compiled model artifacts.

## Deploy a Compiled Model Using SageMaker SDK

You must satisfy the [prerequisites](#) section if the model was compiled using Amazon SDK for Python (Boto3), Amazon CLI, or the Amazon SageMaker console. Follow one of the following use cases to deploy a model compiled with SageMaker Neo based on how you compiled your model.

### Topics

- [If you compiled your model using the SageMaker SDK \(p. 2046\)](#)
- [If you compiled your model using MXNet or PyTorch \(p. 2046\)](#)
- [If you compiled your model using Boto3, SageMaker console, or the CLI for TensorFlow \(p. 2048\)](#)

### If you compiled your model using the SageMaker SDK

The `sagemaker.Model` object handle for the compiled model supplies the `deploy()` function, which enables you to create an endpoint to serve inference requests. The function lets you set the number and type of instances that are used for the endpoint. You must choose an instance for which you have compiled your model. For example, in the job compiled in [Compile a Model \(Amazon SageMaker SDK\)](#) section, this is `m1_c5`.

```

predictor = compiled_model.deploy(initial_instance_count = 1, instance_type =
    'ml.c5.4xlarge')

# Print the name of newly created endpoint
print(predictor.endpoint_name)

```

### If you compiled your model using MXNet or PyTorch

Create the SageMaker model and deploy it using the `deploy()` API under the framework-specific Model APIs. For MXNet, it is [MXNetModel](#) and for PyTorch, it is [PyTorchModel](#). When you are creating and deploying an SageMaker model, you must set `MMS_DEFAULT_RESPONSE_TIMEOUT` environment variable

to 500 and specify the `entry_point` parameter as the inference script (`inference.py`) and the `source_dir` parameter as the directory location (code) of the inference script. To prepare the inference script (`inference.py`) follow the Prerequisites step.

The following example shows how to use these functions to deploy a compiled model using the SageMaker SDK for Python:

#### MXNet

```
from sagemaker.mxnet import MXNetModel

# Create SageMaker model and deploy an endpoint
sm_mxnet_compiled_model = MXNetModel(
    model_data='insert S3 path of compiled MXNet model archive',
    role='AmazonSageMaker-ExecutionRole',
    entry_point='inference.py',
    source_dir='code',
    framework_version='1.8.0',
    py_version='py3',
    image_uri='insert appropriate ECR Image URI for MXNet',
    env={'MMS_DEFAULT_RESPONSE_TIMEOUT': '500'},
)

# Replace the example instance_type below to your preferred instance_type
predictor = sm_mxnet_compiled_model.deploy(initial_instance_count = 1, instance_type =
'ml.p3.2xlarge')

# Print the name of newly created endpoint
print(predictor.endpoint_name)
```

#### PyTorch 1.4 and Older

```
from sagemaker.pytorch import PyTorchModel

# Create SageMaker model and deploy an endpoint
sm_pytorch_compiled_model = PyTorchModel(
    model_data='insert S3 path of compiled PyTorch model archive',
    role='AmazonSageMaker-ExecutionRole',
    entry_point='inference.py',
    source_dir='code',
    framework_version='1.4.0',
    py_version='py3',
    image_uri='insert appropriate ECR Image URI for PyTorch',
    env={'MMS_DEFAULT_RESPONSE_TIMEOUT': '500'},
)

# Replace the example instance_type below to your preferred instance_type
predictor = sm_pytorch_compiled_model.deploy(initial_instance_count = 1, instance_type =
'ml.p3.2xlarge')

# Print the name of newly created endpoint
print(predictor.endpoint_name)
```

#### PyTorch 1.5 and Newer

```
from sagemaker.pytorch import PyTorchModel

# Create SageMaker model and deploy an endpoint
sm_pytorch_compiled_model = PyTorchModel(
    model_data='insert S3 path of compiled PyTorch model archive',
    role='AmazonSageMaker-ExecutionRole',
    entry_point='inference.py',
    source_dir='code',
```

```

        framework_version='1.5',
        py_version='py3',
        image_uri='insert appropriate ECR Image URI for PyTorch',
    )

# Replace the example instance_type below to your preferred instance_type
predictor = sm_pytorch_compiled_model.deploy(initial_instance_count = 1, instance_type
= 'ml.p3.2xlarge')

# Print the name of newly created endpoint
print(predictor.endpoint_name)

```

**Note**

The `AmazonSageMakerFullAccess` and `AmazonS3ReadOnlyAccess` policies must be attached to the `AmazonSageMaker-ExecutionRole` IAM role.

**If you compiled your model using Boto3, SageMaker console, or the CLI for TensorFlow**

Construct a `TensorFlowModel` object, then call `deploy`:

```

role='AmazonSageMaker-ExecutionRole'
model_path='S3 path for model file'
framework_image='inference container arn'
tf_model = TensorFlowModel(model_data=model_path,
                           framework_version='1.15.3',
                           role=role,
                           image_uri=framework_image)
instance_type='ml.c5.xlarge'
predictor = tf_model.deploy(instance_type=instance_type,
                           initial_instance_count=1)

```

See [Deploying directly from model artifacts](#) for more information.

You can select a Docker image Amazon ECR URI that meets your needs from [this list](#).

For more information on how to construct a `TensorFlowModel` object, see the [SageMaker SDK](#).

**Note**

Your first inference request might have high latency if you deploy your model on a GPU. This is because an optimized compute kernel is made on the first inference request. We recommend that you make a warm-up file of inference requests and store that alongside your model file before sending it off to a TFX. This is known as "warming up" the model.

The following code snippet demonstrates how to produce the warm-up file for image classification example in the [prerequisites](#) section:

```

import tensorflow as tf
from tensorflow_serving.apis import classification_pb2
from tensorflow_serving.apis import inference_pb2
from tensorflow_serving.apis import model_pb2
from tensorflow_serving.apis import predict_pb2
from tensorflow_serving.apis import prediction_log_pb2
from tensorflow_serving.apis import regression_pb2
import numpy as np

with tf.python_io.TFRecordWriter("tf_serving_warmup_requests") as writer:
    img = np.random.uniform(0, 1, size=[224, 224, 3]).astype(np.float32)
    img = np.expand_dims(img, axis=0)
    test_data = np.repeat(img, 1, axis=0)
    request = predict_pb2.PredictRequest()
    request.model_spec.name = 'compiled_models'

```

```
request.model_spec.signature_name = 'serving_default'
request.inputs['Placeholder:0'].CopyFrom(tf.compat.v1.make_tensor_proto(test_data,
shape=test_data.shape, dtype=tf.float32))
log = prediction_log_pb2.PredictionLog(
predict_log=prediction_log_pb2.PredictLog(request=request))
writer.write(log.SerializeToString())
```

For more information on how to “warm up” your model, see the [TensorFlow TFX page](#).

## Deploy a Compiled Model Using Boto3

You must satisfy the [prerequisites](#) section if the model was compiled using Amazon SDK for Python (Boto3), Amazon CLI, or the Amazon SageMaker console. Follow the steps below to create and deploy a SageMaker Neo-compiled model using [Amazon Web Services SDK for Python \(Boto3\)](#).

### Topics

- [Deploy the Model \(p. 2049\)](#)

### Deploy the Model

After you have satisfied the [prerequisites](#), use the `create_model`, `create_endpoint_config`, and `create_endpoint` APIs.

The following example shows how to use these APIs to deploy a model compiled with Neo:

```
import boto3
client = boto3.client('sagemaker')

# create sagemaker model
create_model_api_response = client.create_model(
    ModelName='my-sagemaker-model',
    PrimaryContainer={
        'Image': <insert the ECR Image URI>,
        'ModelDataUrl': 's3://path/to/model/artifact/
model.tar.gz',
        'Environment': {}
    },
    ExecutionRoleArn='ARN for AmazonSageMaker-
ExecutionRole'
)

print ("create_model API response", create_model_api_response)

# create sagemaker endpoint config
create_endpoint_config_api_response = client.create_endpoint_config(
    EndpointConfigName='sagemaker-neomxnet-
endpoint-configuration',
    ProductionVariants=[
        {
            'VariantName': <provide your variant
name>,
            'ModelName': 'my-sagemaker-model',
            'InitialInstanceCount': 1,
            'InstanceType': <provide your instance
type here>
        },
    ]
)

print ("create_endpoint_config API response", create_endpoint_config_api_response)

# create sagemaker endpoint
```

```
create_endpoint_api_response = client.create_endpoint(
    EndpointName='provide your endpoint name',
    EndpointConfigName=<insert your endpoint config name>,
)
print ("create_endpoint API response", create_endpoint_api_response)
```

### Note

The `AmazonSageMakerFullAccess` and `AmazonS3ReadOnlyAccess` policies must be attached to the `AmazonSageMaker-ExecutionRole` IAM role.

For full syntax of `create_model`, `create_endpoint_config`, and `create_endpoint` APIs, see [create\\_model](#), [create\\_endpoint\\_config](#), and [create\\_endpoint](#), respectively.

If you did not train your model using SageMaker, specify the following environment variables:

MXNet and PyTorch

```
"Environment": {
    "SAGEMAKER_PROGRAM": "inference.py",
    "SAGEMAKER_SUBMIT_DIRECTORY": "/opt/ml/model/code",
    "SAGEMAKER_CONTAINER_LOG_LEVEL": "20",
    "SAGEMAKER_REGION": "insert your region",
    "MMS_DEFAULT_RESPONSE_TIMEOUT": "500"
}
```

TensorFlow

```
"Environment": {
    "SAGEMAKER_PROGRAM": "inference.py",
    "SAGEMAKER_SUBMIT_DIRECTORY": "/opt/ml/model/code",
    "SAGEMAKER_CONTAINER_LOG_LEVEL": "20",
    "SAGEMAKER_REGION": "insert your region"
}
```

If you trained your model using SageMaker, specify the environment variable `SAGEMAKER_SUBMIT_DIRECTORY` as the full Amazon S3 bucket URI that contains the training script.

## Deploy a Compiled Model Using the Amazon CLI

You must satisfy the [prerequisites](#) section if the model was compiled using Amazon SDK for Python (Boto3), Amazon CLI, or the Amazon SageMaker console. Follow the steps below to create and deploy a SageMaker Neo-compiled model using the [Amazon CLI](#).

### Topics

- [Deploy the Model \(p. 2050\)](#)

### Deploy the Model

After you have satisfied the [prerequisites](#), use the `create-model`, `create-endpoint-config`, and `create-endpoint` Amazon CLI commands. The following steps explain how to use these commands to deploy a model compiled with Neo:

### Create a Model

From [Neo Inference Container Images](#), select the inference image URI and then use `create-model` API to create a SageMaker model. You can do this with two steps:

1. Create a `create_model.json` file. Within the file, specify the name of the model, the image URI, the path to the `model.tar.gz` file in your Amazon S3 bucket, and your SageMaker execution role:

```
{
  "ModelName": "insert model name",
  "PrimaryContainer": {
    "Image": "insert the ECR Image URI",
    "ModelDataURL": "insert S3 archive URL",
    "Environment": {"See details below"}
  },
  "ExecutionRoleArn": "ARN for AmazonSageMaker-ExecutionRole"
}
```

If you trained your model using SageMaker, specify the following environment variable:

```
"Environment": {
  "SAGEMAKER_SUBMIT_DIRECTORY" : "[Full S3 path for *.tar.gz file containing the training script]"
}
```

If you did not train your model using SageMaker, specify the following environment variables:  
MXNet and PyTorch

```
"Environment": {
  "SAGEMAKER_PROGRAM": "inference.py",
  "SAGEMAKER_SUBMIT_DIRECTORY": "/opt/ml/model/code",
  "SAGEMAKER_CONTAINER_LOG_LEVEL": "20",
  "SAGEMAKER_REGION": "insert your region",
  "MMS_DEFAULT_RESPONSE_TIMEOUT": "500"
}
```

TensorFlow

```
"Environment": {
  "SAGEMAKER_PROGRAM": "inference.py",
  "SAGEMAKER_SUBMIT_DIRECTORY": "/opt/ml/model/code",
  "SAGEMAKER_CONTAINER_LOG_LEVEL": "20",
  "SAGEMAKER_REGION": "insert your region"
}
```

#### Note

The `AmazonSageMakerFullAccess` and `AmazonS3ReadOnlyAccess` policies must be attached to the `AmazonSageMaker-ExecutionRole` IAM role.

2. Run the following command:

```
aws sagemaker create-model --cli-input-json file://create_model.json
```

For the full syntax of the `create-model` API, see [create-model](#).

## Create an Endpoint Configuration

After creating a SageMaker model, create the endpoint configuration using the `create-endpoint-config` API. To do this, create a JSON file with your endpoint configuration specifications. For example, you can use the following code template and save it as `create_config.json`:

```
{
```

```
"EndpointConfigName": "<provide your endpoint config name>",
"ProductionVariants": [
    {
        "VariantName": "<provide your variant name>",
        "ModelName": "my-sagemaker-model",
        "InitialInstanceCount": 1,
        "InstanceType": "<provide your instance type here>",
        "InitialVariantWeight": 1.0
    }
]
```

Now run the following Amazon CLI command to create your endpoint configuration:

```
aws sagemaker create-endpoint-config --cli-input-json file://create_config.json
```

For the full syntax of the `create-endpoint-config` API, see [create-endpoint-config](#).

### Create an Endpoint

After you have created your endpoint configuration, create an endpoint using the `create-endpoint` API:

```
aws sagemaker create-endpoint --endpoint-name '<provide your endpoint name>' --endpoint-
config-name '<insert your endpoint config name>'
```

For the full syntax of the `create-endpoint` API, see [create-endpoint](#).

### Deploy a Compiled Model Using the Console

You must satisfy the [prerequisites](#) section if the model was compiled using Amazon SDK for Python (Boto3), the Amazon CLI, or the Amazon SageMaker console. Follow the steps below to create and deploy a SageMaker Neo-compiled model using the SageMaker console<https://console.amazonaws.cn/SageMaker>.

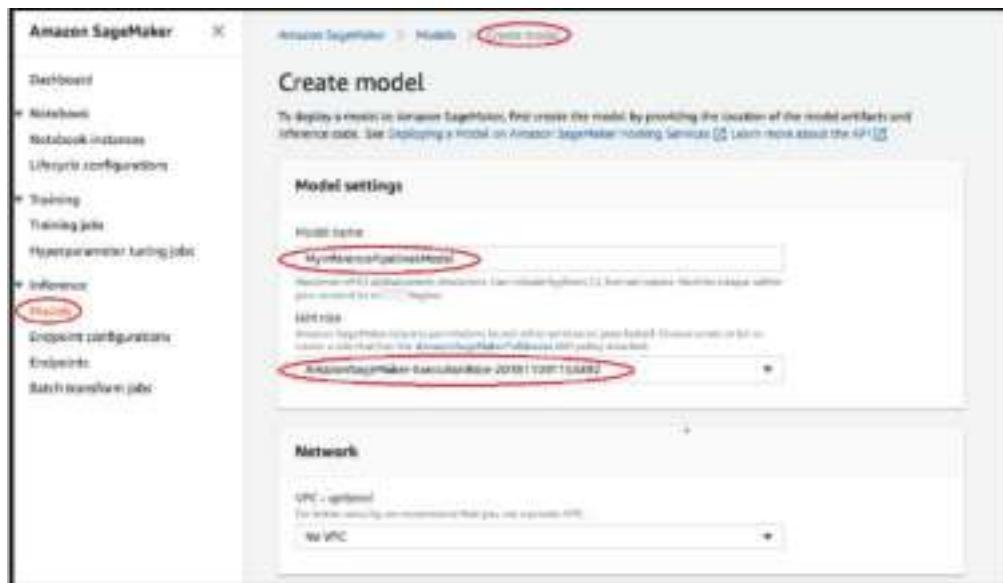

#### Topics

- [Deploy the Model \(p. 2052\)](#)

### Deploy the Model

After you have satisfied the [prerequisites](#), use the following steps to deploy a model compiled with Neo:

1. Choose **Models**, and then choose **Create models** from the **Inference** group. On the **Create model** page, complete the **Model name**, **IAM role**, and **VPC** fields (optional), if needed.

2. To add information about the container used to deploy your model, choose **Add container container**, then choose **Next**. Complete the **Container input options**, **Location of inference code image**, and **Location of model artifacts**, and optionally, **Container host name** and **Environmental variables** fields.

Key	Value	<b>Remove</b>
key1	value1	<b>Remove</b>
key2	value2	<b>Remove</b>

[Add environment variable](#)

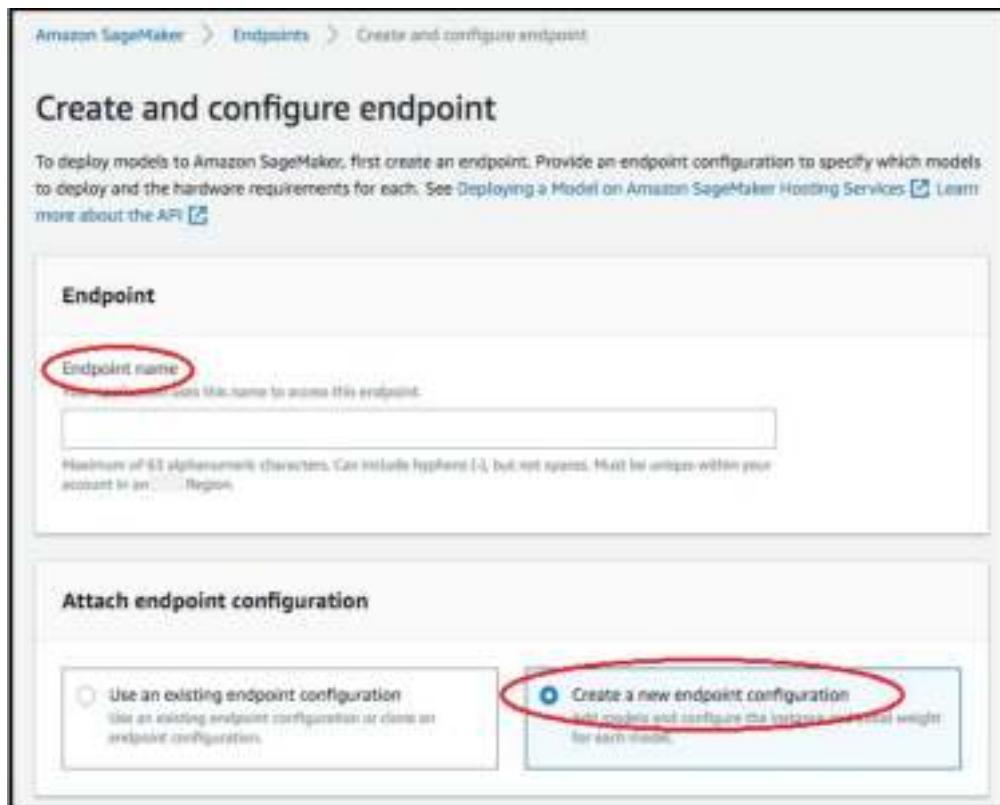

3. To deploy Neo-compiled models, choose the following:
  - **Container input options:** Choose **Provide model artifacts and inference image**.
  - **Location of inference code image:** Choose the inference image URI from [Neo Inference Container Images](#), depending on the Amazon Region and kind of application.
  - **Location of model artifact:** Enter the Amazon S3 bucket URI of the compiled model artifact generated by the Neo compilation API.
  - **Environment variables:**
    - Leave this field blank for **SageMaker XGBoost**.
    - If you trained your model using SageMaker, specify the environment variable `SAGEMAKER_SUBMIT_DIRECTORY` as the Amazon S3 bucket URI that contains the training script.
    - If you did not train your model using SageMaker, specify the following environment variables:

Key	Values for MXNet and PyTorch	Values TensorFlow
<code>SAGEMAKER_PROGRAM</code>	<code>inference.py</code>	<code>inference.py</code>
<code>SAGEMAKER_SUBMIT_DIRECTORY</code>	<code>/opt/ml/model/code</code>	<code>/opt/ml/model/code</code>
<code>SAGEMAKER_CONTAINER_LOG_LEVEL</code>	20	20
<code>SAGEMAKER_REGION</code>	<your region>	<your region>
<code>MMS_DEFAULT_RESPONSE_TIMEOUT</code>		Leave this field blank for TF

4. Confirm that the information for the containers is accurate, and then choose **Create model**. On the [Create model landing page](#), choose **Create endpoint**.

5. In [Create and configure endpoint](#) diagram, specify the **Endpoint name**. For **Attach endpoint configuration**, choose **Create a new endpoint configuration**.

6. In **New endpoint configuration** page, specify the **Endpoint configuration name**.

New endpoint configuration

To deploy models to Amazon SageMaker, first create an endpoint configuration. In the configuration, specify which models to deploy, and the relative traffic weighting and hardware requirements for each.

Endpoint configuration name

Maximum of 63 alphanumeric characters. Can include hyphens (-), but not spaces. Must be unique within your account in all Regions.

Encryption key - optional

Encrypt your data. Choose an existing AWS key or enter a key's ARN.

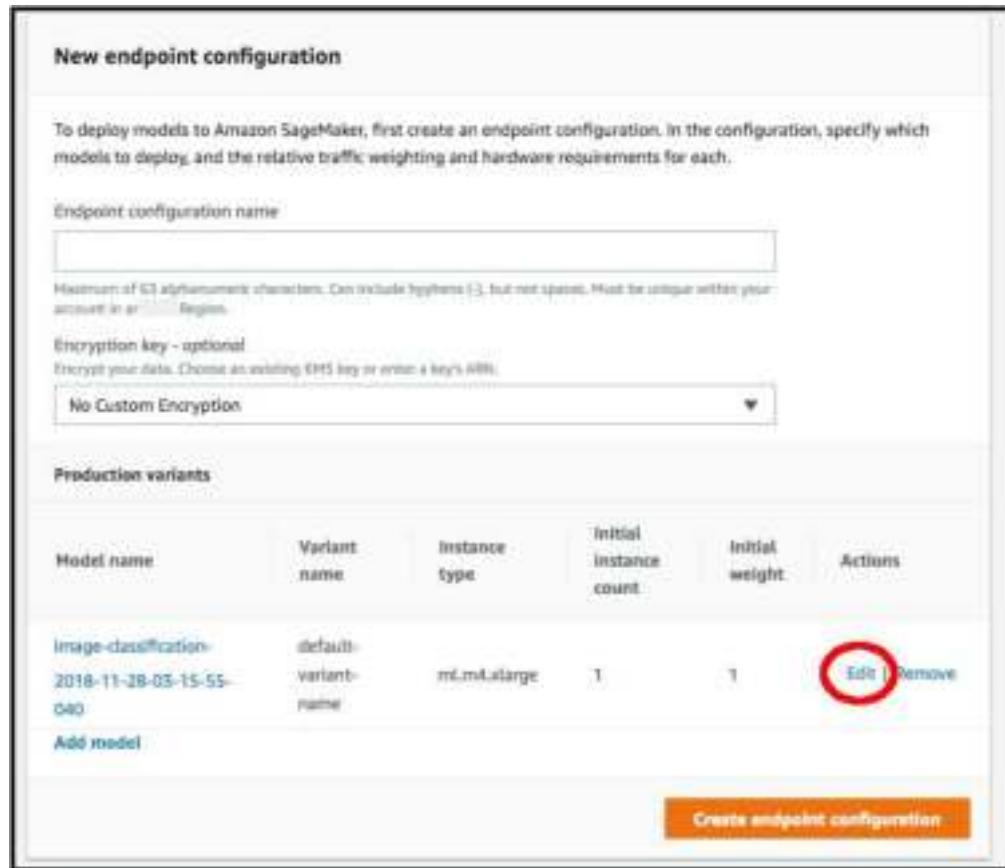

No Custom Encryption

Production variants

Model name	Variant name	Instance type	Initial instance count	Initial weight	Actions
image-classification-2018-11-28-03-15-55-040	default-variant-Name	ml.m4.xlarge	1	1	<a href="#">Edit   Remove</a>

Add model

Create endpoint configuration

7. Choose **Edit** next to the name of the model and specify the correct **Instance type** on the **Edit Production Variant** page. It is imperative that the **Instance type** value match the one specified in your compilation job.

**Edit Production Variant**

Model name: image-classification-2018-11-28-03-15-55-040

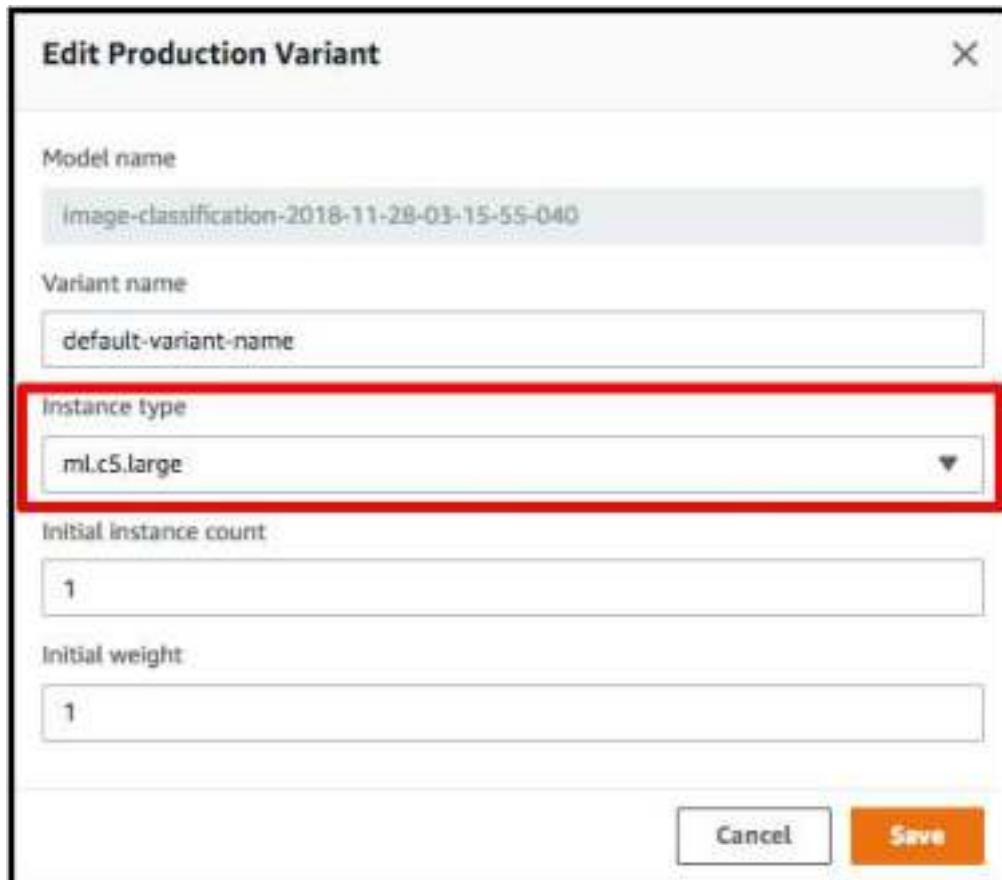

Variant name: default-variant-name

Instance type: ml.c5.large

Initial instance count: 1

Initial weight: 1

**Cancel** **Save**

8. Choose **Save**.
9. On the **New endpoint configuration** page, choose **Create endpoint configuration**, and then choose **Create endpoint**.

## Request Inferences from a Deployed Service

If you have followed instructions in [Deploy a Model \(p. 2039\)](#), you should have a SageMaker endpoint set up and running. Regardless of how you deployed your Neo-compiled model, there are three ways you can submit inference requests:

### Topics

- [Request Inferences from a Deployed Service \(Amazon SageMaker SDK\) \(p. 2057\)](#)
- [Request Inferences from a Deployed Service \(Boto3\) \(p. 2059\)](#)
- [Request Inferences from a Deployed Service \(Amazon CLI\) \(p. 2060\)](#)

### Request Inferences from a Deployed Service (Amazon SageMaker SDK)

Use the following the code examples to request inferences from your deployed service based on the framework you used to train your model. The code examples for the different frameworks are similar. The main difference is that TensorFlow requires `application/json` as the content type.

## PyTorch and MXNet

If you are using **PyTorch v1.4 or later** or **MXNet 1.7.0 or later** and you have an Amazon SageMaker endpoint InService, you can make inference requests using the `predictor` package of the SageMaker SDK for Python.

### Note

The API varies based on the SageMaker SDK for Python version:

- For version 1.x, use the `RealTimePredictor` and `Predict` API.
- For version 2.x, use the `Predictor` and the `Predict` API.

The following code example shows how to use these APIs to send an image for inference:

### SageMaker Python SDK v1.x

```
from sagemaker.predictor import RealTimePredictor
endpoint = 'insert name of your endpoint here'

# Read image into memory
payload = None
with open("image.jpg", 'rb') as f:
    payload = f.read()

predictor = RealTimePredictor(endpoint=endpoint, content_type='application/x-image')
inference_response = predictor.predict(data=payload)
print (inference_response)
```

### SageMaker Python SDK v2.x

```
from sagemaker.predictor import Predictor
endpoint = 'insert name of your endpoint here'

# Read image into memory
payload = None
with open("image.jpg", 'rb') as f:
    payload = f.read()

predictor = Predictor(endpoint)
inference_response = predictor.predict(data=payload)
print (inference_response)
```

## TensorFlow

The following code example shows how to use the SageMaker Python SDK API to send an image for inference:

```
from sagemaker.predictor import Predictor
from PIL import Image
import numpy as np
import json

endpoint = 'insert the name of your endpoint here'

# Read image into memory
image = Image.open(input_file)
batch_size = 1
image = np.asarray(image.resize((224, 224)))
```

```

image = image / 128 - 1
image = np.concatenate([image[np.newaxis, :, :]] * batch_size)
body = json.dumps({"instances": image.tolist()})

predictor = Predictor(endpoint)
inference_response = predictor.predict(data=body)
print(inference_response)

```

## Request Inferences from a Deployed Service (Boto3)

You can submit inference requests using SageMaker SDK for Python (Boto3) client and [invoke\\_endpoint\(\)](#) API once you have an SageMaker endpoint InService. The following code example shows how to send an image for inference:

PyTorch and MXNet

```

import boto3

import json

endpoint = 'insert name of your endpoint here'

runtime = boto3.Session().client('sagemaker-runtime')

# Read image into memory
with open(image, 'rb') as f:
    payload = f.read()
# Send image via InvokeEndpoint API
response = runtime.invoke_endpoint(EndpointName=endpoint, ContentType='application/x-
image', Body=payload)

# Unpack response
result = json.loads(response['Body'].read().decode())

```

TensorFlow

For TensorFlow submit an input with application/json for the content type.

```

from PIL import Image
import numpy as np
import json
import boto3

client = boto3.client('sagemaker-runtime')
input_file = 'path/to/image'
image = Image.open(input_file)
batch_size = 1
image = np.asarray(image.resize((224, 224)))
image = image / 128 - 1
image = np.concatenate([image[np.newaxis, :, :]] * batch_size)
body = json.dumps({"instances": image.tolist()})
ioc_predictor_endpoint_name = 'insert name of your endpoint here'
content_type = 'application/json'
ioc_response = client.invoke_endpoint(
    EndpointName=ioc_predictor_endpoint_name,
    Body=body,
    ContentType=content_type
)

```

XGBoost

For an XGBoost application, you should submit a CSV text instead:

```
import boto3
import json

endpoint = 'insert your endpoint name here'

runtime = boto3.Session().client('sagemaker-runtime')

csv_text = '1,-1.0,1.0,1.5,2.6'
# Send CSV text via InvokeEndpoint API
response = runtime.invoke_endpoint(EndpointName=endpoint, ContentType='text/csv',
    Body=csv_text)
# Unpack response
result = json.loads(response['Body'].read().decode())
```

Note that BYOM allows for a custom content type. For more information, see [runtime\\_InvokeEndpoint](#).

## Request Inferences from a Deployed Service (Amazon CLI)

Inference requests can be made with the `sagemaker-runtime invoke-endpoint` once you have an Amazon SageMaker endpoint InService. You can make inference requests with the Amazon Command Line Interface (Amazon CLI). The following example shows how to send an image for inference:

```
aws sagemaker-runtime invoke-endpoint --endpoint-name 'insert name of your endpoint here'
--body fileb://image.jpg --content-type=application/x-image output_file.txt
```

An `output_file.txt` with information about your inference requests is made if the inference was successful.

For TensorFlow submit an input with `application/json` as the content type.

```
aws sagemaker-runtime invoke-endpoint --endpoint-name 'insert name of your endpoint here'
--body fileb://input.json --content-type=application/json output_file.txt
```

## Inference Container Images

Based on your use case, replace the highlighted portion in the inference image URI template provided below with appropriate values.

### Amazon SageMaker XGBoost

```
aws_account_id.dkr.ecr.aws_region.amazonaws.com/xgboost-neo:latest
```

Replace `aws_account_id` from the table at the end of this page based on the `aws_region` you used.

### TensorFlow

CPU or GPU instance types

```
aws_account_id.dkr.ecr.aws_region.amazonaws.com/sagemaker-inference-
tensorflow:fx_version-instance_type-py3
```

Replace `aws_account_id` from the table at the end of this page based on the `aws_region` you used.

Replace `fx_version` with 1.15.3.

Replace `instance_type` with either cpu or gpu.

Inferentia instance types

```
aws_account_id.dkr.ecr.aws_region.amazonaws.com/sagemaker-neo-
tensorflow:fx_version-instance_type-py3
```

Replace `aws_account_id` from the table at the end of this page based on the `aws_region` you used. Note that for instance type inf only us-east-1 and us-west-2 are supported.

Replace `fx_version` with 1.15.0

Replace `instance_type` with inf.

## MXNet

CPU or GPU instance types

```
aws_account_id.dkr.ecr.aws_region.amazonaws.com/sagemaker-inference-
mxnet:fx_version-instance_type-py3
```

Replace `aws_account_id` from the table at the end of this page based on the `aws_region` you used.

Replace `fx_version` with 1.8.0.

Replace `instance_type` with either cpu or gpu.

Inferentia instance types

```
aws_account_id.dkr.ecr.aws_region.amazonaws.com/sagemaker-neo-
mxnet:fx_version-instance_type-py3
```

Replace `aws_region` with either us-east-1 or us-west-2.

Replace `aws_account_id` from the table at the end of this page based on the `aws_region` you used.

Replace `fx_version` with 1.5.1.

Replace `instance_type` with inf.

## PyTorch

CPU or GPU instance types

```
aws_account_id.dkr.ecr.aws_region.amazonaws.com/sagemaker-inference-
pytorch:fx_version-instance_type-py3
```

Replace `aws_account_id` from the table at the end of this page based on the `aws_region` you used.

Replace `fx_version` with 1.4, 1.5, or 1.6.

Replace `instance_type` with either cpu or gpu.

Inferentia instance types

```
aws_account_id.dkr.ecr.aws_region.amazonaws.com/sagemaker-neo-
pytorch:fx_version-instance_type-py3
```

Replace `aws_region` with either `us-east-1` or `us-west-2`.

Replace `aws_account_id` from the table at the end of this page based on the `aws_region` you used.

Replace `fx_version` with `1.5.1`.

Replace `instance_type` with `inf`.

## Darknet

`aws_account_id.dkr.ecr.aws_region.amazonaws.com/sagemaker-neo-darknet:instance-type`

Replace `aws_account_id` from the table at the end of this page based on the `aws_region` you used.

Replace `instance-type` with either `cpu` or `gpu`.

The following table maps `aws_account_id` with `aws_region`. Use this table to find the correct inference image URI you need for your application.

<code>aws_account_id</code>	<code>aws_region</code>
785573368785	us-east-1
007439368137	us-east-2
710691900526	us-west-1
301217895009	us-west-2
802834080501	eu-west-1
205493899709	eu-west-2
254080097072	eu-west-3
601324751636	eu-north-1
966458181534	eu-south-1
746233611703	eu-central-1
110948597952	ap-east-1
763008648453	ap-south-1
941853720454	ap-northeast-1
151534178276	ap-northeast-2
324986816169	ap-southeast-1
355873309152	ap-southeast-2
474822919863	cn-northwest-1
472730292857	cn-north-1
756306329178	sa-east-1

aws_account_id	aws_region
464438896020	ca-central-1
836785723513	me-south-1
774647643957	af-south-1

## Edge Devices

Amazon SageMaker Neo provides compilation support for popular machine learning frameworks. You can deploy your Neo-compiled edge devices such as the Raspberry Pi 3, Texas Instruments' Sitara, Jetson TX1, and more. For a full list of supported frameworks and edge devices, see [Supported Frameworks, Devices, Systems, and Architectures](#).

You must configure your edge device so that it can use Amazon services. One way to do this is to install DLR and Boto3 to your device. To do this, you must set up the authentication credentials. See [Boto3 Amazon Configuration](#) for more information. Once your model is compiled and your edge device is configured, you can download the model from Amazon S3 to your edge device. From there, you can use the [Deep Learning Runtime \(DLR\)](#) to read the compiled model and make inferences.

For first-time users, we recommend you check out the [Getting Started](#) guide. This guide walks you through how to set up your credentials, compile a model, deploy your model to a Raspberry Pi 3, and make inferences on images.

### Topics

- [Supported Frameworks, Devices, Systems, and Architectures \(p. 2063\)](#)
- [Deploy Models \(p. 2072\)](#)
- [Getting Started with Neo on Edge Devices \(p. 2073\)](#)

## Supported Frameworks, Devices, Systems, and Architectures

Amazon SageMaker Neo supports common machine learning frameworks, edge devices, operating systems, and chip architectures. Find out if Neo supports your framework, edge device, OS, and chip architecture by selecting one of the topics below.

You can find a list of models that have been tested by the Amazon SageMaker Neo Team in the [Tested Models \(p. 2067\)](#) section.

### Note

Ambarella devices require additional files to be included within the compressed TAR file before it is sent for compilation. For more information, see [Troubleshoot Ambarella Errors \(p. 2083\)](#).

### Topics

- [Supported Frameworks \(p. 2063\)](#)
- [Supported Devices, Chip Architectures, and Systems \(p. 2065\)](#)
- [Tested Models \(p. 2067\)](#)

## Supported Frameworks

Amazon SageMaker Neo supports the following frameworks.

Framework	Framework Version	Model Version	Models	Model Formats (packaged in *.tar.gz)	Toolkits
MXNet	1.6.0	Supports 1.6.0 or earlier	Image Classification, Object Detection, Semantic Segmentation, Pose Estimation, Activity Recognition	One symbol file (.json) and one parameter file (.params)	GluonCV v0.8.0
ONNX	1.5.0	Supports 1.5.0 or earlier	Image Classification, SVM	One model file (.onnx)	
Keras	2.2.4	Supports 2.2.4 or earlier	Image Classification	One model definition file (.h5)	
PyTorch	1.6.0	Supports 1.6.0 or earlier	Image Classification	One model definition file (.pth)	
TensorFlow	1.15.0	Supports 1.15.0 or earlier	Image Classification	*For saved models, one .pb or one .pbtxt file and a variables directory that contains variables *For frozen models, only one .pb or .pbtxt file	
TensorFlow-Lite	1.13.1	Supports 1.13.1 or earlier	Image Classification, Object Detection	One model definition flatbuffer file (.tflite)	
XGBoost	0.9	Supports 0.9 or earlier	Decision Trees	One XGBoost model file (.model) where the number of nodes in a tree is less than $2^{31}$	
DARKNET			Image Classification, Object Detection	One config (.cfg) file and one weights (.weights) file	

## Supported Devices, Chip Architectures, and Systems

Amazon SageMaker Neo supports the following devices, chip architectures, and operating systems.

### Devices

You can select a device using the dropdown list in the [Amazon SageMaker console](#) or by specifying the `TargetDevice` in the output configuration of the [createCompilationJob](#) API.

You can choose from one of the following edge devices:

Device List	System on a Chip (SoC)	Operating System	Architecture	Accelerator	Compiler Options Example
aisage		Linux	ARM64	Mali	
amba_cv22	CV22	Arch Linux	ARM64	cvflow	
coreml		iOS, macOS			{"class_labels": "imagenet_labels_1000..."}
deeplens	Intel Atom	Linux	X86_64	Intel Graphics	
imx8qm	NXP imx8	Linux	ARM64		
jacinto_tda4vm	TDA4VM	Linux	ARM	TDA4VM	
jetson_nano		Linux	ARM64	NVIDIA	{"gpu-code": "sm_53", "trt-ver": "5.0.6", "cuda-ver": "10.0"}
jetson_tx1		Linux	ARM64	NVIDIA	{"gpu-code": "sm_53", "trt-ver": "6.0.1", "cuda-ver": "10.0"}
jetson_tx2		Linux	ARM64	NVIDIA	{"gpu-code": "sm_62", "trt-ver": "6.0.1", "cuda-ver": "10.0"}
jetson_xavier		Linux	ARM64	NVIDIA	{"gpu-code": "sm_72", "trt-ver": "5.1.6", "cuda-ver": "10.0"}

Device List	System on a Chip (SoC)	Operating System	Architecture	Accelerator	Compiler Options Example
qcs605		Android	ARM64	Mali	{ 'ANDROID_PLATFORM': 27 }
qcs603		Android	ARM64	Mali	{ 'ANDROID_PLATFORM': 27 }
rasp3b	ARM A56	Linux	ARM_EABIHF		{ 'mattr': [ '+neon' ] }
rasp4	ARM A72				
rk3288		Linux	ARM_EABIHF	Mali	
rk3399		Linux	ARM64	Mali	
sbe_c		Linux	x86_64		{ 'mcpu': 'core-avx2' }
sitara_am57x	AM57X	Linux	ARM64	EVE and/or C66x DSP	
x86_win32		Windows 10	X86_32		
x86_win64		Windows 10	X86_32		

For more information about JSON key-value compiler options for each target device, see the [CompilerOptions](#) field in the [OutputConfig API](#) data type.

### Systems and Chip Architectures

The following look-up tables provide information regarding available operating systems and architectures for Neo model compilation jobs.

#### Linux

	X86_64	X86	ARM64	ARM_EABIHF	ARM_EABI
No accelerator (CPU)	X		X	X	X
Nvidia GPU	X		X		
Intel_Graphics	X				
ARM Mali			X	X	X

#### Android

	X86_64	X86	ARM64	ARM_EABIHF	ARM_EABI
No accelerator (CPU)	X	X	X		X

	X86_64	X86	ARM64	ARM_EABIHF	ARM_EABI
Nvidia GPU					
Intel_Graphics	X	X			
ARM Mali			X		X

Windows

	X86_64	X86	ARM64	ARM_EABIHF	ARM_EABI
No accelerator (CPU)	X	X			

## Tested Models

The following collapsible sections provide information about machine learning models that were tested by the Amazon SageMaker Neo team. Expand the collapsible section based on your framework to check if a model was tested.

### Note

This is not a comprehensive list of models that can be compiled with Neo.

See [Supported Frameworks \(p. 2063\)](#) and [SageMaker Neo Supported Operators](#) to find out if you can compile your model with SageMaker Neo.

## DarkNet

Models	ARM V8	ARM Mali	Ambare CV22	Nvidia	Panoram	TI TDA4VM	Qualco QCS603	X86_Linu	X86_Wi

## Deploy Models

You can deploy the compute module to resource-constrained edge devices by: downloading the compiled model from Amazon S3 to your device and using [DLR](#), or you can use [Amazon IoT Greengrass](#).

Before moving on, make sure your edge device must be supported by SageMaker Neo. See, [Supported Frameworks, Devices, Systems, and Architectures](#) to find out what edge devices are supported. Make sure that you specified your target edge device when you submitted the compilation job, see [Use Neo to Compile a Model](#).

### Deploy a Compiled Model (DLR)

[DLR](#) is a compact, common runtime for deep learning models and decision tree models. DLR uses the [TVM](#) runtime, [Treelite](#) runtime, NVIDIA TensorRT™, and can include other hardware-specific runtimes. DLR provides unified Python/C++ APIs for loading and running compiled models on various devices.

You can install latest release of DLR package using the following pip command:

```
pip install dlr
```

For installation of DLR on GPU targets or non-x86 edge devices, please refer to [Releases](#) for prebuilt binaries, or [Installing DLR](#) for building DLR from source. For example, to install DLR for Raspberry Pi 3, you can use:

```
pip install https://neo-ai-dlr-release.s3-us-west-2.amazonaws.com/v1.3.0/pi-armv7l-raspbian4.14.71-glibc2_24-libstdcpp3_4/dlr-1.3.0-py3-none-any.whl
```

## Deploy a Model (Amazon IoT Greengrass)

Amazon IoT Greengrass extends cloud capabilities to local devices. It enables devices to collect and analyze data closer to the source of information, react autonomously to local events, and communicate securely with each other on local networks. With Amazon IoT Greengrass, you can perform machine learning inference at the edge on locally generated data using cloud-trained models. Currently, you can deploy models on to all Amazon IoT Greengrass devices based on ARM Cortex-A, Intel Atom, and Nvidia Jetson series processors. For more information on deploying a Lambda inference application to perform machine learning inferences with Amazon IoT Greengrass, see [How to configure optimized machine learning inference using the Amazon Management Console](#).

## Getting Started with Neo on Edge Devices

This guide to getting started with Amazon SageMaker Neo shows you how to compile a model, set up your device, and make inferences on your device. Most of the code examples use Boto3. We provide commands using Amazon CLI where applicable, as well as instructions on how to satisfy prerequisites for Neo.

### Note

You can run the following code snippets on your local machine, within a SageMaker notebook, within SageMaker Studio, or (depending on your edge device) on your edge device. The setup is similar; however, there are two main exceptions if you run this guide within a SageMaker notebook instance or SageMaker Studio session:

- You do not need to install Boto3.
- You do not need to add the ‘AmazonSageMakerFullAccess’ IAM policy

This guide assumes you are running the following instructions on your edge device.

## Prerequisites

### 1. Install Boto3

If you are running these commands on your edge device, you must install the Amazon SDK for Python (Boto3). Within a Python environment (preferably a virtual environment), run the following locally on your edge device’s terminal or within a Jupyter notebook instance:

Terminal

```
$ pip install boto3
```

Jupyter Notebook

```
!pip install boto3
```

### 2. Set Up Amazon Credentials

You need to set up Amazon Web Services credentials on your device in order to run SDK for Python (Boto3). By default, the Amazon credentials should be stored in the file `~/.aws/credentials` on your edge device. Within the credentials file, you should see two environment variables: `aws_access_key_id` and `aws_secret_access_key`.

In your terminal, run:

```
$ more ~/.aws/credentials

[default]
aws_access_key_id = YOUR_ACCESS_KEY
aws_secret_access_key = YOUR_SECRET_KEY
```

The [Amazon General Reference Guide](#) has instructions on how to get the necessary `aws_access_key_id` and `aws_secret_access_key`. For more information on how to set up credentials on your device, see the [Boto3](#) documentation.

### 3. Set up an IAM Role and attach policies.

Neo needs access to your S3 bucket URI. Create an IAM role that can run SageMaker and has permission to access the S3 URI. You can create an IAM role either by using SDK for Python (Boto3), the console, or the Amazon CLI. The following example illustrates how to create an IAM role using SDK for Python (Boto3):

```
import boto3

AWS_REGION = 'aws-region'

# Create an IAM client to interact with IAM
iam_client = boto3.client('iam', region_name=AWS_REGION)
role_name = 'role-name'
```

For more information on how to create an IAM role with the console, Amazon CLI, or through the Amazon API, see [Creating an IAM user in your Amazon account](#).

Create a dictionary describing the IAM policy you are attaching. This policy is used to create a new IAM role.

```
policy = {
    'Statement': [
        {
            'Action': 'sts:AssumeRole',
            'Effect': 'Allow',
            'Principal': {'Service': 'sagemaker.amazonaws.com'},
        },
        'Version': '2012-10-17'
    ]
}
```

Create a new IAM role using the policy you defined above:

```
import json

new_role = iam_client.create_role(
    AssumeRolePolicyDocument=json.dumps(policy),
    Path='/',
    RoleName=role_name
)
```

You need to know what your Amazon Resource Name (ARN) is when you create a compilation job in a later step, so store it in a variable as well.

```
role_arn = new_role['Role']['Arn']
```

Now that you have created a new role, attach the permissions it needs to interact with Amazon SageMaker and Amazon S3:

```
iam_client.attach_role_policy(
    RoleName=role_name,
    PolicyArn='arn:aws:iam::aws:policy/AmazonSageMakerFullAccess'
)

iam_client.attach_role_policy(
    RoleName=role_name,
    PolicyArn='arn:aws:iam::aws:policy/AmazonS3FullAccess'
);
```

#### 4. Create an Amazon S3 bucket to store your model artifacts

SageMaker Neo will access your model artifacts from Amazon S3

Boto3

```
# Create an S3 client
s3_client = boto3.client('s3', region_name=AWS_REGION)

# Name buckets
bucket='name-of-your-bucket'

# Check if bucket exists
if boto3.resource('s3').Bucket(bucket) not in boto3.resource('s3').buckets.all():
    s3_client.create_bucket(
        Bucket=bucket,
        CreateBucketConfiguration={
            'LocationConstraint': AWS_REGION
        }
)
else:
    print(f'Bucket {bucket} already exists. No action needed.')
```

CLI

```
$ aws s3 mb s3://'name-of-your-bucket' --region specify-your-region

# Check your bucket exists
$ aws s3 ls s3://'name-of-your-bucket'/
```

#### 5. Train a machine learning model

See [Train a Model with Amazon SageMaker](#) for more information on how to train a machine learning model using Amazon SageMaker. You can optionally upload your locally trained model directly into an Amazon S3 URI bucket.

**Note**

Make sure the model is correctly formatted depending on the framework you used. See [What input data shapes does SageMaker Neo expect?](#)

If you do not have a model yet, use the `curl` command to get a local copy of the `coco_ssd_mobilenet` model from TensorFlow's website. The model you just copied is an object detection model trained from the [COCO dataset](#). Type the following into your Jupyter notebook:

```
model_zip_filename = './coco_ssd_mobilenet_v1_1.0.zip'
!curl http://storage.googleapis.com/download.tensorflow.org/models/tflite/
coco_ssd_mobilenet_v1_1.0_quant_2018_06_29.zip \
```

```
--output {model_zip_filename}
```

Note that this particular example was packaged in a .zip file. Unzip this file and repackage it as a compressed tarfile (.tar.gz) before using it in later steps. Type the following into your Jupyter notebook:

```
# Extract model from zip file
!unzip -u {model_zip_filename}

model_filename = 'detect.tflite'
model_name = model_filename.split('.')[0]

# Compress model into .tar.gz so SageMaker Neo can use it
model_tar = model_name + '.tar.gz'
!tar -czf {model_tar} {model_filename}
```

## 6. Upload trained model to an S3 bucket

Once you have trained your machine learning mode, store it in an S3 bucket.

Boto3

```
# Upload model
s3_client.upload_file(filename=model_filename, bucket=bucket, key=model_filename)
```

CLI

Replace `your-model-filename` and `your-S3-bucket` with the name of your S3 bucket.

```
$ aws s3 cp your-model-filename s3://your-S3-bucket
```

## Step 1: Compile the Model

Once you have satisfied the [Prerequisites](#), you can compile your model with Amazon SageMaker Neo. You can compile your model using the Amazon CLI, the console or the [Amazon Web Services SDK for Python \(Boto3\)](#), see [Use Neo to Compile a Model](#). In this example, you will compile your model with Boto3.

To compile a model, SageMaker Neo requires the following information:

### 1. The Amazon S3 bucket URI where you stored the trained model.

If you followed the prerequisites, the name of your bucket is stored in a variable named `bucket`. The following code snippet shows how to list all of your buckets using the Amazon CLI:

```
$ aws s3 ls
```

For example:

```
$ aws s3 ls
2020-11-02 17:08:50 bucket
```

### 2. The Amazon S3 bucket URI where you want to save the compiled model.

The code snippet below concatenates your Amazon S3 bucket URI with the name of an output directory called `output`:

```
s3_output_location = f's3://{bucket}/output'
```

**3. The machine learning framework you used to train your model.**

Define the framework you used to train your model.

```
framework = 'framework-name'
```

For example, if you wanted to compile a model that was trained using TensorFlow, you could either use `tflite` or `tensorflow`. Use `tflite` if you want to use a lighter version of TensorFlow that uses less storage memory.

```
framework = 'tflite'
```

For a complete list of Neo-supported frameworks, see [Supported Frameworks, Devices, Systems, and Architectures](#).

**4. The shape of your model's input.**

Neo requires the name and shape of your input tensor. The name and shape are passed in as key-value pairs. `value` is a list of the integer dimensions of an input tensor and `key` is the exact name of an input tensor in the model.

```
data_shape = '{"name": [tensor-shape]}'
```

For example:

```
data_shape = '{"normalized_input_image_tensor": [1, 300, 300, 3]}'
```

**Note**

Make sure the model is correctly formatted depending on the framework you used. See [What input data shapes does SageMaker Neo expect?](#) The key in this dictionary must be changed to the new input tensor's name.

**5. Either the name of the target device to compile for or the general details of the hardware platform**

```
target_device = 'target-device-name'
```

For example, if you want to deploy to a Raspberry Pi 3, use:

```
target_device = 'rasp3b'
```

You can find the entire list of supported edge devices in [Supported Frameworks, Devices, Systems, and Architectures](#).

Now that you have completed the previous steps, you can submit a compilation job to Neo.

```
# Create a SageMaker client so you can submit a compilation job
sagemaker_client = boto3.client('sagemaker', region_name=AWS_REGION)

# Give your compilation job a name
compilation_job_name = 'getting-started-demo'
print(f'Compilation job for {compilation_job_name} started')
```

```

response = sagemaker_client.create_compilation_job(
    CompilationJobName=compilation_job_name,
    RoleArn=role_arn,
    InputConfig={
        'S3Uri': s3_input_location,
        'DataInputConfig': data_shape,
        'Framework': framework.upper()
    },
    OutputConfig={
        'S3OutputLocation': s3_output_location,
        'TargetDevice': target_device
    },
    StoppingCondition={
        'MaxRuntimeInSeconds': 900
    }
)

# Optional - Poll every 30 sec to check completion status
import time

while True:
    response =
    sagemaker_client.describe_compilation_job(CompilationJobName=compilation_job_name)
    if response['CompilationJobStatus'] == 'COMPLETED':
        break
    elif response['CompilationJobStatus'] == 'FAILED':
        raise RuntimeError('Compilation failed')
    print('Compiling ...')
    time.sleep(30)
print('Done!')

```

If you want additional information for debugging, include the following print statement:

```
print(response)
```

If the compilation job is successful, your compiled model is stored in the output Amazon S3 bucket you specified earlier (`s3_output_location`). Download your compiled model locally:

```

object_path = f'output/{model}-{target_device}.tar.gz'
neo_compiled_model = f'compiled-{model}.tar.gz'
s3_client.download_file(bucket, object_path, neo_compiled_model)

```

## Step 2: Set Up Your Device

You will need to install packages on your edge device so that your device can make inferences. You will also need to either install [Amazon IoT Greengrass](#) core or [Deep Learning Runtime \(DLR\)](#). In this example, you will install packages required to make inferences for the `coco_ssd_mobilenet` object detection algorithm and you will use DLR.

### 1. Install additional packages

In addition to Boto3, you must install certain libraries on your edge device. What libraries you install depends on your use case.

For example, for the `coco_ssd_mobilenet` object detection algorithm you downloaded earlier, you need to install [NumPy](#) for data manipulation and statistics, [PIL](#) to load images, and [Matplotlib](#) to generate plots. You also need a copy of TensorFlow if you want to gauge the impact of compiling with Neo versus a baseline.

```
!pip3 install numpy pillow tensorflow matplotlib
```

## 2. Install inference engine on your device

To run your Neo-compiled model, install the [Deep Learning Runtime \(DLR\)](#) on your device. DLR is a compact, common runtime for deep learning models and decision tree models. On x86\_64 CPU targets running Linux, you can install the latest release of the DLR package using the following pip command:

```
!pip install dlr
```

For installation of DLR on GPU targets or non-x86 edge devices, refer to [Releases](#) for prebuilt binaries, or [Installing DLR](#) for building DLR from source. For example, to install DLR for Raspberry Pi 3, you can use:

```
!pip install https://neo-ai-dlr-release.s3-us-west-2.amazonaws.com/v1.3.0/pi-armv7l-raspbian4.14.71-glibc2_24-libstdcpp3_4/dlr-1.3.0-py3-none-any.whl
```

## Step 3: Make Inferences on Your Device

In this example, you will use Boto3 to download the output of your compilation job onto your edge device. You will then import DLR, download an example images from the dataset, resize this image to match the model's original input, and then you will make a prediction.

### 1. Download your compiled model from Amazon S3 to your device and extract it from the compressed tarfile.

```
# Download compiled model locally to edge device
object_path = f'output/{model_name}-{target_device}.tar.gz'
neo_compiled_model = f'compiled-{model_name}.tar.gz'
s3_client.download_file(bucket_name, object_path, neo_compiled_model)

# Extract model from .tar.gz so DLR can use it
!mkdir ./dlr_model # make a directory to store your model (optional)
!tar -xvf ./compiled-detect.tar.gz --directory ./dlr_model
```

### 2. Import DLR and an initialized DLRModel object.

```
import dlr

device = 'cpu'
model = dlr.DLRModel('./dlr_model', device)
```

### 3. Download an image for inferencing and format it based on how your model was trained.

For the coco\_ssd\_mobilenet example, you can download an image from the [COCO dataset](#) and then reform the image to 300x300:

```
from PIL import Image

# Download an image for model to make a prediction
input_image_filename = './input_image.jpg'
!curl https://farm9.staticflickr.com/8325/8077197378_79efb4805e_z.jpg --output {input_image_filename}

# Format image so model can make predictions
resized_image = image.resize((300, 300))
```

```
# Model is quantized, so convert the image to uint8
x = np.array(resized_image).astype('uint8')
```

#### 4. Use DLR to make inferences.

Finally, you can use DLR to make a prediction on the image you just downloaded:

```
out = model.run(x)
```

For more examples using DLR to make inferences from a Neo-compiled model on an edge device, see the [neo-ai-dlr Github repository](#).

## Troubleshoot Errors

This section contains information about how to understand and prevent common errors, the error messages they generate, and guidance on how to resolve these errors. Before moving on, ask yourself the following questions:

**Did you encounter an error before you deployed your model?** If yes, see [Troubleshoot Neo Compilation Errors](#).

**Did you encounter an error after you compiled your model?** If yes, see [Troubleshoot Neo Inference Errors](#).

**Did you encounter an error trying to compile your model for Ambarella devices?** If yes, see [Troubleshoot Ambarella Errors \(p. 2083\)](#).

## Error Classification Types

This list classifies the *user errors* you can receive from Neo. These include access and permission errors and load errors for each of the supported frameworks. All other errors are *system errors*.

### Client permission error

Neo passes the errors for these straight through from the dependent service.

- *Access Denied* when calling sts:AssumeRole
- Any 400 error when calling Amazon S3 to download or upload a client model
- *PassRole* error

### Load error

Assuming that the Neo compiler successfully loaded .tar.gz from Amazon S3, check whether the tarball contains the necessary files for compilation. The checking criteria is framework-specific:

- **TensorFlow**: Expects only protobuf file (\*.pb or \*.pbtxt). For saved models, expects one variables folder.
- **Pytorch**: Expect only one pytorch file (\*.pth).
- **MXNET**: Expect only one symbol file (\*.json) and one parameter file (\*.params).
- **XGBoost**: Expect only one XGBoost model file (\*.model). The input model has size limitation.

### Compilation error

Assuming that the Neo compiler successfully loaded .tar.gz from Amazon S3, and that the tarball contains necessary files for compilation. The checking criteria is:

- **OperatorNotImplemented:** An operator has not been implemented.
- **OperatorAttributeNotImplemented:** The attribute in the specified operator has not been implemented.
- **OperatorAttributeRequired:** An attribute is required for an internal symbol graph, but it is not listed in the user input model graph.
- **OperatorAttributeValueNotValid:** The value of the attribute in the specific operator is not valid.

## Troubleshoot Neo Compilation Errors

This section contains information about how to understand and prevent common compilation errors, the error messages they generate, and guidance on how to resolve these errors.

#### Topics

- [How to Use This Page \(p. 2081\)](#)
- [Framework-Related Errors \(p. 2081\)](#)
- [Infrastructure-Related Errors \(p. 2082\)](#)

### How to Use This Page

Attempt to resolve your error by going through these sections in the following order:

1. Check that the input of your compilation job satisfies the input requirements. See [What input data shapes does SageMaker Neo expect?](#)
2. Check common [framework-specific errors](#).
3. Check if your error is an [infrastructure error](#).

### Framework-Related Errors

#### TensorFlow

Error	Solution
InputConfiguration: Exactly one .pb file is allowed for TensorFlow models.	Make sure you only provide one .pb or .pbtxt file.
InputConfiguration: Exactly one .pb or .pbtxt file is allowed for TensorFlow models.	Make sure you only provide one .pb or .pbtxt file.
ClientError: InputConfiguration: TVM cannot convert <model zoo> model. Please make sure the framework you selected is correct. The following operators are not implemented: {<operator name>}	Check the operator you chose is supported. See <a href="#">SageMaker Neo Supported Frameworks and Operators</a> .

## Keras

Error	Solution
<code>InputConfiguration: No h5 file provided in &lt;model path&gt;</code>	Check your h5 file is in the Amazon S3 URI you specified. <i>Or</i> Check that the <a href="#">h5 file is correctly formatted</a> .
<code>InputConfiguration: Multiple h5 files provided, &lt;model path&gt;, when only one is allowed</code>	Check you are only providing one h5 file.
<code>ClientError: InputConfiguration: Unable to load provided Keras model. Error: 'sample_weight_mode'</code>	Check the Keras version you specified is supported. See, supported frameworks for <a href="#">cloud instances</a> and <a href="#">edge devices</a> .
<code>ClientError: InputConfiguration: Input input has wrong shape in Input Shape dictionary. Input shapes should be provided in NCHW format.</code>	Check that your model input follows NCHW format. See <a href="#">What input data shapes does SageMaker Neo expect?</a>

## MXNet

Error	Solution
<code>ClientError: InputConfiguration: Only one parameter file is allowed for MXNet model. Please make sure the framework you select is correct.</code>	SageMaker Neo will select the first parameter file given for compilation.

## Infrastructure-Related Errors

Error	Solution
<code>ClientError: InputConfiguration: S3 object does not exist. Bucket: &lt;bucket&gt;, Key: &lt;bucket key&gt;</code>	Check the Amazon S3 URI you provided.
<code>ClientError: InputConfiguration: Bucket &lt;bucket name&gt; is in region &lt;region name&gt; which is different from Amazon Sagemaker service region &lt;service region&gt;</code>	Create an Amazon S3 bucket that is in the same region as the service.
<code>ClientError: InputConfiguration: Unable to untar input model. Please confirm the model is a tar.gz file</code>	Check that your model in Amazon S3 is compressed into a tar.gz file.

## Troubleshoot Neo Inference Errors

This section contains information about how to prevent and resolve some of the common errors you might encounter upon deploying and/or invoking the endpoint. This section applies to **PyTorch 1.4.0 or later** and **MXNet v1.7.0 or later**.

- Make sure the first inference (warm-up inference) on a valid input data is done in `model_fn()`, otherwise the following error message may be seen on the terminal when [predict API](#) is called:

```
An error occurred (ModelError) when calling the InvokeEndpoint operation: Received server error (0) from <users-sagemaker-endpoint> with message "Your invocation timed out while waiting for a response from container model. Review the latency metrics for each container in Amazon CloudWatch, resolve the issue, and try again."
```

- Make sure that the environment variables in the following table are set. If they are not set, the following error message might show up:

**On the terminal:**

```
An error occurred (ModelError) when calling the InvokeEndpoint operation: Received server error (503) from <users-sagemaker-endpoint> with message "{ "code": 503, "type": "InternalServerException", "message": "Prediction failed" }".
```

**In CloudWatch:**

```
W-9001-model-stdout com.amazonaws.ml.mms.wlm.WorkerLifeCycle - AttributeError: 'NoneType' object has no attribute 'transform'
```

Key	Value
SAGEMAKER_PROGRAM	inference.py
SAGEMAKER_SUBMIT_DIRECTORY	/opt/ml/model/code
SAGEMAKER_CONTAINER_LOG_LEVEL	20
SAGEMAKER_REGION	<your region>

- Make sure that the `MMS_DEFAULT_RESPONSE_TIMEOUT` environment variable is set to 500 or a higher value while creating the Amazon SageMaker model; otherwise, the following error message may be seen on the terminal:

```
An error occurred (ModelError) when calling the InvokeEndpoint operation: Received server error (0) from <users-sagemaker-endpoint> with message "Your invocation timed out while waiting for a response from container model. Review the latency metrics for each container in Amazon CloudWatch, resolve the issue, and try again."
```

## Troubleshoot Ambarella Errors

SageMaker Neo requires models to be packaged in a compressed TAR file (\*.tar.gz). Ambarella devices require additional files to be included within the compressed TAR file before it is sent for compilation. Include the following files within your compressed TAR file if you want to compile a model for Ambarella targets with SageMaker Neo:

- A trained model using a framework supported by SageMaker Neo
- A JSON configuration file
- Calibration images

For example, your directory should look similar to the following example:

```
###Mobilenet_v1_1.0_224
```

```

|     ###amba_config.json
|     ###calib_data
|     |     ### data1
|     |     ### data2
|     .
|     .
|     .
|     |     ### data500
|     |     ###mobilenet_v1_1.0_0224_frozen.pb
|

```

The directory is configured as follows:

- `Mobilenet_v1_1.0_224` : The name of file directory that is compressed as a TAR file
- `amba_config.json` : Configuration file
- `calib_data` : Folder containing calibration images
- `mobilenet_v1_1.0_0224_frozen.pb` : TensorFlow model saved as a frozen graph

For information about frameworks supported by SageMaker Neo, see [Supported Frameworks \(p. 2063\)](#).

## Setting up the Configuration File

The configuration file provides information required by the Ambarella toolchain to compile the model. The configuration file must be saved as a JSON file and the name of the file must end with `*config.json`. The following chart shows the contents of the configuration file.

Key	Description	Example
<code>inputs</code>	Dictionary mapping input layers to attribute.	<code>{inputs:{ "data":{...}, "data1":{...} }}</code>
<code>"data"</code>	Input layer name. Note: <code>"data"</code> is an example of the name you can use to label the input layer.	<code>"data"</code>
<code>shape</code>	Describes the shape of the input to the model. This follows the same conventions that SageMaker Neo uses.	<code>"shape": "1,3,224,224"</code>
<code>filepath</code>	Relative path to the directory containing calibration images. These can be binary or image files like JPG or PNG.	<code>"filepath": "calib_data/"</code>
<code>colorformat</code>	Color format that model expects. This will be used while converting images to binary. Supported values: [RGB, BGR]. Default is RGB.	<code>"colorformat":"RGB"</code>
<code>mean</code>	Mean value to be subtracted from the input. Can be a single value or a list of values. When the mean is given as a list the number of entries must match the channel dimension of the input.	<code>"mean":128.0</code>

Key	Description	Example
scale	Scale value to be used for normalizing the input. Can be a single value or a list of values. When the scale is given as a list, the number of entries must match the channel dimension of the input.	"scale": 255.0

The following is a sample configuration file:

```
{
    "inputs": {
        "data": {
            "shape": "1, 3, 224, 224",
            "filepath": "calib_data/",
            "colorformat": "RGB",
            "mean": [128,128,128],
            "scale": [128.0,128.0,128.0]
        }
    }
}
```

## Calibration Images

Quantize your trained model by providing calibration images. Quantizing your model improves the performance of the CVFlow engine on an Ambarella System on a Chip (SoC). The Ambarella toolchain uses the calibration images to determine how each layer in the model should be quantized to achieve optimal performance and accuracy. Each layer is quantized independently to INT8 or INT16 formats. The final model has a mix of INT8 and INT16 layers after quantization.

### How many images should you use?

It is recommended that you include between 100–200 images that are representative of the types of scenes the model is expected to handle. The model compilation time increases linearly to the number of calibration images in the input file.

### What are the recommended image formats?

Calibration images can be in a raw binary format or image formats such as JPG and PNG.
